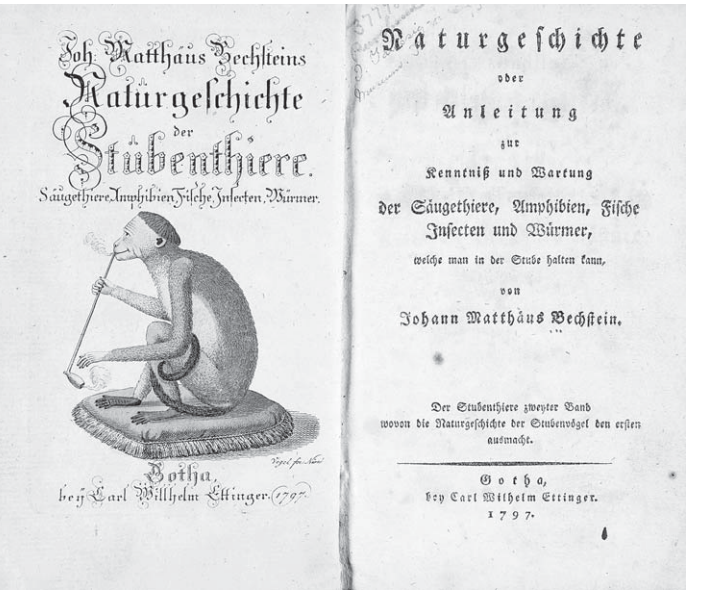
Illustration of public aquarium in Jardin Zoologique d'Acclimatation in Paris from *Le Jardin d'acclimatation illustré: Animaux et plantes / par Pierre-Amédée Pichot ... Avec une préface par M. Albert Geoffroy-Saint-Hilaire . . .*

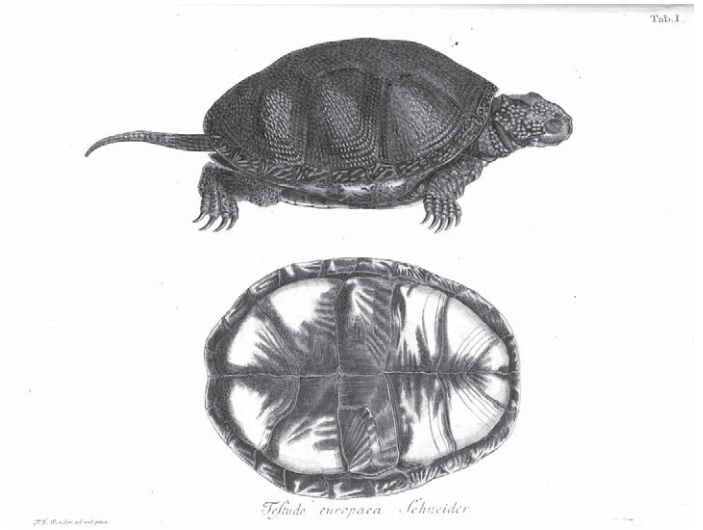


Imprint: Paris, Hachette et cie [etc.] 1873. Credit: Courtesy of Polly Lasker, Smithsonian National Zoological Park.

Public interest in aquatic organisms gave rise to three public aquariums in Europe: Natura Artis Magistra in Amsterdam in 1838, London Zoo in 1858, and Jardin d'Acclimatation in France in 1873.

But then interest in aquaria began to slow down as well. "Some years ago, a complete aquarium mania ran through the country. . . The fashionable lady had magnificent glass-plated aquaria in her drawing room, and the schoolboy managed to keep an aquarium of lesser pretensions in his study. . . So, in due course of time, nine out of every ten aquaria were abandoned; many of the shops were given up, because there was no longer any custom; and to all appearance the aquarium fever had run its course, never again to appear, like hundreds of similar epidemics." (Wood 1859).

Reptiles and Amphibians Are Added to the Mix



Johann Matthaeus Bechstein wrote the first book on captive care of domestic animals and pets in 1797. This intriguing volume was called *Naturgeschichte; oder, Anleitung zur Kenntniss und Wartung der Säugethiere, Amphibien, Fische, Insecten und Würmer, welche man in der Stube halten kann* (Natural History; or, Guide to the Knowledge and Care of Mammals, Amphibians, Fish, Insects and Worms Which Can Be Kept in the Home). His book dealt with five herp species: European Pond Turtle (*Testudo orbicularis*, now *Emys orbicularis*), Common Treefrog (*Rana arborea*, now *Hyla arborea*), sand lizard (*Lacerta agilis*), Great Crested Newt (*Lacerta palustris* and *lacustris*, now *Triturus cristatus*) and European Grass Snake (*Coluber Natrix*, now *Natrix natrix*). The terms aquarium, terrarium, or vivarium had not yet arrived and plate glass was not widely available, so Bechstein used descriptors like little boxes, buckets, sugar glasses, containers made of porcelain, stoneware and so on (Heichler and Murphy 2004).

Engraved title page and printed title page of *Naturgeschichte; oder, Anleitung zur Kenntniss und Wartung der Säugethiere, Amphibien, Fische, Insecten und Würmer, welche man in der Stube halten kann* by Johann Matthaeus Bechstein in 1797. Published in color in *Herpetological Review* 2004, 35(1):8–13.

Nathaniel Ward discovered a robin trapped in his fern-house—it lived and thrived for six months until escaping. This episode gave him the idea of developing the vivarium. He described this idea in an article called "On vivaria" in the *Garden Chronicle* in 1855.

When the reptile building opened at the London Zoo in 1849 and the collection needed to be expanded, zoo employees exchanged herps with private fanciers to fill in the gaps (Keeling 1992). One such example was C. R. Walker at the establishment called "The Vivarium" who sent twenty-five assorted skinks, geckos (possibly *Naultinus*?) from New

Johann Matthäus Bechstein on the Commendable Characteristics of the European Pond Turtle (translated from German): "It cannot be said that their movements are varied or beautiful, or that these animals may be counted among those which are entertaining; however, their very rarity, and the desire to have something alive also from this class of animals under one's care and supervision makes them attractive to the amateur. They can also be fattened up so as to make use of their tasty (even though hard to digest) meat, once the eyes have been satisfied by their sight. Already clever experiments have been made with these animals: Mr. Merz in Paris shut the mouth of one with wire and closed up the nostrils with sealing wax; nevertheless the animal lived another 30 days without food or breathing. This reveals the tenacious vitality which these animals possess."

Zealand, and treefrogs. In addition to the exchanges, many private parties generously donated rare and unusual amphibians and reptiles to the Zoo, such as Long-Nosed Crocodiles, Radiated Tortoises, and a variety of cobras, African Rock Pythons, Emerald Tree Boas, and a multitude of European taxa.

The Exeter Exchange in London was a famous menagerie, beginning in the 1770s and lasting until 1829, which specialized in the sale of exotic reptiles. In 1810, the menagerie was acquired by Edward Cross, who renamed the operation the "Royal Grand National Menagerie" and developed a thriving commercial supply company with customers in Europe and the US. Another well-known dealer in London was a Mr. Kendrick who assured his clients that every reptile for sale came from "Brazil," including Red-eared Sliders, Painted Turtles, and Chameleons (Coote 2001).

In 1884, Johann von Fischer from Vienna, known by many as the founder of modern herpetoculure, published *Das Terrarium, seine Bepflanzung und Bevölkerung*, with recommendations for aquaria and terraria design, plants suitable for the terrarium, food and feeding, and detailed descriptions of the husbandry requirements for a wide array of amphibians and reptiles; his book is accompanied by many drawings. In addition to his book, Johann von Fischer published detailed descriptions on the maintenance and behavior of other captive herpetofauna, many of which were published in the journal *Der zoologische Garten* (see Murphy, 2005 for list). In his book (1884), Johann von Fischer listed his recommendations for amphibian and reptile combinations in various mixed-species terrariums. His lists were long and varied, and filled with rare taxa. What seems true is that there were many sources throughout the world for obtaining herps to be sold in Europe. One example should suffice: taxa which can be kept in the "Chamaeleonshaus" with the Common Chameleon (*Chamaeleo chamaeleon*): *Platydactylus*, *Hemidactylus*, *Ptyodactylus*, *Phyllodactylus*, *Spaeriodactylus*, *Gymnodactylus*, *Stenodactylus*, various *Phrynosoma*, *Ecphymotes torquatas*, *Stellio vulgaris*, *S. cyanogaster*, *Tropidosaura algira*, *Psammosaurus Edwardsii*, young *Scuicus officinalis* and *Gongylus ocellatus*, *Seps chalcides*, *Heteromeles mauritanicus*, *Ophiomorus miliaris*, and *Typlops vermicularis* (nomenclature follows J. v. Fischer).

In 1884 Johann von Fischer published *Das Terrarium, seine Bepflanzung und Bevölkerung*. Shown here is Tuberculated Iguana (*Iguana tuberculata*, now *Iguana iguana*).

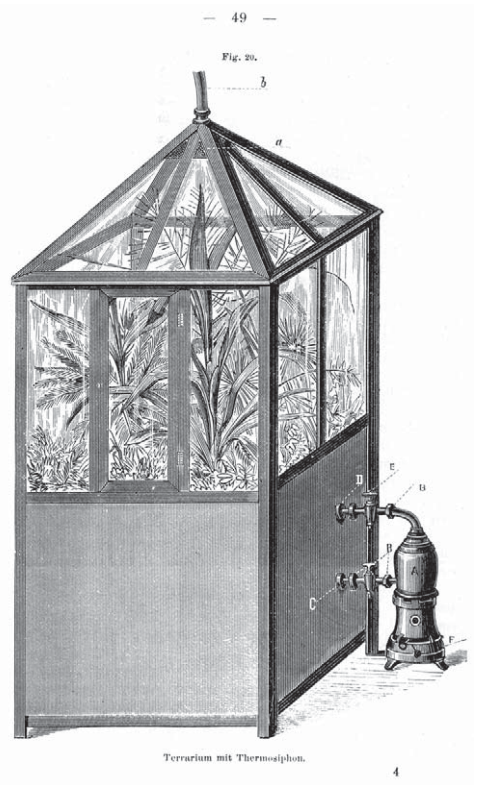

Illustration of Terrarium with "Thermosiphon" for temperature control from *Das Terrarium, seine Bepflanzung und Bevölkerung.*

The first book on herpetoculture in English was the Reverend Gregory Climenson Bateman's *The Vivarium*, published in 1897. There were many advertisements for animals, plants, and supplies in his book. According to Bateman, a broad range of live reptiles and amphibians were obtainable in London in 1897. In addition to the common European species, a number of rarer exotic types were offered for sale: Small Monitor Lizards, Common and Red Tegus, Bearded Dragons, young American Alligators and Crocodiles, Diamond Pythons, African Rock Pythons approximately 4 feet long, Ball Pythons, Anacondas, Horned Frogs, Giant Salamanders, and Olms. Remarkably, Tuataras were accessible, described by Bateman: "Some time ago, I was looking at the various animals in a very large dealer's establishment, when I made a remark about a fine pair of Tuateras which I saw in a big cage. The assistant who was with me immediately opened the door of the den and seized one of the reptiles by the tail, and I shall not readily forget the ominous sound made by the animal's closing jaws as he just missed the man's fingers, at which he had just snapped. I at once mentally resolved never to catch a Tuatera by the tail. As I congratulated the man upon his escape, he said, 'I am a bit lucky this time, for I have just come out of the 'orspital, where I have been laid up with blood-poisoning through the bite of one of them pythons.'"

Bateman also published on aquarium construction, captive husbandry of plants, weeds, fishes, mollusks, insects, etc, and management of freshwater and marine aquaria. Murphy (2007) provided a list of amphibians and reptiles with prices which were available in London during the time.

Aquarium, Vivarium, & Fern Case Manufacturers, Rockworkers, &c.

THE rapid and general appreciation of the Vivarium in the last few years has caused us to largely import and cater for the stocking of same. We have now collectors in Algiers, Cairo, Alexandria (Africa), Bologna, Rome (Italy), Berlin, Vienna, Buda Pesth, Sydney, Paris, &c., and nearer home, so we have no hesitation in asking new and old patrons to write to us for our list from time to time.

When we say that the Professors of Owen's College (Manchester), University College (Liverpool), University (Edinburgh), Royal College of Science (Dublin), Queen's College (Cork), &c., patronise us largely, and solely rely on us for special reptiles, &c., it speaks for itself.

In the Manufacturing Department we are able to compare most favourably with others, and in addition to our sixteen-page Illustrated Catalogue we will send a sketch and price of any new idea that our patrons wish carried out. As a proof of the soundness of our work, Mr. Walmsley, Manager, Blackpool Aquarium, has engaged our Mr. Clifton to make sixty Vivaria (various sizes) for the next season.

[COPY.]

Brighouse, July 10th, '97.

Dear Sir,—Permit me to give you a perfectly unsolicited testimonial, not only as to the value of your wares, but also as to the *base fides* of yourself. I have done business with you for years, and *every* transaction I have had with you has been executed with a completeness and promptitude beyond compare. The specimens dealt in by yourself and the prices charged for them compare most favourably with those charged by the best London, Parisian, and Continental wholesale dealers, with whom I am frequently in contact.

Faithfully yours,

MR. ERNEST CLIFTON. HENRY J. BARBER.

Advertisements for animals and equipment from Reverend Gregory Climenson Bateman's *The Vivarium*, published in 1897. Bateman offered sage advice for the herpetoculturist in 1897. "In the construction of Vivaria, all chance of the captive's escape should be avoided as far as possible. For it is rather mortifying to realise the loss of a valuable Snake, or a favourite lizard; nor does one get much encouragement in a hobby of this kind should he be often obliged to ask the ladies or servants of his home if they may happen to have seen anything of the missing Reptiles."

At the end of the 19th Century, Tuataras were offered for sale by London animal dealers. Reverend Bateman purchased a pair from the London Zoo for £2.00 ($3.00 US). John Edward Gray had described the "Tuatera" from New Zealand in his *The Zoological Miscellany* in 1842, naming it *Hatteria punctata* and placing the taxon in the lizard family Agamidae. Today it is called Tuatara (*Sphenodon punctatus*) and placed in the Suborder Rhynchocephalia. This lovely plate (#20) is from *The Lizards of Australia and New Zealand in the Collection of the British Museum* by Gray, 1867.

Carl Hagenbeck Senior is a name known by virtually every zoo and aquarium professional for in 1907 he developed one of the finest zoos in the world in Hamburg, Germany: Carl Hagenbeck's Tierpark at Stellingen. He built the first exhibits without bars for zoos and served as a design consultant for zoos throughout the world. From 1841 until 1863, he ran a small pet shop featuring exotic animals, including reptiles such as boas and pythons. Later in 1866, his son Carl Junior took over the reins and built the operation into a major animal supplier, sending reptiles to dealers and zoos throughout the world (Coote 2001).

Oskar Boettger described a unique herpetological cooperative arrangement in his paper *Bericht über die Leistungen* in 1890: "Regarding the purpose and setup of the Laboratoire d'Erpetologie in Montpellier [France], a trading and buying organization, one finds information in Humboldt (Dammer), Volume 8, pages 34–35." [translated from German in *Archiv für Naturgeschichte* on p. 160.]. This paper in Humboldt is here loosely translated with some comments in parentheses to clarify how the text was interpreted: "The Laboratoire d'Erpetologie in Montpellier is an organization that exchanges and sells under the direction of our worthy colleague, the well-known herpetologist Dr. J. v. Fischer. The Laboratoire, in which salesmen (researchers would be a better word) can offer living wares, encompasses 147 members throughout Europe and 203 in other parts of the world. The purpose of the organization is to offer reptiles and amphibians of all sorts to members at cost and to make the study of these animals easier. The excess (surplus animals) are released and the profits are divided among members. Donated animals are not sold. Each member is obligated annually to publish two articles in a domestic or foreign publication. The honorarium for

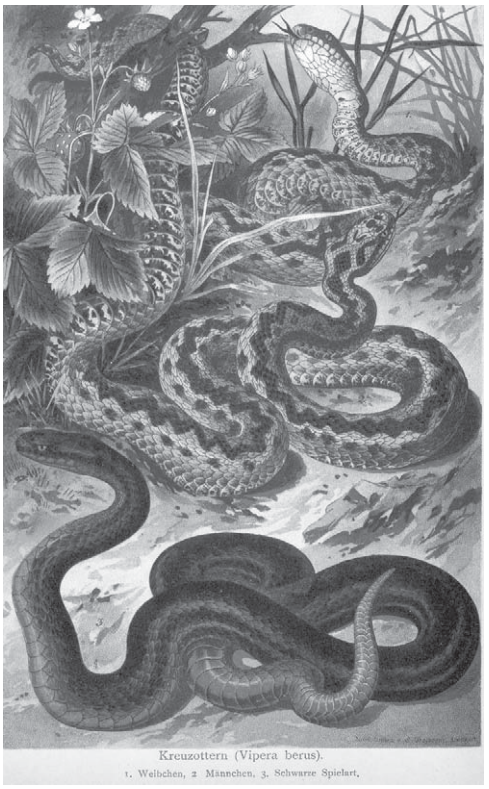
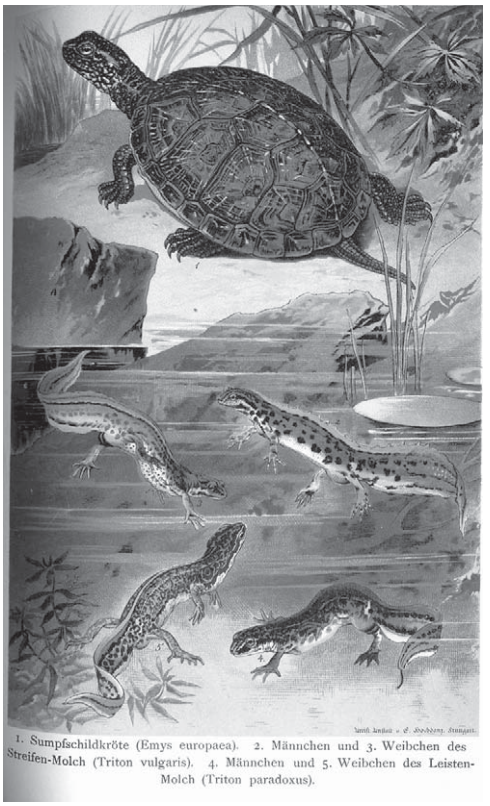
each publication is given to the organization and at the end of the fiscal year is allotted equally. In addition, these colleagues take charge of distributing the excess animals and disposing of dead animals and retain 50% of the profit. The Laboratoire has a fund donated by members to encourage young people to go to unexplored provinces or regions of the world to collect and learn. In addition, for the best collectors there are prizes, which include a microscope from Zeiss in Jena, books, or further travel. Anyone can become a member as long as he demonstrates that he works in this field. Members must prove that they give any uncommon animals to appropriate institutions at no cost if they (the institution) promise to publish accounts of the animals. They keep the honorarium. Eventually a society journal will appear. Each violation—so far there have been none—will result in ejection from the society. The personal word of honor is the only guarantee other than the signature of the member. No hearing will be held, but his name will be circulated as 'manquant a sa parole' (a breaker of his word). The institute up to this point makes a profit of about 1000–1200 francs. The director holds sole responsibility for leadership and is only assisted by a book keeper."



Paul Krefft wrote a major guide to terrarium science in 1908 called *Das Terrarium* with many illustrations of aquaria and terraria. Pictured here are living plants suitable for the terrarium.



Strolling on the promenade in 19th Century Paris with a live turtle was all the rage, as described by Walter Benjamin in his essay: "Around 1840, it was briefly fashionable to take turtles for a walk in the arcades. The *flâneurs* [idlers] like to have the turtles set the pace for them. If they had had their way, progress would have been obliged to accommodate itself to this pace . . . this attitude did not prevail."

A number of books and articles on herpetoculture began to appear after the Bateman volume. Hugo Kukhoff's *Das Terrarium und seine Bewohner: ein kurzer illustrierter Ratgeber für Terrarienfreunde* was written around 1903. Five years later, Paul Krefft wrote a seminal guide to terrarium science called *Das Terrarium.* Dr. Ernst Bade published *Praxis der Terrarienkunde,* a slim volume filled with pictures of terraria and suitable inhabitants for the enclosures. *The Freshwater Aquarium and its Inhabitants; A Guide for the Amateur Aquarist with Many Illustrations from Nature* by Otto Eggeling and Frederick Ehrenberg, written in 1908, had many references to captive herps.

There were books that combined the amateur literature on herp keeping with professional literature, such as Robert Snedigar's *Our Small Native Animals: Their Habits and Care* (1939) and Vinson Brown's *How to Make a Miniature Zoo* (1956). Raymond L. Ditmars of the Bronx Zoo popularized captive herps in his many books during the early part of the 20th Century although he did not write a specific guide to herp keeping.

During the second half of the 20th Century, books and papers on captive amphibians and reptiles exploded on to the scene. In 1955, Wilhelm Klingelhöffer, a German medical doctor, compiled an extraordinary treatment of reptiles and amphibians in captivity called *Terrarienkunde.* This four volume work was the "bible" for European zoo workers and herpetoculturists. Six years later, Alfred Leutscher, founder and secretary of the British Herpetological Society wrote *Vivarium Life.*

Some books on keeping amphibians and reptiles in captivity had beautiful artwork. These original colored drawings are from Ernst Bade's *Praxis der Terrarienkunde* in 1907. Also shown is a terrarium from the period.

A Manual on Amphibians, Reptiles and Cold-Water Fish.

Around 1952 in Great Britain, there were three main suppliers: Palmers of Camden Town; South-Western Aquarists of Glenburnie Road, Balham, owned by George Boyce; and Robert Jackson from Altrincham, Cheshire. Most of the stock was from Europe: Grass Snake, Tessellated Water Snake, Aesculapian Snake, Four-lined Ratsnake, Wall Lizard, Jewelled or Eyed Lizard, Berber Skink, European Pond Turtle, Spur-Thighed and Hermann's Tortoises, and Spanish Terrapin (Keeling, 1992).

Germany was and continues to be one of the strongest centers for herpetoculture. For example, a recent catalogue by the antiquarian book dealer Chimaira in Frankfurt/Main, lists hundreds of titles in German and English dealing with captive amphibians and reptiles. In the book *Die Geschichte der Herpetologie und Terrarienkunde im deutschsprachigen Raum* (edited by Rieck, W., et al., 2001; p. 263), a contribution by Gerhard Hallman is titled as "A selection of traders that offer animals for terrariums, or terrarium technology to the society and its members through ads or price lists." Hallman wrote, "The number of specialty traders that handle reptiles is large. . .The following list, with no aspiration to being complete, attempts to demonstrate this." Then, the chapter shows names of dozens of dealers between 1950 and 2001 in a variety of countries and includes some lists of the herps available as well as their prices. People today might believe that reptile shows or expos are a recent phenomenon but in chapters written by Werner Rieck, there are three fascinating photographs of enormous shows held in Germany in the years 1896 [p. 47], 1908 [p. 50], and 1924 [p. 71].

In the UK from the mid-1960s onwards, the most important resource for the herpetoculturist was the book by Zdeněk Vogel entitled *Reptiles and Amphibians. Their Care and Behaviour* (J. Coote, pers. comm.). In 1969 and 1972, Günther Nietzke summarized much of what was known about terrarium animals in two volumes: (1) Construction, Technical Equipment, and Planning of Terraria; (2) Care and Feeding of Terrarium Animals. The set was called *Die terrarientiere: Bau, technische Einrichtung und Bepflanzung der Terrarien: Haltung, Fütterung und Pflege der Terrientiere in zwei Bänden.*

As ideas, protocols and technologies improved for keeping herps in zoos, two of the most important persons disseminating this vital information were Carl F. Kauffeld at the Staten Island Zoo, and Hans-Günter Petzold at Tierpark Berlin-Friedrichsfelde. Kauffeld deserves special mention, for in addition to his classic *Snakes: The Keeper and the Kept*, he wrote many papers on captive management. Petzold's book (1982), translated from German and published by SSAR in 2008, is the most thorough overview of captive management currently available: *Petzold's The Lives of Captive Reptiles* (see HR 2009, 40:471–472 for review). Later, other zoo workers published books on terrarium keeping: Eugène Bruins (1999) from Natura Artis Magistra in Amsterdam, and Sergei Kudryavtsev and associates (1991) from the Moscow Zoo.

With numbers of captive herps increasing, there was a need to address medical management. H.-H. Reichenbach-Klinke published the first book on the topic called *Krankheiten der Amphibien* in 1961 and *Krankheiten der Reptilien* two years later. An English version was available in 1965 by Reichenbach-Klinke and E. Elkan: *The Principal Diseases of Lower Vertebrates.* For a complete list of titles, consult Murphy (2007; Table 2.1).

The SSAR published two other books on captive and medical management: *Reproductive Biology and Diseases of Captive Reptiles* (Murphy and Collins, 1980) and *Captive Management and Conservation of Amphibians and Reptiles* in 1994 (Murphy et al.). It is beyond the scope of this contribution to list all of the books, serials and papers that have been valuable to our understanding of captive animals but many references have been published in the four-part series called "Updating the Bookshelves" in *Herpetological Review* during 2008–9.

The herpetoculturist of today owes much to his or her predecessors who developed the beautiful and ornate planted terrariums filled with exotic foliage, the heavily planted aquaria, the spectacular semi-aquatic vivaria placed on pedestals in the drawing room with fishes and herps, and the arresting terrestrial terraria filled with mesic or xeric plants, truly a showcase in the home. It is not surprising that there are dealers specializing in antique aquaria and terraria to this day for these are often lovely works of art. Animal collectors and dealers filled a void: they provided specimens from exotic locales that were out of reach to the average fancier.

Acknowledgments.—This paper is dedicated to the late Carl Kauffeld and Harry W. Greene. When one of us (KM) wrote letters full of questions about herpetology, each took his valuable time and responded in writing to the inquiries of a fourteen-year old boy. We thank David Barker, Judith Block, David Chiszar, Jon Coote, Gary Ferguson, Rick Hudson, John Moriarty, Louis Porras, John Simmons, and Trooper Walsh for reviewing early drafts and suggesting improvements. Smithsonian Librarians Polly Lasker, Leslie Overstreet, and Daria Wingreen allowed us to examine publications under their care and arranged loans of obscure books and papers. Margie Gibson and Lucian Heichler assisted with translations. We are grateful to Emily Becker, Dana Fisher, and James Hanken from the Museum of Comparative Zoology, Harvard University for providing illustrations.

The opinions expressed in this article are those of the authors and do not necessarily represent the opinions of any organization.

Yale University Press, New Haven, Connecticut ["In the background of Darwin's studies was a development that gripped all of England in the nineteenth century. Never before could so many animals have been found in bourgeois living rooms, ensconced on their sofas, easy chairs, side-tables and carpets. Within a few decades, the middle class had populated their homes with parakeets in cages, and dogs and cats in baskets. In response to the displacement, industrialisation, and urbanisation that had banished them to life in separate worlds, some groups of humans and animals drew closer together than they ever had been before: the bourgeois and their pets

and zoo animals. In a historical sense, these animals thus came to be seen in a new light: they served not just as a kind of ersatz nature or exotic showpieces for the Victorian bourgeoisie, but also as a means to understand the proximity of humans and animals to one another." (p. 217). Carl Gans (1923–2009) and the Integrative Biology of Reptiles

KRAIG ADLER
Department of Neurobiology and Behavior, Cornell University
Ithaca, New York 14853–2702, USA
e-mail: kka4@cornell.edu

Carl Gans, the preeminent specialist on reptilian biology of his generation, died on 30 November 2009 at the age of 86. This occurred after nearly a decade of poor health that followed a stroke in January 2001. Originally trained as a mechanical engineer, Gans made contributions to the systematics, comparative and functional morphology, physiology, biomechanics, and behavior of reptiles and, to a lesser extent, amphibians, all within an evolutionary context. His ability to integrate diverse approaches to life science—a field today called "integrative biology" that he helped to pioneer—was unrivaled, both conceptually and technically, and has laid the foundation for numerous studies across a broad spectrum by other biologists around the world.

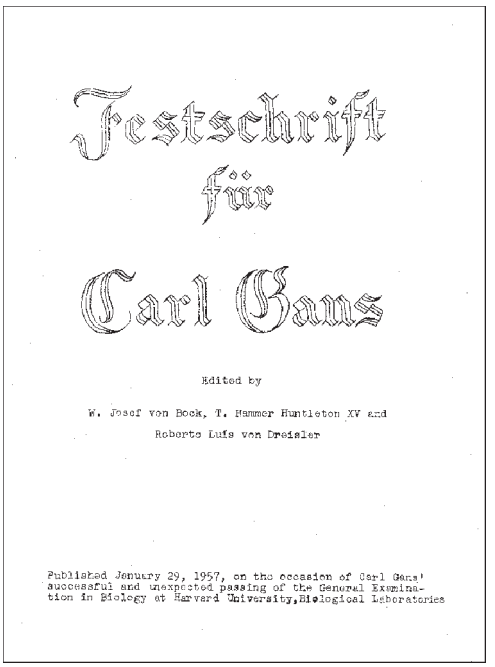
In his laboratory at the University of Michigan with an Australian skink, *Tiliqua rugosa* (ca. 1997). Photo courtesy Robert Dudley.

Carl Gans was born in Hamburg, Germany, on 7 September 1923 where he attended the Talmud Thora Realschule. In his early teens while still in Germany, he loved to read books by the German storyteller, Karl May, first-person narratives about overseas explorations, especially in Asia, and collecting exotic animals. May's books were fiction because he never left Germany until very late in his life. Nevertheless, these volumes made a real impression on Carl who later enjoyed extensive international travel in search of unusual reptiles and amphibians. These books were important enough for him to purchase English translations of them that were still in his home library at his death.

The Gans family immigrated to the United States as Jewish refugees in 1939 and settled in New York City where Carl finished his schooling at George Washington High School. They lived in Upper Manhattan near the George Washington Bridge and on Sundays Carl would walk across this mile-long span to the wet undeveloped lands and high cliffs of the New Jersey Palisades along the Hudson River to capture frogs and snakes for his collection. His first herpetological paper, in *Copeia* in 1945, reported on salamanders and snakes he caught near the Harlem River on Manhattan. He discovered a natural population of the Dusky Salamander (*Desmognathus fuscus*) there, the first report on the island since C. S. Rafinesque's in 1820, and he appealed for it to be conserved. (A breeding population was reported from the site as recently as 2005.) Despite this early interest in animals (and conservation), his father insisted that he would financially support him in college only on the condition that he choose a practical career, so he studied mechanical engineering at New York University (B.Mech.Eng. 1944) and then joined the U.S. Army Corps of Engineers. After basic training, he served in the Pacific Theater during World War II, first in the Philippines and then in Japan. It was then the practice of the U.S. Government not to send soldiers overseas unless they were U.S. citizens; accordingly, Gans was naturalized in January 1945, just before departing for the Pacific. He was slated to be part of the invasion of Japan, clearing beaches with the engineering unit to which he was assigned in the Philippines.

After discharge from the army in September 1946, Gans was hired as a mechanical engineer by Babcock and Wilcox Co. of New York City (1947–1955) to install power boilers in electric generating stations in Pennsylvania and Ohio. Through home study courses he completed a graduate degree in mechanical engineering at Columbia University (M.S. 1950), the year his father died. He had begun to publish on herpetological topics in the mid-1940s including notes on the breeding dates of rhacophorid frogs based on observations he had made in Japan, a bibliography of the herpetology of Japan, and an article on adaptations for egg-eating in a Japanese ratsnake, but Gans continued his career as an engineer. He held several patents for devices he had invented. One of his early engineering ideas, never realized, was the development of automobile headlights that would follow the road.

During 1953–1954, Gans took leave from his job to do fieldwork in Brazil and Bolivia supported by a Guggenheim Memorial Foundation fellowship, during which time he was introduced to amphisbaenians, fossorial squamates that were to become one of his favorite subjects for studies in systematics and functional morphology. He duly returned to his engineering position in 1954, but by then his career goals had radically changed. In 1955, he was accepted as a doctoral student in biology at Harvard University by the vertebrate morphologist, paleontologist, and doyen of American zoologists, Alfred Sherwood Romer. At the age of 32, Gans embarked on an entirely new career in biology and on a fast track. Ernest E. Williams, curator of herpetology in the Museum of Comparative Zoology at Harvard, eventually became his doctoral advisor and by 1957 Gans had completed his dissertation.



Because of his relative seniority to the other graduate students and his esteemed position among them, his professors and fellow graduate students played a good-humored prank on him by issuing a booklet of articles—entitled "Festschrift für Carl Gans"—on the occasion of his "successful and unexpected passing" of his general examination. Inside the booklet there was a table showing major events in Carl's life in the first column and corresponding world events in the other. A sampling: "Born 1923 in Germany" vs. "Panic, inflation and great distress in Germany"; "Left Germany in 1939" vs. "World War II starts"; and "Enters Harvard

in 1955" vs. "President Eisenhower has a heart attack." Even Carl's professors had some fun: "He has done so little in his life so far and yet that little has disturbed the world so much (E. E. W[illiams].)."

As a senior graduate student at Harvard University (about 1957). Photo courtesy Kraig Adler.

Gans's dissertation combined his interests in engineering and evolution, as well as his keen observational skills, in a study of the African egg-eating snakes (*Dasypeltis*) from which he drew major insights. (He had begun to publish on the egg-eating adaptations of *Dasypeltis* in 1952, based on his private research.) He described the morphological and biomechanical adaptations that allow these nearly toothless snakes to eat large eggs, crack the shells within the esophagus, empty out the liquid contents, and regurgitate the shell as a cigar-shaped mass. Later, he used vector analysis to describe in trigonometric terms the initial swallowing process, among other actions. He also discovered that the color patterns of these snakes varied geographically and in parallel to those of several small vipers (*Bitis*, *Causus*, and especially *Echis*). These, in addition, display C-shaped coiling behaviors and, in *Dasypeltis* and *Echis*, stridulating warning reactions when disturbed. He recognized that the color pattern and behavioral convergence of these snakes represented an example of Batesian mimicry and then extended this idea to develop a new concept of "empathic learning" that explains how mimicry can evolve even when the model is lethal. This project, integrating Gans's interests in systematics, morphology, biomechanics, and evolution, provided the pattern for his highly versatile research career.

Cover of the spoof booklet, "Festschrift für Carl Gans," prepared by fellow students and professors at Harvard University on completion of his doctoral studies (1957). Photo courtesy Kraig Adler.

On completing his doctoral work, Gans became a postdoctoral fellow at the University of Florida before joining the faculty of the University of Buffalo in western New York State in 1958. His most extensive publication from this period was his book-length monograph, "A Taxonomic Revision of the African Snake Genus *Dasypeltis*" (1959). He quickly rose from assistant professor to full professor and by 1970 was chairman of the biology department. The next year he moved to the University of Michigan, which had long been a prominent center for herpetological research and graduate education, as chairman of the zoology department (1971–1975). He was a hard-driving leader of the department who set very high standards for his faculty and became the nemesis of the botany department, which shared a building with zoology and competed for the same space. After retiring as professor in 1997, Gans moved to Austin, Texas, where he was an adjunct professor at The University of Texas.

Gans's research program covered a very broad scope including functional morphology (mainly of vertebrates), systematics of reptiles, the evolution of early vertebrates, and adaptations of limbless and burrowing tetrapods (mainly caecilians, amphisbaenians, and uropeltid snakes). His pioneering studies on the origin of vertebrates focused on the invention of the head (and thus the neck), which was made possible by the evolution of a new kind of embryonic cell (called neural crest) that he believed led to bone. This project was conducted together with his former zoology colleague at Michigan, R. Glenn Northcutt, and arose from their teaching a course on the comparative anatomy of vertebrates.

Carl took an engineer's approach to studying and experimenting with functional problems such as locomotion, burrowing, feeding (especially chewing), respiration, sound production, and hearing, all studied from an evolutionary perspective. His classic studies on breathing in frogs were conducted primarily in collaboration with a Dutch functional morphologist, H. J. de Jongh. They used sophisticated technologies in their work (electromyography, cinematography, and cinefluorography; monitoring buccal and pulmonary pressures; and recording gas flow in frogs placed in atmospheres with variable concentrations of argon and nitrogen) and demonstrated that relatively pure air was pumped into the lungs. Carl's favorites, the amphisbaenians, provided yet other models for application of biomechanical analysis. These burrowing wormlizards propel themselves underground using concertina and rectilinear mechanisms and he discovered that significantly different digging methods were employed among the families of wormlizards. Gans's textbook, "Biomechanics: An Approach to Vertebrate Morphology" (1974) summarized much of his early work in functional morphology and has become the standard sourcebook for the field.

First and foremost, however, Gans was a naturalist who loved reptiles and was fascinated with the ways in which they lived their lives. He was equally at ease studying them in the lab as he was in the field and regularly made numerous trips overseas to study them in South America, Africa, Australia, and especially in India and Sri Lanka. He collaborated and published regularly with numerous biologists at universities and museums throughout the world. He was also a major proponent of the value of collaborations with herpetologists at zoos. Although relatively few graduate students took their degrees with Carl, many colleagues and their students flocked to work with him on joint projects. His wife, Kyoko A. (Mabel) Gans, who had been the executive secretary of the biology department at Harvard and who he married in 1961, actively supported his research, writing, and editing and she graciously hosted legions of visitors who came to work with Carl. They were a real team until she died of cancer in 1999.

Besides his personal research contributions, Gans served the biological community in numerous ways. He was president of several major societies (American Society of Ichthyologists and Herpetologists, American Society of Zoologists [now called Society for Integrative and Comparative Biology], and Society for the Study of Amphibians and Reptiles) and served as editor of the *Journal of Morphology* for 25 years. While still a postdoc at Florida, he joined SSAR during its first year (1958) and under its former name, The Ohio Herpetological Society. When he discovered that it was run by a bunch of teenagers, he promptly resigned. He rejoined OHS a few years later, however, and in 1967 showed up for the 10th Anniversary Meeting in Columbus, Ohio, and thereafter became a regular participant in society meetings. He became involved in many other society activities and helped to draft the new SSAR Constitution

As president of SSAR, together with the presidents of the American Society of Ichthyologists and Herpetologists (Marvalee Wake) and The Herpetologists' League (Ronald Brandon), at the Joint Meeting of Ichthyologists and Herpetologists at the University of Oklahoma (August 1984). Photo by Kraig Adler.

in 1970. As SSAR president for 1984, he was an activist leader who enjoyed his freedom to innovate without the encumbrance of an overly circumscriptive society constitution.

Carl's supreme achievement in his service to our discipline, however, was the 22-volume series, "Biology of the Reptilia" (1969–2010), which he conceived, edited, and partly wrote. This compendium, covering the behavior, development, ecology, neurology, physiology, and especially the morphology of reptiles, is one of the monuments of modern herpetological and biological science. Some 169 persons from 21 countries contributed 142 chapters to it. After 42 years, the final volume, a comprehensive list and cross-index to the literature on reptilian biology, appeared in March 2010. It was a great honor when Carl entrusted publication of this classic series to SSAR, which had the privilege to issue the final four volumes.

Carl was also one of the most prolific authors in our field and published more than 700 titles including five books, in addition to the 22 volumes of "Biology of the Reptilia." Among them were a photographic atlas of shark anatomy (1964), his highly popular "Reptiles of the World" (1975, later translated into several other languages including Chinese), and a practical manual on electromyography (1986). Most of his taxonomic papers dealt with the systematics of amphisbaenians (on this topic, from 1957 to 2008, 94 titles including 10 major works), but he also authored numerous titles on the evolutionary basis of adaptation, physiology of snake venom, evolutionary origin of vertebrates, mechanics of hearing and sound production, functional significance of muscle architecture, mechanics of limbless locomotion, and feeding mechanisms in tetrapods.

Despite his long list of titles, his distinguished reputation, and his sometimes gruff demeanor, Carl also had a soft heart and a tendency for pranks. At scientific meetings, he could be very tough (and also usually very helpful) during the Q&A period following a graduate student's presentation when he sometimes displayed a trace of his German accent. He would often then invite the student to go swimming with him (he routinely brought his bathing suit if there was to be a pool or ocean nearby). At SSAR's 25th Anniversary Meeting in Raleigh, North Carolina, Carl was scheduled to present a plenary lecture on amphisbaenians, but wanted instead to talk about functional morphology. He hatched a plot in which Steve Arnold, Paul Hertz, Ray Huey, Ken Miyata, and I were conscripted as co-conspirators. After Carl talked about amphisbaenians for a few minutes, Paul stood up to declare, "With due respect, sir, you've been talking about amphisbaenians for years. Do you really have anything new to say about them?" There was an audible gasp from the audience. One of them leaned over to tell Paul that he had just committed academic suicide! Carl, glaring down at Paul over the top rim of his glasses and seeming quite annoyed, continued on with amphisbaenians. One at a time, the rest of us stood up to voice other comments or complaints. More gasps. Finally, one of us asked him to talk about functional morphology instead, which Carl proceeded to do with feigned resignation. (This event was accurately, but cryptically, reported in *Herpetological Review*, 13:107, 1982: "After repeated interruptions by the audience, the author switched his topic to functional morphology.") After the talk, one senior herpetologist and close friend of Carl's, who was completely taken in and who had wanted to hear about amphisbaenians, dressed me down in no uncertain terms for interrupting the talk. Carl's master plan thus worked perfectly and he was absolutely thrilled to have completely fooled the audience!

Carl Gans was, of course, one of our most distinguished herpetologists. Other biologists, however, tend to think of him as a physiologist, behaviorist, bioengineer, comparative morphologist, or an evolutionary biologist. He also became an active conservationist. Above all, he was a naturalist in the most integrative sense of that old-fashioned, yet refreshingly modern label. And he knew every facet of the lives and evolutionary history of his animals. As he once replied to a newspaper reporter's question, "I can look at a reptile and know if it is happy or not." And Carl Gans could probably do it, too.

Acknowledgments.—Leo Gans kindly filled in the early years of his older brother's life. Several academic colleagues have read over and commented on my manuscript, for which I am most grateful. For help in locating some photos, I thank Robert Dudley, Andrew Gans, and Gregory Schneider.

Carl Gans: The Buffalo Years of 1961–1967

HERB ROSENBERG
Department of Biological Sciences, University of Calgary
Calgary, Alberta T2N 1N4, Canada
e-mail: herb.rosenberg@ucalgary.ca

I met Carl in 1961 when he was 38, clean shaven, unmarried, and had completed just three years at the University of Buffalo (UB) as a faculty member in the Biology Department. He was at UB from 1958–1971 and I worked under him for about half his stay there. I was a "floating" grad student at first and enrolled in Carl's course in evolutionary biology. Two things stand out from that course: 1) an evening field trip in the pouring rain searching for spring peepers in roadside ditches while Carl, replete in suit, tie, and raincoat directed the soaked students in their quest; and 2) enlightening discussions about Lee Dice's work on black and white mice in areas of black lava flows and white sand.

During his days as an assistant professor at the University of Buffalo (1962). Photo by M. Graham Netting; courtesy Kraig Adler.

Somehow I scraped through the course and one night Carl wandered into my grad cubicle, handed me a jar of preserved Emerald Tree Boa heads and two papers by Albright and Nel-

son. He challenged me to see what I could make of the snake's head morphology. Thus started a relationship that lasted some 48 years. Carl was my teacher, PhD advisor, mentor, den mother, role model, friend, and anything else he needed to be for this aspiring but clueless kid from Brooklyn whose knowledge of natural history extended from stickball to the Brooklyn Dodgers. Carl's first grad students were A. A. Alexander, Jim Bonin, Aaron Taub, then there was me, followed by Ed Saiff and H. M. Pandit.

Animals kept in Carl's lab: amphisbaenids, cobras and kraits, and *Bitis gabonica*

Carl's grad students were expected to become familiar with all aspects of herp care hence we served as his animal care technicians in those early, lean years. Carl had a great affinity for amphisbaenids and he focused on biomechanical analyses of their burrowing behavior. Many of these limbless squamates tunnel in sand so it was our job to autoclave vast quantities of sand, set up aquaria filled with sand, keep the sand at the proper humidity, feed the amphisbaenids a variety of food, and observe their feeding behavior. In most cases ingestion takes place after the reptiles draw their food back into the tunnel. We spent many hours staring at mealworms and pinks wriggling on a sandy plane but were rarely rewarded by observations of feeding behavior.

Carl had discovered that he had to attack the taxonomy and relationships of the amphisbanids in order to place his biomechanical observations into a meaningful framework. Part of the lab became a museum-like shipping department as parcels containing preserved specimens arrived from all over the world. We learned how to become curatorial assistants unpacking specimens, checking them off the shipping documents, and setting up jars for future study. We went through enough ethanol to pickle the entire campus but filtered out debris and reused alcohol whenever possible.

What does one do with a preserved amphisbaenid? Measure length of body regions, count annuli, record patterns of head and pre-anal shields, plot characters on geographic grids, take photographs (so we learned every aspect of macrophotography and darkroom technique), and then help Charlene (Carl's technician) prepare the manuscript for publication. Much of this work was later summarized (Gans 2005. Checklist and bibliography of the Amphisbaenia of the world. Bulletin of the American Museum of Natural History 289:1–130).

One of my earliest grad projects with Carl was a histological study in 1967 of serial cross sections that I prepared of everted amphisbaenian hemipenes (to be followed up by an SEM study in 1991). I obtained specimens to be sectioned by rummaging through the jars of preserved specimens in Carl's collection. One day Carl called me into his office and began to tear a strip off my hide….I had snipped off the everted hemipenis of a type specimen from the MCZ! Carl phoned Dr. Williams and the tempest was calmed when Ernest suggested that when the type is returned we include the slide box of serial sections as well. This is one of the very few times I saw Carl lose his temper. So somewhere on a shelf of the herp collection at the MCZ, hidden by jars of preserved whole specimens, sits a little box of slides made by yours truly.

At least amphisbaenids are not venomous! Carl focused on ophidian envenomation as an offshoot of his interest in reptilian feeding mechanisms. Aaron Taub worked on the structure and function of Duvernoy's gland, Elazar Kochva from Tel Aviv University spent a long sabbatical with Carl furthering his investigations of viperid venom glands, the late Bill Elliott fractionated and analyzed fresh venom, and I chipped in with a thesis on venom glands of elapids and sea snakes.

Thus Carl began to house all sorts of kraits, cobras, and vipers in his "animal room." Why is it that shipments of live kraits from Thailand always arrive in the middle of the night? Carl and grad students would drive to the airport with snake sticks, Pilstrom tongs, cages, bags, etc. We always offered to open the boxes for customs but somehow they always declined our offer. That's when my true colors began to show. It's one thing to stare at the mealworms in an amphisbaenid's sandy world but it's something else to clean the cage of a cobra or the fattest Gaboon Viper I ever saw. Carl never hesitated to keep these dangerous reptiles but I must say he was very cautious. Thus, he would never order live specimens unless he had a supply of the proper antivenin in his fridge. Carl developed an elaborate protocol with campus security so that each time we had to take dangerous specimens out of their cages, the campus police had to sit in his lab (while the red light was on) prepared to do a hospital run with the "victim" and a stock of antivenin. As far as I know, there never was a mad dash to the Buffalo General but there were several entertaining practice runs.

Formal portrait with Kyoko A. (Mabel) Gans, three years after their marriage and during his period at the University of Buffalo (December 1964). Photo courtesy Andrew Gans.

Caged animals somehow manage to escape. Venomous snakes were not a problem as they were all secured in padlocked cages designed by Carl. I will never forget one Saturday night when some arboreal lizard managed to gain its freedom and Carl was immediately notified as per his instructions. Carl and Mabel arrived dressed to the nines for a night at the theatre. Carl slipped out of his jacket and suspenders, then stepped out of his trousers and took off after the lizard in his boxer shorts, shirt, and tie. Mabel and I averted our gaze not so much out of modesty but to prevent bursting out in laughter. Carl caught the lizard, dressed, and headed off for a night on the town with Mabel.

Work habits in the Gans lab: time, technology, and writing

There is Eastern Standard Time and there was Gans time. Carl had a very different biological clock. He would usually arrive at the lab in the mid-afternoon and work till early morning of the next day. Of course his grad students were expected to be in the lab while he was there but they often had to teach an undergrad lab at 8 AM the next morning! Several times a week Carl would treat us to pizza at 2 AM; he would return to work and we would stagger home with our sleep impeded by a gastrolith of spicy, rubbery cheese and dense dough. Those were our good old days!

Carl would arrive at his office, spend time with phone messages, incoming mail, signing letters that had been typed by his secretary (Gloria) during the morning, and checking on grad students. Then he would settle down to work and revise manuscripts. Each manuscript was kept in a three-ring binder with the most recent version on top. Carl would read and "mark up" the manuscript in a very distinct, almost illegible scrawl for his secretary to retype the next morning. Thus, a manuscript was gone over again and again and eventually honed into a finished product to be submitted for publication. Grad students read the "final" version and were rewarded for any typos we might spot (they were few and far between). When the proofs were sent to Carl we would team up and

the grad student would read every word, punctuation mark, and number (think of all those columns of scale counts!) while Carl corrected the proof. Talk about hands-on learning. We followed the same process as we wrote our theses and prepared them for publication. Carl always acknowledged our help in print at the beginning of each publication we had been involved with.

One pillar of Carl's reputation rightly rests on the huge number of his publications (those written alone and those co-authored with colleagues). He had to rely on the technology of the day and would have been very much more productive if his entire career had been supported by computer-based word processing. When I arrived in Buffalo, Carl was progressing through a wide variety of voice recorders that he would use to dictate letters, memos, and first drafts of the several manuscripts he was working on. He always had a pocket- sized recorder with him to dictate memos to himself, students, et al. and these were constantly being replaced by newer models. Remember, his handwriting was not easy to decipher so his secretary played back his words through earphones while she typed the transcription. Carl would read through what was typed, edit the text, mark up the pages, and return them to the secretary for re-typing. This process would be repeated again and again with total retyping often being required! When I first arrived there was a manual office typewriter, then there was an IBM Selectric, followed by an IBM Magcard Selectric that stored information on magnetic cards, and eventually word processing (after I had moved on). When Carl finished with one typewriter, he would place it in the lab for his students to use; we were always one step behind in IT.

Carl was very innovative when he turned to biomechanical, physiological, and functional morphological investigations. Even before that he constantly sought to improve his efficiency in the lab. Thus, he invented (along with Bill Tanski) a foot pedal device (manufactured by Gomco in Buffalo) that allowed the operator to focus a dissecting microscope and leave both hands free to hold dissecting instruments (U.S. Patent Office 3,350,977). My role in this was to be the male model, sit at the lab bench, and pretend to be dissecting a snakehead for the sake of the publicity photos. While I was decked out in a tie and starched lab coat, my feet were clad in worn-out basketball sneakers. Imagine my surprise when the ad that appeared in *Bioscience* showed me wearing well-polished brogues that had been airbrushed over the sneakers (and this before the advent of Photoshop)! Later, Carl added a second foot pedal that activated a tape recorder so he could dissect with both hands, continue to keep the field of work in focus, and record his observations on tape all at the same time.

Carl became a great proponent of electromyography (EMG) as an analytical tool for functional studies. He spent a sabbatical in the lab of George Hughes learning the basics of EMG and was sure that if Hughes could record electrical activity from branchial muscles of sharks in tanks of water, he could certainly record from muscles used by tortoises in pulmonary ventilation on dry land. Thus started a prolonged series of EMG studies in a great diversity of vertebrates that focused on feeding, locomotion, ventilation of lungs, and other topics. Carl became involved with electrodes, amplifiers, oscilloscopes, all sorts of recording devices, and high-speed movie cameras (in some cases using strobe lights designed for aircraft!). Most of these technical accomplishments were reported in Loeb and Gans (1986. Electromyography for Experimentalists. The University of Chicago Press, Chicago, Illinois. 373 pp.).

Surrounded by the Central Dogma

The molecular biology bandwagon started to roll in the Biology Department at Buffalo in the early1960s. Suddenly, new faculty members arrived on the scene, vast areas of "open space" were occupied (goodbye to graduate cubicles), and the hum of ultracentrifuges filled the air. The nature of seminar programs was altered and traditional graduate pathways were complemented by those that went from DNA to RNA to protein synthesis. Carl more than held his own during this inundation but tended to spend more time with departmental politics. Friendly competition prevailed on the softball field as well as indoors. When Carl invited Professor Romer to deliver a departmental seminar, he requested his grad students to make the arrangements for coffee and cookies. Here was a chance for us to gain on the molecular types; no Oreo cookies for us. We set up a grand spread of bagels, lox, and cream cheese much to Carl's (and the ever-hungry grad students') delight. What a memorable event that seminar was!

Carl's libraries: in the lab, at home

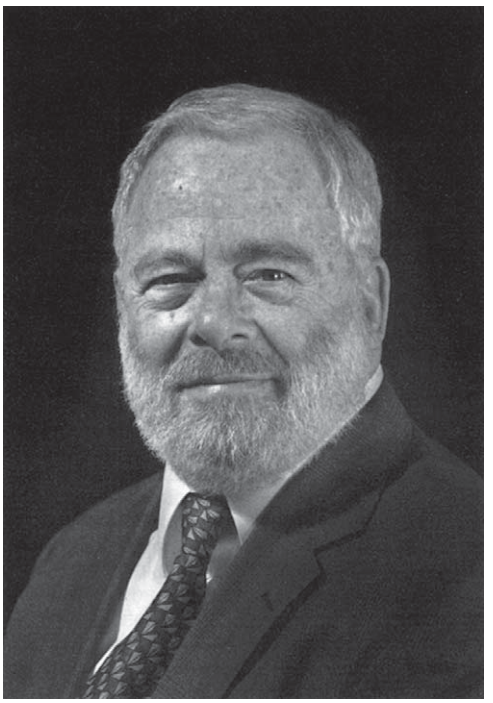
Carl developed one library in his lab and one at home. The scientific library grew as a result of an extensive network of reprint exchanges with friends and colleagues around the world (*Current Contents* was less than five years old then). He also purchased important volumes from book dealers in North America and Europe. Whole sets of reprints had to be located and ordered whenever a new project took shape. The library was organized in a somewhat confusing but logical (to Carl) fashion so reprints could be retrieved from their boxes. First of all there was a geographical level of organization, set up by continent and then country; then the North American reprints were set up alphabetically by journal title; but there were also a variety of special sections that I was never too sure about. Of course in those lean times grad students would be required to learn about the world's literature by refiling reprints. We tried our best but not to worry, periodically we would "go through the collection" with Carl looking on to set things straight.

The collection at home consisted of cowboy novels, detective stories, science fiction, and whatever Carl happened to enjoy. Steel bookshelves in the attic of his Buffalo (and later Ann Arbor) home were lined with hundreds upon hundreds of paperbacks. Students had access to this collection as well but we never had to reshelve these books.

Barbeques galore

Carl was the consummate host and he loved his beef. Thus for summer, outdoor entertaining he typically fired up the barbecue in his backyard while Mabel produced large bowls of salad (that Carl barely glanced at). Grad students, undergrads, technicians, secretaries, colleagues, and visiting firemen were always invited. The beef was plentiful but almost as important Carl would always introduce the students to visiting zoologists from the famous to the infamous and inform them of our research programs. Just a few who stand out were the Belgian herpetologist G. F. de Witte, the Swiss neuroanatomist Werner Stingelin (who spent a sabbatical with Carl), the morphologist from Brooklyn, Paul Maderson, the morphologist Tom Parsons, the Israeli zoologist Elazar Kochva (who spent a prolonged sabbatical and helped mentor me in venom gland architecture), the Dutch physiologist Hank DeJongh (also spent a sabbatical in Buffalo), Toby and Sandra Gaunt, Carl's mother, and of course, A. S. Romer and E. E. Williams. At times it seemed as if there was a steady stream of visitors to Carl's lab and then backyard.

Conclusion



Thus, Carl's grad students received a very full regime of preparation for the real world. If Carl took you under his wing it meant that he took a deep interest in all facets of your education. Carl required me to complete a course in Botany, a full-year course in Human Anatomy in the UB medical school, a summer field course with OTS in Costa Rica (1965), and a post doc in chemical communication of insects at Cornell University with Carl's friend Tom Eisner (who else would accept me?).

Carl taught me many things beyond zoology. He was generous when it came to supporting various charitable organizations. He went out of his way to invite students, post docs, and faculty members to a stint in his lab from all over the globe knowing that their experience would further their careers once they returned home. He gave back to the profession by serving as the editor of the *Journal of Morphology* for 25 years. Carl also went out of his way to help authors rewrite and polish manuscripts

they submitted to the 21 volumes of "Biology of the Reptilia" that he co-edited and edited. Sure, he was demanding and had high standards but we were the ones who gained and eventually passed on the traditions to our students. Thank you, Carl.

Carl Gans: The Ann Arbor Years

R. GLENN NORTHCUTT
Graduate Program in Neurosciences, University of California, San Diego
La Jolla, California 92093-0662, USA
e-mail: rgnorthcutt@ucsd.edu

Formal portrait as Professor of Zoology at the University of Michigan (ca. 1994). Photo courtesy of the University of Michigan and Greg Schneider.

In 1971, at age 48, Carl moved to the University of Michigan in Ann Arbor as Chair of the Department of Zoology. He was near the peak of his scientific powers then and for the next 27 years, during which he continued to edit the *Journal of Morphology* and "Biology of the Reptilia" in Ann Arbor. During his first year as Chair, Carl paved the way for my own move to UM, where we taught, collaborated, ate and drank together, often with our wives, for the next 14 years. Our one-semester course in Comparative Vertebrate Anatomy usually involved around 100 students and consisted of four lectures and six hours of laboratory each week. Carl and I usually divided the lectures equally, and after each class we routinely repaired to a local pastry shop to critique the day's efforts, making sure that our discussion ended on a sweet note. Our papers together on the origin of vertebrates literally grew out of our reorganization of the Comparative Vertebrate Anatomy course at Michigan.

During his first four years in Ann Arbor, Carl provided strong leadership for the department at a particularly difficult time. Higher administrative officials were forcing a merger between Botany and Zoology, an action highly unpopular with both departments. The effects of this imposed merger were exacerbated by a downturn in Michigan's economy, which could have resulted in the loss of the university's non-tenured faculty in many departments. To Carl's great credit, he convinced the tenured members of his faculty to forgo raises in order to keep the entire faculty intact. His principles of fairness continued to be in evidence, as he was very active in correcting salary inequalities for women and minorities, at a time when the justice of such parity was anything but assumed.

While in Ann Arbor, Carl maintained an incredibly active laboratory, including graduate students, postdoctoral fellows, and an endless number of international visitors. Carl was a gruff colleague, however, and—although he was basically kind—he could be remarkably caustic, and he was not an ideal mentor for anyone with a hide less thick than a crocodilian's. I first met Carl while I was a graduate student with Hobart Smith at the University of Illinois. Hobart introduced us, then left to attend to other duties. Carl grilled me for at least 30 minutes on my research, albeit offering some good advice in the process. When he finally stopped, I asked, "And what are you working on now, Dr. Gans?", and Carl replied, "Everything," before leaving the room. Despite being somewhat put off by this reply—which I later decided was not totally inaccurate—I thus began my friendship with Carl Gans.

In addition to his scientific passions—namely morphology, biomechanics, and the biology of amphibians and reptiles—Carl had a passion for life in general, including food, wine, the arts, and travel. He did a great deal of the last in the course of his research, and he was an acute observer of political systems in the countries he visited—such as Australia, India, Sri Lanka—reading extensively on their social systems as well as their fauna. It was also rather a badge of honor with him to have endured fairly primitive field conditions in pursuit of his science. He was intensely fond of numerable art forms, everything from grand opera and early Japanese erotica to "The Cremation of Sam McGee," which he could often be persuaded to recite from memory after the wine had been flowing freely. After dinners at Mary Sue's and my home, he also sometimes led other guests in a rousing chorus of Gilbert and Sullivan songs. Carl was an exhaustive reader, virtually inhaling serious literature and hard-boiled detective stories with equal gusto. As a movie fan, his tastes were similarly catholic. He was particularly fond of Clint Eastwood's "Dirty Harry," who became his alter ego, but he appreciated foreign films and "serious" films. He also once persuaded me to accompany him to a showing of "Deep Throat," after which he remarked, "Oh well, there are only so many orifices in the human body." Always the morphologist, Carl was.

His wife Mabel (Kyoko) shared many of his passions, including travel, though not the deprivations of field work. She was confidant, research assistant, social secretary, and hostess. Regardless of whatever professional or personal pressures the two were experiencing, they were unfailingly gracious hosts, and always demonstrated love and support for one another. Scientifically and personally, Carl and Mabel had a profound effect upon Mary Sue and me, as well as on other academic couples who had the good fortune to interact with them for an extended period of time.

During his years in Ann Arbor, Carl was not always easy, as a colleague or as a friend, but what stands out in my mind is the respect and affection I had for him then and now.

Reminiscences of Carl Gans

AARON M. BAUER
Department of Biology, Villanova University
Villanova, Pennsylvania 19085, USA
e-mail: aaron.bauer@villanova.edu

Although I never attended a school where Carl Gans taught and cannot claim to have been particularly close to him, he was an important influence on my personal and professional development, as he was for many other herpetologists. Perhaps appropriately, I learned of his death after a week of collecting in the Caprivi Strip of Namibia, which yielded a diversity of organisms that played a role in Carl's career, among them the egg-eating snake *Dasypeltis*—the subject of his doctoral dissertation, and several species of amphisbaenians—the organisms most intensely studied by him.

In the spring of 1980 I was an 18-year-old freshman at Michigan State University and, after taking Comparative Vertebrate Anatomy in the winter quarter, signed up for a graduate seminar in "advanced morphology" taught by Jim Edwards. The course included some lectures and stu-

dent-led discussions of relevant primary literature in vertebrate morphology. Carl's "Biomechanics" was the course text. Each student selected a prominent morphologist and was responsible for selecting and leading the discussion on papers by that author. As a budding herpetologist, I chose Carl Gans, whose work on locomotion in amphisbaenians—a group then practically unknown to me—I found fascinating. The course also featured guest lectures by visiting morphologists, one of whom was Carl. Because of my special interest in reptile morphology and because I was "responsible" for Carl's papers in the course, I was invited to dinner with Carl at the Kellogg Center, just across from my dorm. Although I was clearly out of my depth, I was thrilled to have the opportunity to talk to the great Professor Gans, who engaged me in conversation as if my opinion actually mattered and thus cemented my intention to pursue research in reptile morphology.

I next encountered Carl at my first SSAR meeting (Salt Lake City in 1983). I was in a morphology session, back-to-back with a number of my fellow Berkeley graduate students. Carl was in the audience and all the students in the session were on edge, hoping that he didn't find fault with their presentations and turn the question period into an uncomfortable grilling. For one of the speakers before me it was a worst case scenario. When questions opened, Carl stood up and began by saying "Your premise is fundamentally flawed …." Somehow, seeing that my colleague survived this settled my own nerves and 15 minutes later I gave my first scientific presentation with confidence. Carl's questions were direct and generally on the money and his criticisms were typically valid, revealing either real flaws or inadequacies in presentation that detracted from the arguments presented. Although it could be intimidating to face Carl under such circumstances, his criticisms were typically fair, and his negative opinions, especially in the case of students, were usually aimed at the work and not the individual. However, Carl did make enemies, and close association with those on his bad side could strain relations with him. Carl enjoyed the fact that he was held in awe (or fear) by students (and many more senior colleagues) and that he was taken deadly seriously by nearly everyone. In reality, despite the gruff exterior, he was fond of playing subtle jokes that would be signaled by winks and nods to those in the know.

At the SSAR annual meeting in 1984, Carl, then president of SSAR, had donated several items for the SSAR auction. One was Da Silva's "Snakes of Sri Lanka," which had been published shortly before. The work was not generally available outside Sri Lanka and Carl had picked it up on one of his trips there. For bibliophiles the book was a rare prize and there was spirited bidding. Ultimately I was one of three bidders left when the price exceeded $100 (then more than 10% of my monthly TA salary and more than half my rent). My competitors both had "real" jobs and I eventually dropped out at about $150. Later in the evening Carl came up to me and said "Thanks for driving the bidding up. I'll send you one next week." He did and through the years occasionally remembered my interest and picked up extra copies of obscure titles for me.

After I became gainfully employed, Carl and I began an abortive project on locomotion in limbless skinks of the genus *Acontias*. Having just returned from South Africa with live specimens, I flew to Detroit in the dead of winter and stayed with Carl in Ann Arbor, "running" the lizards on pegboards in his lab and writing in tandem, sitting with Carl at his computer while he typed. Carl's schedule, rising late and working until the wee hours of the morning, was more or less six hours phase-shifted from my own and I could barely stay awake as a new set of animals was introduced to the pegboards at 3 AM. This was exacerbated by an unfortunately timed bout of recurrent malaria. Carl barely noticed that I was sweating and shivering in his single-minded pursuit of the project. However, back at home, he immediately switched modes and became "daddy" to his dog P.C., who brought out his softer side.

Although I would never dare to compare my accomplishments to Carl's, I did end up following in his footsteps in terms of research venues and for many years I have passed in Carl's wake in southern Africa, India, Sri Lanka, Australia, Eastern Europe, and elsewhere. In nearly every place I have visited people know Carl, many personally from his own extensive travels, but certainly at least by reputation. Indeed, Carl was probably the most well-known herpetologist in the world at large for a period of 20 years from about 1970 to 1990. As Carl's health declined and his travels decreased, my foreign colleagues would always ask about him. Many were profoundly affected by him and most considered it a genuine privilege that they were able to interact with him, both personally and professionally. A visit from Carl Gans brought prestige to any researcher or institute.

Carl Gans and field crew in 1978 in the Pilbara region of Western Australia where, on their way back to Perth, the party stopped to see some aboriginal rock carvings at Woodstock Station. Among those present are Gans (crouching) with Harold Cogger on his left (in shorts), Hubert Saint Girons on his right (with cap), and Donald Bradshaw at the wheel of the vehicle Photo courtesy of Donald Bradshaw.

Carl Gans was larger than life. His domination of diverse biological disciplines was unparalleled in the late 20th century. That his was both the first and last word on so many topics is attested to by his bibliography, which lists a score of "prefaces" and "concluding remarks." I only had the opportunity, along with Rainer Günther, to co-author one paper with Carl, in 1997, on the amphisbaenian types in the Berlin Museum. However, my favorite of his 600+ works, or at least my favorite title, is a 1978 paper from *American Zoologist*—"All animals are interesting!" As reflected by his life's work, Carl certainly believed this and helped the rest of us believe it too.

Carl Gans: The Austin Years 1997–2009

CHRISTOPHER J. BELL
Department of Geological Sciences, 1 University Station – C1100
The University of Texas at Austin
Austin, Texas 78712, USA
e-mail: cjbell@mail.utexas.edu

Carl Gans and his wife Mabel retired to Austin, Texas in 1997. Serendipitously, that was the same year I arrived in Austin, but they beat me here by several months. I had maintained a fruitful and entertaining correspondence with Carl for many years, beginning in 1993 with the publication of my first papers on fossil lizards. I sent copies of those papers, as a 'calling card' of sorts, to many people who had published on fossil reptiles, introducing myself and my shared interest in that topic. At the end of the accompanying (and, in retrospect, startlingly naive) cover letter, I included a brief request for copies of all papers the recipient might still have available for distribution. Carl was one of the recipients of that letter. Soon after, I received a reply from him indicating that he was somewhat taken aback by my open-ended request for reprints, but had decided to send me copies of all titles he still had on hand. Even now I cringe a bit when I recall the day I received a large box containing

hundreds of monographs and reprints authored and co-authored by Carl. He apparently was amused by both my initial request and the humble 'thank you' letter that followed, and we continued to exchange letters and publications for several years, but never actually met until I arrived in Austin. A few months after settling here I answered my telephone one afternoon and heard a deep and somewhat gruff voice admonishing me for not having been in contact... "You haven't called me, so I thought I'd better call you." I had no idea to whom I was listening until he identified himself as Carl Gans. He proposed dinner, I accepted, and we met in person for the first time.

Those who knew Carl in his days at the University of Michigan have made clear to me that I knew him in a different way than they did. The descriptions I would provide of my interactions with Carl seemed impossible to some of them, as if I were describing a second person of the same name. A few hints of the sobering interactions that sometimes arose between Carl and graduate students are found in the reflections that accompany my own in this compilation; the rumor mill carries many other stories. Carl even implicated himself one night during dinner with my wife and me, when he joked "I used to eat graduate students for lunch." I knew Carl as a serious scientist, critical thinker, meticulous editor, avid reader, and bibliophile, but also as a genial colleague with a subtle sense of humor who enjoyed a good chuckle, and gave and accepted lighthearted teasing with equal delight. I have no terror stories, no squirming moments of discomfiture as my ideas were dissected and ego bruised in a clash with Carl. Instead, I always received considered advice, support for my endeavors, and a subtle but persistent encouragement toward higher standards in everything. Carl shared his time and expertise freely, along with a seemingly endless supply of reminiscences and anecdotes about his collections, field trips, colleagues from around the world, and parties at the annual herp meetings.

Carl's retirement was not a retreat from science, nor from active engagement with students and his colleagues. He enjoyed acquainting himself with the herpetological fauna of Texas, and took particular delight in announcing his Austin home address on Slow Turtle Cove. He moved here at the invitation of Robert Dudley, a collaborator and colleague who was then on the faculty in the Department of Integrative Biology at The University of Texas at Austin. Carl held the position of Adjunct Professor and maintained a research laboratory in that department, served as a member of PhD student committees, and participated as guest lecturer or discussant in several courses in the departments of Integrative Biology and Geological Sciences. His research activities were truncated shortly after arriving in Austin, when Mabel was diagnosed with cancer. Following her death in 1999, Carl refocused his attention on his scientific and literary pursuits with emphasis on three major projects in herpetology. One was an intensified effort to obtain from authors the final manuscripts for a new volume in the "Biology of the Reptilia" series, and to see those manuscripts through the review and revision process (these were eventually published as volumes 20 and 21 in 2008). The second project was an ongoing collaboration with Ricardo (Ueso) Montero on the cranial osteology and skeletal development of amphisbaenians (published in 1999 and 2008). The third was compiling and editing an updated checklist of the Amphisbaenia of the world, accompanied by an extensive bibliography on the group (2005).

He regularly hired undergraduate and graduate students to help him with research tasks and to work in his libraries. One of those libraries was an extensive collection of paperback novels that were housed in a loft above his master bedroom. His more expansive scientific research library filled a three-car garage and represented an intensely personal collection, incorporating books from his early career as an engineer, and reflecting his broad interests in natural history. He maintained subscriptions to no fewer than 85 serial publications, several of which are rarely seen in personal collections. Carl had a particular fondness for ferreting out what others have called 'obscure' literature, but he was adamant in his denial of the existence of such a category. In his view literature simply exists, and it is our responsibility to seek it out and cite it where relevant. He had an amazing ability to remember exactly what was in his library, as well as how to find it. The latter was no small accomplishment in a library the size of his. Apart from special topics (e.g., mimicry, conference abstract volumes, functional morphology), he generally filed his books, monographs, and reprints geographically. Usually the geographical referent was the topic, but sometimes he filed based on the location of the publisher. For example, Duellman's monograph on the equatorial herpetofauna of Amazonian Ecuador might be filed in South America, or in Kansas, depending on how Carl thought about it at the time he obtained and shelved it. Until you learned to think like he did about the organization, finding particular items could be a challenge.

Carl suffered a debilitating stroke in late January, 2001. After a short period in hospital he returned home, but was confined to a wheelchair. He and his brother arranged for some renovations to his house after the stroke, but among other inconveniences he was no longer able to enter the stacks in his research library. The fixed shelving was spaced to accommodate a maximum of printed material, not the width of a wheelchair. After his return from the hospital, my visits with Carl always included some time in his library, filing newly-received materials and pulling titles that Carl needed or wanted to see as he continued the increasingly frustrating effort to maintain his research activities.

In the years following his stroke a major priority for Carl was making arrangements for the disposition of his remaining collections. Prior to his retirement, most of his skeletal and alcoholic specimens were deposited in the Museum of Comparative Zoology at Harvard University and the Carnegie Museum of Natural History in Pittsburgh. He retained his amphisbaenian and uropeltid snake collections until it became clear that he would no longer be able effectively to work with those specimens. Although a small collection of dry skeletal specimens was donated to the Vertebrate Paleontology Laboratory at UT Austin, the majority of the uropeltid snakes ultimately were deposited at the California Academy of Sciences in San Francisco, and the amphisbaenians went to the Field Museum of Natural History in Chicago.

As far as I know, Carl recognized only two 'subcollections' within his scientific library, constituting materials that were filed and housed independently from the main body of his collection. The first was his lancelet collection, the second his reprints and monographs pertaining to amphisbaenians. His attempt to survey the extensive literature on lancelets included gathering physical copies of the majority of the 2696 titles cited in the published 'bibliography of the lancelets' (1999). That collection was deposited at the Scripps Institute of Oceanography in La Jolla, California. A substantial portion of his literature on the Amphisbaenia was sent to Maureen Kearney at approximately the same time that his specimens went to the Field Museum. The remainder of his library, along with 13 filing cabinets containing his scientific correspondence, was deposited at the Ben Gurion University of the Negev, in Midreshet Ben-Gurion, in the Negev Desert in Israel.

Although he struggled with declining health in his later years in Austin, Carl always enjoyed visits from colleagues and former students, and drew satisfaction from the simple pleasures of a fully retired lifestyle. He especially enjoyed his contact with graduate students, hearing about their projects and offering advice or suggestions for interesting questions or problems. He enjoyed and appreciated letters from other scientists who wrote with data or questions following up on one of Carl's earlier publications. He was especially gratified when he heard the news in 2008 that salamanders had been discovered once again in the parks on Manhattan Island in New York City (see Kraig Adler's account above).

Carl was a connoisseur of fine coffees and chocolates. He pursued these with increasing enjoyment after his stroke, and drew greater satisfaction from the pursuit of favored comestibles as his research activities waned. He maintained an impressive mental list of 'favorite' restaurants in Austin, as well as a slightly more select register of appropriate venues for the consumption of dessert. An evening meal with Carl often was a multi-hour event, and could involve stops at as many as three establishments. Such evenings were always a welcome opportunity for Carl to

enjoy good company, good food, and good conversation. He died on 30 November 2009, and is buried in the Cook-Walden Jewish Cemetery in Pflugerville, Texas.

Amphibian populations are declining around the world (Wake 1991). Of the 6433 amphibians species (Frost 2009), close to 500 species are considered endangered (Stuart et al. 2008). Thirty-eight amphibian species have been declared extinct (IUCN 2008). For Costa Rica, the magnitude of amphibian declines has been so severe that three endemic species were declared extinct: the famous Golden Toad, *Incilius periglenes*, in 2002 (IUCN 2003), and both *I. holdridgei* and *Craugastor escoces* (Craugastoridae) in 2007 (IUCN 2008). The reduced geographic range of these species, their conspicuity, and the substantial search effort invested in areas where they previously were abundant justified categorizing these species as Extinct (IUCN 2008). These disappearances have been attributed to different causes, including climate change (Pounds 1997, 2001) and emergent diseases such as chytridiomycosis (Lips et al. 2006), or the synergistic effect between these two agents (Pounds et al. 2006).

A species is considered extinct when, as defined by IUCN (2001), there is no reasonable doubt that the last specimen has died. Difficulties with this designation may arise for secretive species or when the reproductive behavior of the species changes in relation with the reduction in population density (Mattsson et al. 2008). For example, explosive reproduction is a strategy to reduce the individual predation rate and increase the attraction of females (Duellman and Trueb 1994). When such species decrease in numbers, it is common to assume they are headed to extinction, but it is possible that they use an alternative reproductive behavior. The Costa Rican highland toads represent a classic example of these problems. Most of them are subterranean, emerge during explosive breeding events, and produce little to no audible vocalization. The need to form aggregations during reproduction may

cause difficulties to mate when population densities are reduced (Novak and Robinson 1975).

In 2006, Costa Rican herpetologists created a national strategy for the conservation of amphibians (Bolaños et al. 2007). This strategy included *in situ* and *ex situ* conservation, basic and applied research, and public education. Amphibian species that experienced the most drastic declines were recommended for *ex situ* conservation actions (Bolaños et al. 2008). A fundamental component of the national conservation strategy is increasing fieldwork to locate remaining populations of declining species. Amphibian species with relict populations represent an opportunity to test hypotheses concerning the causes of declines and ecological and evolutionary responses.

Here we report the recent rediscovery of *Incilius holdridgei* in a young secondary forest of Alto El Roble in the Cordillera Volcánica Central of Costa Rica. *Incilius holdridgei* (Taylor 1952) was described based on a single specimen collected at Finca Georgina, on the west slope of Volcán Barva at 2280 m (Savage 1974). Subsequently, other substantial populations were found on the southern and eastern slopes of the same volcano, with known localities including Sacramento (G. Barrantes, pers. comm.), Cerro Chompipe, and Alto El Roble (Novak and Robinson 1975). This species used to be very abundant at the last locality (J. Savage, pers. comm.), and their ecology and reproduction was described by Novak and Robinson (1975). The discovery of *I. holdridgei* represents the first in 25 years and removes the species from the Extinct category (IUCN 2008).

Materials and Methods.—On 1 May 2008, during a field trip by students in the herpetology course from the Universidad Nacional de Costa Rica, eight juvenile bufonids were observed in Alto El Roble (10.0946°N, 84.0624°W, 1900 m elev.) by JA. All juveniles were found during the day in leaf litter, or among rushes and grasses. As only two species of bufonids had been reported in Alto El Roble, the extinct *Incilius holdridgei* and the secretive *Crepidophryne epiotica* (Savage 2002), it should not have been difficult to establish the identity of these specimens. However, the specimens were only photographed by one of the students and the quality of the pictures was not suitable to allow identification.

From April to May, 2009, we visited the same area four additional times to conduct diurnal and nocturnal surveys to collect specimens to resolve the species identification. We searched for eggs and tadpoles in the pond located along the 2 km stretch of road between Alto El Roble and Río Las Vueltas (10.0878°N, 84.0739°W, 2100 m elev.). We collected several tadpoles to determine species; tadpoles were later returned to the same pond. At the small trail in Alto El Roble where the juvenile toads had been observed in 2008, we conducted an exhaustive sampling of the forest floor during the first survey. We inspected the leaf litter, logs and rocks in an area of 2000 m^2. Each amphibian observed was collected, identified in the field, and returned to the forest. Some specimens were collecting as vouchers and were deposited in the Herpetological collections of the Museo de Zoología of the Universidad de Costa Rica. Other survey methods employed by us included 300 m visual encounter transects (Crump and Scott 1994) in the forest. We also surveyed ponds for presence of eggs and tadpoles.

Results.—Contrary to the patterns described in previous decades when pastures and open areas dominated Alto El Roble (Novak and Robinson 1975), today, the area consists of secondary forest

COLOR REPRODUCTION SUPPORTED BY THE THOMAS BEAUVAIS FUND

FIG. 1. Adult male *Incilius hodridgei* (UCR 20657), found in Alto El Roble, Costa Rica, 25 years after the last observation in the 1980s. Photograph by José Salazar.

dominated by oak trees (*Quercus* spp.) with dense undergrowth. Water sources near the site include areas of slow drainage and shallow puddles. We also found temporary ponds in the same area in which *Incilius holdridgei* was observed in the 1970s (Novak and Robinson 1975); however, we found only the tree frog *Isthmohyla pseudopuma* in these ponds (egg masses, tadpoles, and adults).

One adult male (UCR 20671), clearly identified as *Incilius holdridgei* (Fig. 1), was found on the night of 24 April 2009 at 2149 h, inactive in the leaf litter, at a location only 5 m away from the site where the juveniles were seen in 2008. During surveys in the forest, both juveniles and adults of *I. holdridgei* were observed in an abandoned trail cover with bushes and grasses. We did not observe eggs, amplexus, or male aggregation in the small ponds surveyed. On the morning of 25 April 2009, one adult male was found 2 cm below the soil surface, possibly indicating that prior to the reproductive season, individuals of this species may remain in underground refugia.

On 3, 9, and 17 May 2009, two juveniles (15 mm SVL) and three adults (34 mm, 31 mm, and 31mm SVL) were observed by JA at the same locality. We have no records of mating thus far, but the fact that we have found juveniles in both years indicates recent reproductive activity. We have yet to see the large aggregations described in the 1970s (Novak and Robinson 1975).

Discussion.—The rediscovery of *Incilius holdridgei* requires reconsideration of this species to the current IUCN category Extinct (IUCN 2008). We suggest reassigning *I. holdridgei* to the Critically Endangered category (IUCN 2001). Also, the rediscovery of *I. holdridgei* indicates the necessity to do more fieldwork to encounter other declined species in Costa Rica. As part of these efforts, we are working on geographic models that combine the potential distributions of the most severely declined species, the localities of the relict populations, and the climatic conditions in these areas. Such analysis should help to define areas with higher probabilities for locating endangered species and facilitate the selection of areas to survey.

This finding also has implications in the discussion of the

emerging diseases hypothesis and the amphibian conservation strategies. Chytridiomycosis has been considered a devastating disease capable of extirpating amphibian populations of sensitive species over large areas (Lips et al. 2006). However, our discovery of a population of *Incilius holdridgei* in a region with well documented chytridiomycosis (Puschendorf et al. 2006), allows a test of its vulnerability to this disease. The survival of some members of this species creates opportunities for amphibian conservation through *ex situ* reproduction and reintroduction programs. However, this discovery forces us to reconsider conservation efforts. Traditionally, conservation has been relegated to *ex situ* efforts or *in situ*-based efforts in protected areas. We believe that the role of recently abandoned agriculture and livestock areas, as in the case of this population of *I. holdridgei*, should be more closely evaluated together with the traditional protected areas, as it appears to have been critical to this species survival. A continuous field monitoring program is needed to quantify the population status of this species, including the identification of potential breeding sites and reproductive aggregations.

In recent years, the Alto El Roble area has become a tourist destination that receives thousands of persons per year, mainly during the weekends. Most of them travel by foot but the use of cars, quadracycles, and mountain bikes is not rare. The breeding sites for treefrogs, ranids, and bufonids in Alto El Roble are the small ponds around the principal road (Novak and Robinson 1975), most of them exposed to tourist traffic. The recovery of the *Incilius holdridgei* population in Alto El Roble could be difficult under an increasing trend in tourist activity with the potential destruction of critical breeding sites.

Acknowledgments.—Research was conducted during the preliminary visits to establish the Master Science thesis project for the senior author. Collecting permits for fieldwork was provided by the Ministerio del Ambiente, Energía y Telecomunicaciones, permit 152-2009-SINAC to GC. We thank Robert Puschendorf, Andrew Crawford, Kris Kaiser, Paul Hanson, William Bussing, Larry David Wilson, Andreas Hertz, Joe Mendelson, and Gunther Köhler for comments that improved the manuscript. Special thanks to José Salazar for the photograph of the voucher specimen of *Incilius holdridgei*.

Toe-Twitching During Feeding in the Australian Myobatrachid Frog, *Pseudophryne corroboree*

A number of anuran species exhibit behaviors involving pedal movements, which have been suggested to either lure or promote activity in prey animals. A recent review has summarized this behavior from 13 taxa within seven anuran families (Sloggett and Zeilstra 2008). In some larger species that feed primarily on vertebrate prey, the movement of toes as a feeding response appears to be aimed at attracting prey (Bertoluci 2002; Hagman and Shine 2008; Murphy 1976; Radcliffe et al. 1986). This behavior is most elaborate in the South American horned frogs (*Ceratophrys* spp.), where toes from the rear foot are raised and waved in a luring fashion in front of the frog's mouth (Murphy 1976). In smaller species that feed predominantly on small invertebrates, toe-twitching may often occur during feeding (Sloggett and Zeilstra 2008). Sloggett and Zeilstra (2008) proposed that toe-twitching in these instances may provide a vibrational stimulus to ensure that the intended prey continues to move and be detected.

Here we describe toe-twitching behavior as a component of feeding behavior in an Australian myobatrachid frog, the terrestrial Southern Corroboree Frog (*Pseudophryne corroboree*). *Pseudophryne corroboree* is a critically endangered species, restricted to areas above 1300 m elevation in Kosciuszko National Park, New South Wales, Australia. This toxic, yellow and black species reaches a length of only 25–30 mm (Fig. 1). Because of its small size and cryptic nature, direct observations of feeding behavior in the wild are limited. However, studies based on gut contents show that the closely related Northern Corroboree Frog (*P. pengilleyi*) feed predominantly on ants and occasionally other small invertebrates in the wild (Pengilley 1971).

The frogs in this study were housed at Taronga Zoo, Sydney, as a captive component of a collaborative conservation program. All frogs were housed in clear plastic containers (33 cm long x 19 cm wide x 21 cm high) on a substrate of sphagnum moss above a layer of aquarium gravel (Fig. 2). Frogs were fed twice per week, and the substrate was sprayed with water the day after each feeding to help break down and wash away waste.

Observations were made on 88 three-year-old frogs, housed in containers of 2–4 individuals. On 23 September 2008, prior to feeding, all frogs were sighted and no toe-twitching behavior was observed. This is consistent with our observations that toe-twitching has never been observed prior to feeding. At 0800 h, frogs were given 15–20 live hatchling crickets per individual via a central opening in the top of each container. Observations on toe-twitching began five minutes after the addition of crickets and

COLOR REPRODUCTION SUPPORTED BY THE THOMAS BEAUVAIS FUND

FIG. 1. Captive example of an adult *Pseudophryne corroboree* at the Taronga Zoo.

continued for almost ten minutes. Each container was observed for 20–30 seconds unless each frog in the container had demonstrated the behavior earlier.

Pedal movements were observed in 84% of frogs (74 of the 88 individuals). The movements could be described as rapid twitches of the outer digit on both rear feet simultaneously. In all cases, the behavior only occurred after the presence of prey was detected by sight. The frogs faced directly toward the moving prey, remaining motionless, with the exception of the twitching digits. Frogs captured crickets with a rapid protrusion of the tongue, and toe-twitching continued immediately after the cricket was eaten, though it was not recorded when the toe-twitching ceased.

Eight frogs were observed continuously for a period of two minutes each within twenty-five minutes of feeding while live crickets were still present. The number of twitches within this time was counted through visual observation with the use of a tally counter and an average was calculated per minute. The outer digit twitched at an average rate of 108 twitches per minute

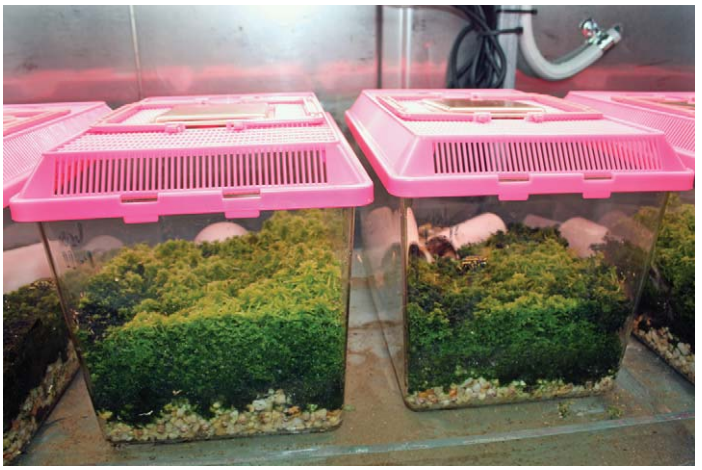

FIG. 2. Housing containing captive *Pseudophryne corroboree* at Taronga Zoo.

(maximum 128, minimum 74). The observations reported here were based on three-year old frogs, but toe-twitching in captive *P. corroboree* has been observed in all ages from metamorphs to adults, beginning as early as six days after the completion of metamorphosis (McFadden, pers. obs.).

Interestingly, for the vast majority of individuals, the twitching digit was raised off the substrate. This would minimize the potential impact of its use as a vibrational stimulus as proposed for a number of anuran species predating on smaller invertebrates (Sloggett and Zeilstra 2008). Rather, the rapid movement of a raised digit would suggest that toe-twitching in this genus might primarily be a visual stimulus, either to attract or displace prey (Radcliffe et al. 1986). Alternately, it is possible that the twitching could be simply an excited response to the presence of prey. In this study, there is no indication that the crickets responded to the twitching digit. However, it is possible that a response could be elicited from their natural prey of ants, though this was not tested in this study.

The genus *Pseudophryne* consists of about 13 endemic Australian species, all of which are small, cryptic ground-dwelling species similar to *P. corroboree*. Toe-twitching has been observed in at least one other species (*P. bibroni*; P. Byrne, pers. comm.) and might prove to be widespread within the genus. The purpose of feeding-induced pedal movements in *P. corroboree* is unknown, but this predominantly ant-feeding genus may use toe-twitching behavior to attract prey or simply to inducing prey movement, which in turn may enhance detection of prey by frogs.

Fowler's Toad (*Bufo fowleri*) and the Eastern Spadefoot (*Scaphiopus h. holbrookii*) are two ecologically similar, sympatric anuran species that inhabit early successional habitats at Cape Cod National Seashore (CACO), USA. Densities of these two species at CACO rival those from any other known locality in the northeastern U.S., likely in large part due to the abundance of optimal upland and wetland habitats present in combination with limited human development at CACO. Though locally abundant at CACO, these two species are regionally rare (*S. h. holbrookii*; Klemens 1993) and/or are in decline in areas of the northeastern U.S. (*B. fowleri* and *S. h. holbrookii*; Klemens 1993), largely as a result of habitat loss and development occurring in the region. As such, an improved knowledge of specific life-history traits (e.g., dietary composition, upland habitat preferences, movement patterns) of these two species will prove valuable to their long-term conservation in the northeastern U.S.

While several previous studies have reported on the stomach contents of *B. fowleri* (Barbour 1953; Brown 1974; Bush 1959; Bush and Menhinick 1962; Clarke 1974; Klimstra and Myers 1965) and *S. h. holbrookii* (Pearson 1955; Punzo 1992), with the exception of one study reporting stomach contents of *B. fowleri* in Connecticut (Clarke 1974), none of these studies were conducted in the northeastern U.S. Furthermore, none of these studies for either species reported results for subadult age class individuals. Thus the ability to extrapolate results from these studies to subadult *B. fowleri* and *S. h. holbrookii* in the northeastern U.S. is limited.

We report on the stomach contents of subadult *B. fowleri* and *S. h. holbrookii* captured in pitfall traps during terrestrial arthropod sampling in a coastal dune ecosystem (i.e., the "Province Lands") at CACO from early June through late September 2007. We report results only for the subadult age class (~1–2 year-old individuals, determination based on measured snout–vent lengths [SVL] as that was the only age class captured in pitfall traps. To characterize the diet of each anuran species, we calculated the *proportional occurrence* of each invertebrate taxon in the stomach contents (calculated as the proportion of stomachs containing at least one individual of that taxon) and the *proportional abundance* of each invertebrate taxon in the stomach contents (calculated as the proportion, by count, of total stomach contents comprised of each taxon).

To compare dietary overlap of the two anuran species, we calculated Schoener's diet similarity index (*Cxy*; Schoener 1968):

$$Cxy = 1 - 0.5 \Sigma \left| P_{ix} - P_{iy} \right|$$

TABLE 1. Cumulative stomach contents of captured subadult *Bufo fowleri* and *Scaphiopus h. holbrookii*.

Invertebrate Taxon	*B. fowleri*	*S. h. holbrookii*
Araneae	67	16

Lepidoptera	13	0
Lepidoptera larvae	14	0
Diptera	107	5
Formicidae	2710	60
Hymenoptera (excluding Formicidae)	4	0
Total	3008	128

where P_{ix} and P_{iy} are the proportion of species' *x* and *y* diet comprised of the i^{th} prey taxon. *Cxy* ranges from 0–1 with values approaching 1 indicating greater dietary overlap between species.

To examine dietary niche breadth of the two anuran species, we calculated Hurlbert's niche breadth (*B'*; Hurlbert 1978):

$$B' = 1/\sum (p_j^2/a_j)$$

where, for each species, p_j is the proportion of individuals containing the j^{th} prey taxon in their stomach, and a_j is the proportion of total stomach contents over all individuals comprised of the j^{th} prey taxon. For purposes of comparison we used Hurlbert's standardized niche breadth (B'_A; Hurlbert 1978):

$$B'_A = (B' - a_{min})/(1 - a_{min})$$

where a_{min} is the smallest observed proportion of all the prey taxa for a given species. B'_A ranges from 0-1 and represents the ratio of observed niche breadth to the maximum possible niche breadth.

A total of 76 subadult *B. fowleri* (SVL mean: 36.1mm, range: 25–45 mm) and 18 subadult *S. h. holbrookii* (SVL mean: 36.6 mm, range: 26–45 mm) were captured and had their stomach contents analyzed. Of the total individuals captured, ~6% (5/76) of *B. fowleri* and ~11% (2/18) of *S. h. holbrookii* had empty stomachs. Excluding individuals with empty stomachs, the number of prey items per stomach was greater for *B. fowleri* (mean = 42.37, range = 1–141; total = 3008) than for *S. h. holbrookii* (mean = 8.00, range = 1–25, total = 128).

Fourteen different invertebrate prey taxa and life stages were identified in the anuran stomachs; 13 of these were present at least once in *B. fowleri* stomachs and nine were present at least once in *S. h. holbrookii* stomachs (Table 1). Formicidae was the dominant prey taxon in the stomachs of both anurans, comprising 88% and 90% of the *B. fowleri* diet and 56% and 47% of the *S. h. holbrookii* diet based on proportional occurrence and abundance, respectively (Table 2). The Schoener diet similarity index was 0.556, indicating modest dietary overlap between the two study species. Lastly, the standardized Hurlbert's niche breadth was greater for the stomach contents of *S. h. holbrookii* (B'_A = 0.152) compared to *B. fowleri* (B'_A = 0.028).

Both species contained a diversity of invertebrate taxa in their stomachs, and although the total number of taxa consumed by *B. fowleri* (13) was greater than by *S. h. holbrookii* (9), the proportion of the diet represented by the various taxa was more highly skewed in *B. fowleri* than in *S. h. holbrookii*, which accounted for the smaller dietary niche breadth of *B. fowleri*. *Bufo fowleri* appeared to be an ant (Formicidae) specialist; ants accounted for 88–90% of the diet (by proportional abundance). *Scaphiopus h. holbrookii* appeared to be more of a dietary generalist; five invertebrate taxa were required to account for >90% of the diet (by proportional abundance). The larger dietary niche breadth of *S. h. holbrookii* compared to *B. fowleri* suggests that the former species may be more of a dietary generalist than the latter. This is generally consistent with results obtained from other studies in other geographic locations comparing individual species of these two families (Anderson et al. 1999; Smith et al. 2004), although one previous study found a similar niche breadth for one *Bufo* and one *Scaphiopus* species (Punzo 1992). The broader dietary niche breadth of *S. h. holbrookii* may be an evolutionary adaptation that enables this species to coexist with ecologically similar, dietary specialists such as *B. fowleri* and/or cope with the highly dynamic conditions of the coastal dune ecosystem in this study area (Anderson et al. 1999).

The importance of ants in the diet of subadult *B. fowleri* and *S. h. holbrookii* in our study is consistent with results reported in several previous studies of *B. fowleri* (Brown 1974; Bush and Menhinick 1962; Clarke 1974; Klimstra and Myers 1965) and *S. h. holbrookii* (Pearson 1955; Punzo 1992). In fact, the percentage of *B. fowleri* diet comprised of ants that we observed (88-90%) is the largest reported value that we are aware of for any *Bufo* species

"—" indicates that there were no individuals of that invertebrate taxon present

worldwide. The ability to eat ants and other noxious and armored invertebrates (e.g., beetles; Coleoptera) may be an adaptation that insures an adequate food supply for these anuran species, as there is little competition for these invertebrate groups from other predators (Clarke 1974). Moreover, consuming large numbers of ants to meet the species' dietary needs may be highly adaptive for these anurans because the ant populations may be capable of sustaining very high predation rates since most of the ants eaten by anurans are workers and not reproductive units. As stated by Toft (1980), "ant specialists are more like grazers or browsers that eat the leaves of a tree rather than like predators that take whole individuals". Consequently, anuran predation may have relatively limited impact on the availability of ants. Additionally, the toxic skin secretions of some anurans (including members of Bufonidae and Pelobatidae) are at least partially sequestered from dietary sources (primarily ants and beetles; Isacch and Barg 2002; Saporito et al. 2004). Therefore, a diet comprised of a relatively large number of ants and/or beetles (as is the case for *B. fowleri* and *S. h. holbrookii* in this study) may be necessary to produce the toxic secretions used as a chemical defense against potential predators. The use of toxic skin secretions as a defense against potential predators is well documented in Bufonidae and Pelobatidae (Duellman and Trueb 1986). In fact, toxic skin secretions of *S. h. holbrookii* can cause symptoms similar to an allergic reaction in humans, including watery irritated eyes, runny nose, sneezing, and strong burning sensation in the nose and eyes during and subsequent to handling of individuals (B.C. Timm, pers. obs.).

Differences we observed between species in the proportion of the diet comprised of ants (*B. fowleri*, 88–90%; *S. h. holbrookii*, 47-56%) may be an indication of differing feeding strategies. Specifically, other investigators have noted that anuran species with a higher proportion of ants (and/or termites) in their diet are more active foragers than those with a comparatively lower proportion of ants (and/or termites) in their diet (Gerritsen and Strickler 1977; Krebs 1978; Toft 1980). These authors suggest that prey species that are patchily distributed in space and time (such as ants and termites) are more likely to be discovered and eaten by actively foraging predators than by sit-and-wait predators. Thus, *B. fowleri* may be more of an active forager while *S. h. holbrookii* may be more of a sit-and-wait predator. While we are not aware of any published studies on the foraging strategy of subadults of either species, our preliminary results from nocturnal radio-telemetry work on adult *S. h. holbrookii* suggest that they are in fact best characterized as sit-and-wait predators (B. C. Timm, unpubl. data).

Results from this study provide the first published account of the diets of subadult *B. fowleri* and *S. h. holbrookii*. In addition to a general understanding of dietary composition, these results also provide insight into potential feeding strategies exhibited by these species as well as potential interspecific competition between these species via dietary overlap. Though we only captured subadult individuals of the two study species, we suggest that future studies examining diets of individual and sympatric amphibian species include an assessment of these attributes for different age classes (e.g., newly metamorphosed juveniles, subadults, and adults) of the focal species of interest. Results from such studies will provide much needed information regarding ontogenetic dietary consistency/shifts, an aspect of amphibian ecology for which there is currently a dearth of scientific information.

Acknowledgments.—We thank C. Raimond, I. Anderson, N. Freidenfelds, and S. Buchanan for help with data collection, P. Paton and T. Tupper for reviews of previous drafts of this manuscript, and B. Cook and C. Phillips at Cape Cod National Seashore for logistical support throughout the course of this research. This study was partially funded by a PMIS grant and a CESU extension from the U.S. National Park Service and a Robert & Patricia Switzer Environmental Fellowship to B. Timm. Handling of animals was conducted under a University of Massachusetts Amherst Institutional Animal Care and Use Protocol and collection permits granted by the Massachusetts Division of Fisheries and Wildlife. This material is based upon work supported by the Cooperative State Research Extension, Education Service, US Department of Agriculture, the Massachusetts Agricultural Experiment Station, and the Department of Natural Resources Conservation, under project number 3456.

Scott and McDiarmid (1984:2) stated that "Most early attempts to clarify the relationships of *Trimorphodon* have been misled by an inadequate description of the hemipenis…" Recently, the *Trimorphodon biscutatus* complex has received some significant attention both in molecular and morphological analyses (Devitt 2006; Devitt et al. 2008) and much of its evolutionary history is becoming better understood. However, these recent studies have not included hemipenial morphology and earlier papers appear to provide inaccurate descriptions (e.g., Klauber 1940; Scott and McDiarmid 1984; Smith 1941). Cope (1895, 1900) dissected the tails of male *Trimorphodon* and noted that their hemipenes possessed calyces. This was later rejected by Scott and McDiarmid (1984) and although Savage (2002) stated that *Trimorphodon* possess calyces, he did not provide a reference or evidence for his statement. In this study we dissect, illustrate, and describe the hemipenis of one of the species in the *Trimorphodon biscutatus* complex, *T. quadruplex*.

Methods

A partially everted left hemipenis from a large adult-male specimen (SVL 1075 mm; tail length 226 mm; 89 divided subcaudals) of *Trimorphodon quadruplex* (UTA R-44978) was measured and then removed at the base. We followed the hemipenial preparation procedures of Myers and Cadle (2003) and Zaher and Prudente (2003) with the addition of blue petroleum jelly, inserted into the base of the hemipenis and resulting in full eversion of the hemipenis. The latter method is further described and illustrated by Smith and Ferrari-Castro (2008). Finally, we examined the retracted left hemipenis of USNM 32274—*in situ*, as originally studied and illustrated by E. D. Cope in 1895 and 1900. The description follows the terminology of Dowling and Savage (1960), Myers and Campbell (1981), and Zaher (1999), as adopted by Savage (2002).

Hemipenis Description

Trimorphodon quadruplex (UTA R-44978); Figs. 1, 2

The specimen comes from the town of Santa Cruz, Guanacaste, Costa Rica, and was collected by M. Sasa in 1997. The everted left hemipenis extends approximately 55 mm in length and is 12.5 mm at its maximum width. The pedicel of the hemipenis is long and narrow, extending approximately 20 mm, and its distal half is covered in minute spines. The spinous truncus occupies approximately 10 mm of the hemipenis. This region possesses about 87 hooks (noticeably large spines), ranging from about 1.0 to 1.6 mm in length. When fully everted the spines start at the beginning of the 8th subcaudal and end at the 13th subcaudal. The calyculate apical region extends to the 21st subcaudal. The single semicentripetal *sulcus spermaticus* extends to the tip of the organ. Following the spines is the spinous and papillate calyx region, extending for about 25 mm and includes 20 rows of calyces on the sulcate side. The calyces bear on their edges minute papilla, distally, or spines, proximally. A unique feature of the hemipenis is the enlargement of the two most proximal calyces on the asulcate side, over part of the truncus and resembling naked or striated pockets. The first and largest calyx extends about 4 mm. At the apex of the hemipenis the final 2–3 rows of ornamentation consist of numerous, small papillae.

Trimorphodon quadruplex (USNM 32274); Fig. 1

The specimen comes from San Juán, Nicaragua, and was collected by M. Oviedo. The SVL could not be taken of this specimen but the tail has a length of 173 mm and has 91 subcaudals, excluding the tip. The left hemipenis was examined uneverted, as illustrated by Cope (1895 and 1900). This hemipenis extends in length to the 25th subcaudal, the first minute spines appear at the level of subcaudal 8, and the first hooks at the level of subcaudal 14.

Discussion

The only illustration of *Trimorphodon* hemipenes we are aware of was presented twice by Cope (1895: plate 30, figure 7; 1900: plate 28, figure 7). Cope (1900, p. 1101) mentioned examining only four specimens of *T. biscutatus* (then including *T. quadruplex*), so his illustration was thought to come from one of them. Cope (1861) mentioned a specimen of *T. biscutatus* (= *T. quadruplex*) from Realejo Nicaragua (USNM 5569) and in 1870 (1869) de-

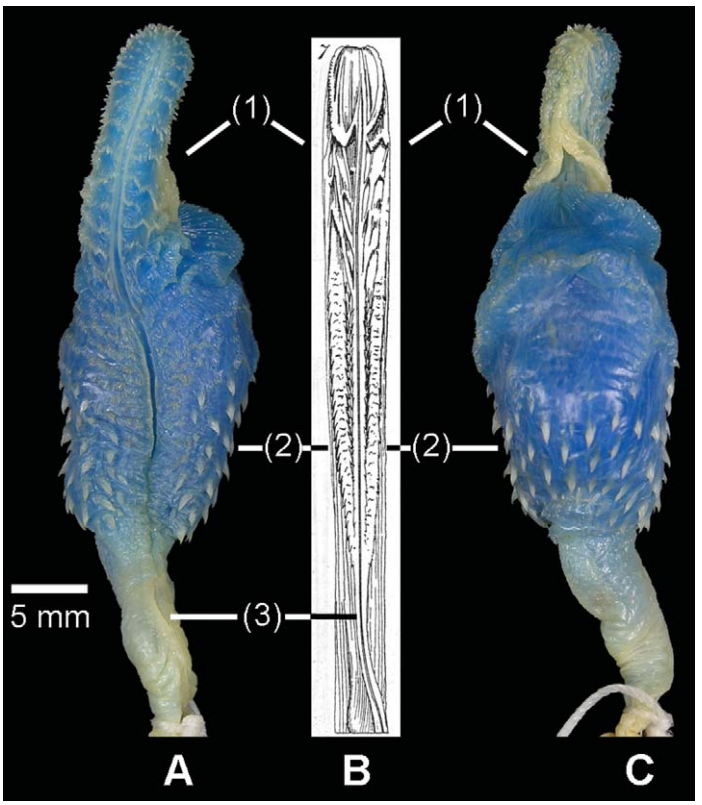

Fig. 1. Hemipenis of *Trimorphodon quadruplex*. Sulcate (A) and asulcate (C) view of the left hemipenis of UTA R-44978, compared to Cope's (1900: plate 28, image 7) *in situ* illustration of the left organ of USNM 32274 (B), showing calyces (1), spines (2), and sulcus spermaticus (3).

FIG. 2. Side view of the hemipenis of *Trimorphodon quadruplex* (UTA R-44978), showing the protruding lower calyces and curvature of the hemipenis.

scribed *T. major* (shortly synonymized by him as *T. biscutatus*, Cope 1876 [1875], p. 131) from Tehuantepec, Oaxaca, based on three specimens (two specimens mentioned by him but three cotypes, USNM 30427–9, are listed by Cochran 1961). However, our examination determined that the hemipenes of none of these specimens were examined by Cope. The illustrated hemipenis belongs to the left hemipenis of a *T. quadruplex* (as currently recognized by Devitt et al. 2008), USNM 32274, a paratype from San Juan, Nicaragua (Smith 1941), which was returned by Cope's estate after his death. Our figure 1 includes an image of Cope's illustration for direct comparison of the retracted and the everted hemipenes. The existence of calyces is quite obvious on the fully everted hempenis (Figs. 1, 2), and as mentioned by Cope (1900), these structures are very unusual.

Although beyond the scope of this study, we examined specimens of *T. biscutatus* (UTA R-51832, from Carretera El Camaron-Mitla Km 106 on Mex 190, Oaxaca) and *T. paucimaculatus* (UTA R-52654, from Arroyo Colorado, Municipio La Huerta, Jalisco) and found these same features (e.g., unusual and extended proximal calyces) on their everted hemipenes. A thorough analysis of the hemipenis of the other species of *Trimorphodon* (*biscutatus*, *lambda*, *lyrophanes*, *paucimaculatus*, *tau*, *vilkinsonii*) is needed to add morphological support to the currently recognized species. King et al. (2009) found that reproductive behavior may correlate with hemipenis morphology. An investigation of the reproductive behavior causing this odd morphological evolution would be interesting.

Acknowledgments.—We thank T. Hartsell, K. Tighe, R. Wilson, A. Wynn, and R. McDiarmid (USNM), and C. J. Franklin and J. A. Campbell (UTA) for providing space at their institution and allowing us to examine and dissect hemipenes from *Trimorphodon* specimens under their care. This paper is based in part upon work supported by the National Science Foundation under grant no. DEB-0613802 to Jonathan A. Campbell and DEB-0416160 to ENS; and a grant from the Instituto Bioclon, Mexico, to ENS. Necessary permits for Mexican specimens were issued by SEDUE (now SEMARNAT).

Green Salamanders, *Aneides aeneus*, occur as two distinct populations in the eastern United States. The more extensive population is located throughout the Cumberland and Allegheny Mountain regions from Pennsylvania to Alabama and northeastern Mississippi. The smaller disjunct population is located in the Blue Ridge Mountains of Georgia, South Carolina, and North Carolina (Petranka 1998). A study conducted in the Blue Ridge Escarpment of western North Carolina, northwestern South Carolina, and northeastern Georgia documented a 98% decline in some populations of Green Salamanders since 1970 (Corser 2001). The U.S. Fish and Wildlife Service currently recognizes *A. aeneus* as a species of concern. The Blue Ridge Escarpment population is listed as rare in Georgia, endangered in North Carolina, and a species of special concern in South Carolina. Corser (2001) attributed declines to climate change, loss and alteration of habitat, a chytrid fungal pathogen, and exploitation through collection by researchers. The issue of forest ecosystem alteration and its importance in understanding Green Salamander arboreality and species declines have recently garnered attention (Pauley and Watson 2005; Waldron and Humphries 2005).

Green Salamanders are generally considered crevice-dwelling species associated with rock outcrops, and only "weakly" arboreal (Pauley and Watson 2005). Green Salamander morphology is consistent with rock-crevice habits, particularly their dorso-ventrally compressed bodies with elongate limbs and toes with expanded square toe tips (Petranka 1998). Most associations with Green Salamanders and non-rock outcrop habitats were reports of large numbers of individuals under the bark of dead and fallen trees, particularly large American Chestnut (Barbour 1949). Contradicting the perception of Green Salamanders as weakly arboreal, Waldron and Humphries (2005) recently documented large numbers of Green Salamanders using arboreal habitats in some Blue Ridge Escarpment populations. Using day and night searches with flashlights, they recorded 345 Green Salamander observations between April and October, of which 43% occurred in trees, 41% in rock outcrops, and only 15% on or in logs. They also reported arboreal nesting. Additionally, Wilson (2003) documented Green Salamanders in woody and arboreal habitats at sites throughout the Blue Ridge Mountains. These studies raise questions about the importance of arboreal habits to Green Salamander populations and highlight the potential need to include methods for searching arboreal habitats as part of Green Salamander monitoring.

Although the technique used by Waldron and Humphries (2005) was successful at discovering many salamanders using arboreal habitats, it was very time consuming (more than 210 h over a 3.5 yr period) and difficult to standardize. Survey success varied widely based on weather conditions and other variables. Further, the effectiveness of the technique is likely to vary greatly among observers who differ in ability to spot salamanders high in trees. A standardized and less labor-intensive technique for studying arboreal habits of Green Salamanders would be useful.

Artificial cover is widely utilized as a technique for standardized monitoring of terrestrial salamanders (Houze and Chandler 2002; Monti et al. 2000). Artificial cover can provide the necessary microclimates to attract salamanders during diurnal retreat, making detection of species less dependent upon the immediate climate. Artificial cover generally involves the application of boards or other materials to the forest floor, or litter bags or baskets along stream banks (Monti et al. 2000). We are not aware of any standardized artificial cover technique for capturing salamanders in arboreal habitats. However, burlap fabric attached to trees (known as burlap bands) has been used to sample arboreal invertebrates and reptiles (Campbell and Sloan 1977; Duguay et al. 2000; Horn and Hanula 2006; Reardon 1976). In addition to attracting invertebrates, these artificial shelters are sometimes occupied by salamanders, including Red-backed Salamanders (*Plethodon cinereus*) and Northern Two-lined Salamanders (*Eurycea bislineata*) (J. Waldron, pers. comm.). Attaching artificial cover to trees at distance and heights determined within the predicted range of Green Salamanders may provide a reliable technique for capturing Green Salamanders occupying arboreal habitats. In 2005, we deployed burlap bands on trees at four study sites in Georgia and North Carolina in order to determine whether Green Salamanders will occupy burlap bands as an artificial cover type.

Methods.—The populations of Green Salamanders surveyed were located in the Nantahala National Forest in Jackson County, North Carolina, and Chattahoochee National Forest in Rabun

County, Georgia. Both populations are located in the Blue Ridge physiographic province. We identified three study sites in the Chattahoochee National Forest and one site in the Nantahala National Forest where Green Salamanders were known to occur (M. Elliott, Georgia Natural Heritage Program, pers. comm.). The vegetation at all sites consists of mixed, uneven-aged conifer/hardwood forest with dense Rhododendron (*Rhododendron maximum*) midstory. The dominant tree species at the sites are Eastern Hemlock (*Tsuga canadensis*), Red Maple (*Acer rubrum*), Tulip Poplar (*Liriodendron tulipifera*), Frasier Magnolia (*Magnolia fraseri*), White Oak (*Quercus alba*), Eastern White Pine (*Pinus strobus*), Pignut Hickory (*Carya glabra*), Northern Red Oak (*Quercus rubra*), Chestnut Oak (*Quercus montana*), and Witchhazel (*Hamamelis virginiana*) (Gordon 1952). Annual precipitation in the area ranges from 215–254 cm (Bruce 1968). The rock outcrops at sites known to be occupied by Green Salamanders are composed of granite. The deep, narrow crevices and asymmetrical walls provided by the granite outcrops offer individuals protection from sunlight (Bruce 1968) and predators. Green Salamanders overwinter, mate, and lay eggs within the outcrops (Pauley and Watson 2005; Petranka 1998). The site in the Nantahala National Forest is located at 950 m elevation (Gordon and Smith 1949) with 15% slope and 75% canopy cover. The three sites in the Chattahoochee National Forest range in elevation from 600–750 m with 10–55% slope and 25–65% canopy cover. Herbaceous understory is dominated by Galax (*Galax aphylla*), Hayscented Fern (*Dennstaedtia punctilobula*), Pansy (*Viola* sp.), Striped Wintergreen (*Chimaphila maculata*), Speckled Wood Lily (*Clintonia umbellata*), and Mountain Laurel (*Kalmia latifolia*) (Gordon 1952).

Burlap fabric was washed with a concentrated liquid detergent formulated for use in laboratories to remove chemicals that aid water resistance and may potentially harm salamanders (Liqui-Nox®). Prior to use, the burlap fabric was tested for anions at U.S. Forest Service, Coweeta Hydrologic Laboratory and results show the fabric contained less than 0.5 ppm of chloride, sulfate, nitrate, phosphate, and bromide. At each site, burlap strips measuring 76.2 cm by 45.7 cm were attached to hardwood trees with hemp rope two meters from the ground on 15 trees with a diameter at breast height (DBH) ≥ 20.3 cm (Fig. 1). Trees ranged from 1-50 m from the rock outcrops. Large hardwood trees were selected because previous research suggested that Green Salamanders are observed on large hardwoods compared to conifers (Waldron and Humphries 2005).

We visited each site three times per month (~1-2 weeks between visits) from June–December 2005. During each visit, we lifted the fabric and searched the entire area under the burlap with a flashlight. For comparative purposes, we also searched crevices for salamanders on each occupied rock outcrop during each visit. We recorded the number and species of salamanders observed, measured individuals (we did not capture and measure salamanders observed in rock crevices), and recorded distance from the nearest occupied rock outcrop. Green Salamanders under burlap were classified as adults (> 44.5 mm total length, TL), sub-adults (29.5–44.4 mm TL), or juveniles (< 29.5 mm TL) (Waldron and Humphries 2005). Salamanders were released at their capture location. Sites were surveyed during the day, at dusk, and after dark.

Results.—Over 16 sample days, we observed 31 salamanders under burlap, only 11 of which were Green Salamanders (Table 1). We also observed Southern Appalachian Slimy Salamanders (*Plethodon chattahoochee*), Southern Gray-cheeked Salamanders (*Plethodon metcalfi*), and a single Ocoee Salamander (*Desmognathus ocoee*). We observed a greater number (16) of juvenile Southern Appalachian Slimy Salamanders under burlap than Green Salamanders. By comparison, we observed 80 salamanders in rock outcrops including 57 Green Salamanders during the same sample period (Fig. 2). Though we did not systematically search for salamanders on non-burlap trees, we did not observe any salamanders on trees outside of burlap covers. Further, while we observed few Southern Gray-cheeked Salamanders under burlap, we did observe them routinely off the forest floor on Rhododendron during wet nights. All Green Salamanders and Southern Appalachian Slimy Salamanders found under the burlap were sub-adults, while the Ocoee Salamander and the Southern Gray-cheeked Salamanders were adults. We determined Ocoee Salamander and Southern Gray-cheeked Salamander adult and juvenile size classes by comparing measurements of each individual to published size classes for the two species (Petranka 1998). Southern Gray-cheeked Salamanders were observed singly, while up to five Southern Appalachian Slimy Salamanders were observed under one piece of burlap at the same time. One Green Salamander was observed under a piece of burlap with three Southern Appalachian Slimy Salamanders. All individu-

FIG. 1. Burlap bands were attached to hardwood trees with hemp rope two meters from the ground on trees with a diameter at breast height (DBH) ≥ 20.3 cm to assess arboreality of Green Salamanders in the Nantahala National Forest, North Carolina and Chattahoochee National Forest, Georgia, 2005.

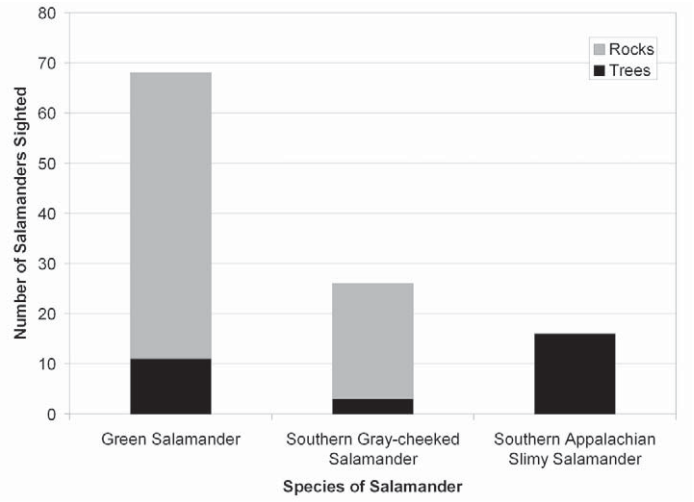

FIG. 2. Number of Green Salamanders, Southern Gray-cheeked Salamanders, and Southern Appalachian Slimy Salamanders in and on rocks versus the number observed under the burlap cover on trees in Chattahoochee National Forest, Georgia, and Nantahala National Forest, North Carolina, 2005.

als were observed between the burlap and tree bark, not between the two layers of the burlap at the top of the band where the burlap was attached to the tree with hemp rope (Fig. 1).

Salamanders were only observed beneath burlap from August–November. However, Green Salamanders and Southern Gray-cheeked Salamanders were observed in the rock outcrops as early as May, when we began establishing transects, until late November. Green Salamanders were found a maximum distance of 10 m from rock outcrops. Southern Gray-cheeked Salamanders were found up to 7 m from rock outcrops. Southern Appalachian Slimy Salamanders were never observed on the rock outcrop; they were only observed under burlap on trees located within 1 m of the rock outcrop.

No salamanders were observed under burlap in surveys conducted before 1600 h and individuals were most abundant under burlap in months with high precipitation (correlation between cumulative monthly rainfall and number of salamanders observed under burlap: $R^2 = 0.87$, $p = 0.067$). Southern Appalachian Slimy and Gray-cheeked Salamanders were common on the forest floor. However, we never observed Green Salamanders on the forest floor, similar to Waldron and Humphries (2005). More Green Salamanders and Southern Gray-cheeked Salamanders were observed in rock crevices than on trees during our surveys.

Discussion.—Our results indicate that Green Salamanders and other terrestrial plethodontid salamanders will occupy burlap as artificial cover during periods of sufficient precipitation. That we did not opportunistically observe any Green or slimy salamanders on trees outside of burlap suggests that despite low captures of salamanders the burlap did improve observation of arboreal habitat use by salamanders. In contrast to the observations of Waldron and Humphries (2005), we did not observe any Green Salamanders on trees during day searches. All arboreal observations of salamanders occurred after dusk following recent rains. This is consistent with other observations of plant climbing behavior in terrestrial *Plethodon* (e.g., Jaeger 1978) and strongly suggests that all salamanders, including Green Salamanders, were moving from forest floor or rock habitats up the trunks of trees to forage on rainy nights. We did observe large numbers of invertebrates under the burlap. We did not capture any Green Salamanders on trees farther than 10 m from the associated rock outcrops, which contrasts sharply with prior observation of Green Salamanders up to 40 m from rock outcrops at one of the same study sites (Waldron and Humphries 2005). This may simply be an artifact of the greater sampling effort of Waldron and Humphries increasing the opportunity to detect Green Salamanders farther from rock outcrops.

One interpretation of our results is they are more consistent with the characterization of Green Salamanders as "weakly arboreal," and their use of trees may be comparable to that of other forest plethodontids. Alternatively, the difference between our results and those of Waldron and Humphries (2005) may be an artifact of the suitability of burlap as refugia. The burlap did not retain much water and the surface under the burlap usually dried within days of a rain. Dry conditions are unfavorable to salamanders, and may explain why we did not observe any individuals under the burlap during the day. Waldron and Humphries (2005) report Green Salamanders in trees, often tucked beneath small flaps of bark, even during dry periods. Burlap apparently did not adequately simulate loose bark that could be used by Green Salamanders; therefore, burlap may be suitable for use if surveying arboreal foraging habits of plethodontids, but unsuitable for measuring other arboreal habits. The effectiveness of burlap might be improved if a strip of foam is attached at the top of the burlap flap to absorb and retain water. Alternately, another substrate such as slabs of real or artificial bark could be attached to trees to provide better microclimates for salamanders.

Further, Waldron and Humphries (2005) found that Green Salamanders prefer American Beech trees and hardwood trees over other tree species. Therefore, conducting a study to determine

TABLE 1. Number of individuals of each species of salamander observed at sites surveyed using burlap bands attached to trees in Chattahoochee National Forest, Georgia, and Nantahala National Forest, North Carolina, 2005. T = Trees, RO = Rock Outcrops.

Salamander Species	Chattahoochee I		Chattahoochee II		Chattahoochee III		Nantahala	
	T	RO	T	RO	T	RO	T	RO
Aneides aeneus	0	2	5	3	4	23	2	31
Plethodon metcalfi	0	0	0	5	0	8	3	9
Plethodon chattahoochee	0	0	16	0	0	0	0	0
Desmognathus ocoee	0	0	1	0	0	0	0	0
Total	0	2	22	8	4	31	5	40

Green Salamander tree species preference is important in assessing arboreality of the species. Trees in this study were chosen because of their size since American Beech trees were scarce at our sites or did not meet size requirements. Tree preference may be because of species of invertebrates found on different species of trees. Future studies include determining if a correlation exists between number of arthropods on trees and number of salamanders present.

Number of salamanders observed under burlap on trees and in the rock outcrops in November 2005 supports earlier findings (Waldron and Humphries 2005) that Green Salamanders as well as Southern Gray-cheeked Salamanders and Southern Appalachian Slimy Salamanders (Petranka 1998) show strong seasonal use of the forest floor and trees. We did not observe any species of salamanders under burlap in trees after November. Most likely Green Salamanders move to rock outcrops where they overwinter, then emerge and disperse in late-March or early-April (Waldron and Humphries 2005). Southern Appalachian Slimy Salamanders are suggested to overwinter in caves in Georgia. Southern Gray-cheeked Salamanders are suggested to overwinter in the ground in extensive burrows. Southern Gray-cheeked Salamanders move to their overwintering habitats and emerge and disperse in the spring at approximately the same time as Green Salamanders (Petranka 1998); therefore, surveys assessing arboreal habitat use should be conducted from August–November or late March–May.

The issue of arboreal habitat use by Green Salamanders and its importance to their population ecology remains unclear. While our results do not disagree with the characterization of Green Salamanders as "weakly arboreal", the results of Waldron and Humphries (2005) suggest that studies of Green Salamander arboreal habits needs greater attention. A 100-m buffer zone around each outcrop containing Green Salamanders has been suggested (Petranka 1998) to maintain cool microclimates on rock outcrops. If arboreal habitats are as important as Waldron and Humphries (2005) observations suggest, then the importance of forest buffers goes beyond maintenance of mild climates on rock outcrops. Though we did not capture large numbers of Green Salamanders under burlap, numerous individuals of other Southern Appalachian Salamanders were found. It should be noted that our study was only conducted during a few months during one season. Just as coverboards used in other reptile and amphibian studies oftentimes need time to "age" before they are successful, burlap or other artificial cover objects may increase in efficiency as they remain in the forest. We suggest the use of numerous sampling techniques for Green Salamanders and other salamander species in the Appalachians, as all methods have their benefits and biases.

Acknowledgments.—Thanks to M. Elliott for logistical help and J. W. Gibbons for contributing throughout this project. We thank J. Jensen and D. van Dijk for reviewing our manuscript and J. Deal, C. Brown, and J. Knoepp at U.S. Forest Service, Coweeta Hydrologic Laboratory for volunteering their services and information. We are indebted to L. Williams and the North Carolina Wildlife Resources Committee as well as C. Wentworth and the United States Department of Agriculture Forest Service for their help obtaining permits to conduct our research. Green salamanders were captured in North Carolina under Endangered Species Permit NC-2005 ES150 from the North Carolina Wildlife Resources Commission. Green salamanders were captured in the Chattahoochee and Nantahala National Forests under permit FS-2400-8 from the United States Department of Agriculture-Forest Service.

Stream salamanders are often the most abundant vertebrates in headwater streams (Peterman et al. 2008) and they play an integral role as both predators and prey in these ecosystems (Greene et al. 2008; Resetarits 1997). Because stream salamanders often use both terrestrial and aquatic habitat, they may be vulnerable to the degradation or contamination of either environment (Semlitsch 2000). As a consequence, stream salamanders have proven to be susceptible to terrestrial disturbances such as deforestation (Crawford and Semlitsch 2008; Johnston and Frid 2002) and aquatic disturbances such as siltation (Lowe et al. 2004) and stream acidification (Kucken et al. 1994). Because of this susceptibility to a range of environmental perturbations, it is widely believed that stream salamanders are useful as biological indicators of ecosystem health (Rocco and Brooks 2000; Welsh and Droege 2001). As a result, they have been increasingly incorporated into stream and watershed monitoring efforts (Jung et al. 2000).

A wide range of sampling techniques may be used to study stream salamanders, including active techniques such as dipnetting and visual encounter surveys (Grover 2006; Shaffer et al., 1994), or passive techniques such as funnel trapping or leaf litter bag sampling (Pauley 1995; Willson and Dorcas 2003). In this study, we examine the utility of two common techniques for monitoring stream salamanders: leaf litter bag sampling and nighttime visual encounter surveys (VES). The leaf litter bag refugia technique has long been used to sample aquatic invertebrates (Hilsenhoff 1969; Crossman and Cairns 1974), and has more recently been described as a method for surveying stream salamanders (Pauley 1995). Leaf litter bags may be ideal for many salamander monitoring efforts because they are cheap, non-destructive, easy to employ, and likely result in minimal observer bias (Chalmers and Droege 2002; Jung and Pauley 2003; Pauley and Little 1998; Waldron et al. 2003). Although leaf litter bags have been recommended for developing occupancy estimates for certain aquatic salamanders (Chalmers and Droege 2002; Pauley and Little 1998), this technique may be biased towards the larval and juvenile lifestages (Pauley and Little 1998). Furthermore, larval captures from litter bag sampling may be highly variable and may not demonstrate a clear relationship with actual abundances (Chalmers and Droege 2002; Waldron et al. 2003). Visual encounter surveys require relatively little equipment, are effective for a large range of species, and can be conducted across a wide range of habitats including terrestrial, riparian, and aquatic (Toft et al. 1982; Pough et al. 1987). However, visual encounter surveys may have variable results due to differences in capture rates between researchers (Crump and Scott 1994; but see Marsh 2009) and may yield results that are highly dependent on prevailing stream and weather conditions (Barr and Babbitt 2002; Crump and Scott 1994).

Another potential source of variation in stream salamander captures is the variability in stream substrate complexity that often exists at both a local and regional scale. A number of studies have demonstrated that the species richness of stream organisms is positively correlated with habitat complexity (Gorman and Karr 1978; Reice 1980; Schlosser 1982). In the southern Appalachians, larvae of many stream-dwelling salamander species frequently utilize leaf litter, rock cover, and interstitial spaces in gravel streambeds (Petranka 1998). As a result, we believe that variability in stream substrate complexity may influence both salamander abundance and species richness on a local scale, as well as the accuracy of abundance indices derived from capture data. For example, variability in leaf litter bag captures between sites may be at least partially explained by salamanders preferring litter bags no more than surrounding cover objects in areas of higher substrate complexity (Chalmers and Droege 2002).

Although there are several potential techniques for sampling stream salamanders, researchers may be limited by practical considerations such as time, resources, and the availability of surveyors. The primary objective of this study was to determine how stream substrate complexity influences both capture rates and observed species richness of stream salamanders of two common sampling techniques with the goal of developing monitoring recommendations to optimize capture rates and species detection ability. Specifically, we sought to compare 1) catch-per-unit-effort (CPUE) and observed species richness between sampling techniques and 2) CPUE and observed species richness between stream segments with low and high substrate complexity.

Methods.—We conducted this study at four first to second-order streams in the vicinity of Highlands, North Carolina, USA. The streams sampled were located within 8 km of the Highlands Biological Station (35.0323ºN, 83.1117ºW), (35.0312ºN, 83.1115ºW), (35º0317ºN, 83.1120ºW), (35.0209ºN, 83.1323ºW). At each stream, we surveyed two separate 10-m transects; one with simple substrate and one with complex substrate. Although substrate complexity would typically be considered a continuous variable, we purposefully selected transects with either an extreme abundance or a complete lack of cover objects and treated substrate complexity as a dichotomous variable. Transects with complex substrate had >85% in-stream habitat cover (boulder, cobble, leaf litter, coarse woody debris), while those with simple substrate were entirely sandy or muddy with only sparse leaf litter for cover. At all four streams, the two transects were separated by a minimum of 50 m. Stream segments were selected by systematically searching 13 streams in the area around the Highlands Biological Station. The four streams included in this study were the only streams which met the aforementioned criteria of having: 1) a potential 10-m transect containing exclusively simple substrate and 2) a potential 10-m transect, at least 50 m from the first transect, containing complex substrate.

We constructed 40 leaf litter bags (Pauley and Little 1998) from 1.9 cm^2 polypropylene mesh. To create each leaf litter bag we filled 70 x 70 cm squares of netting with dry leaf litter, twisted the

corners together, and cinched a cable tie around the joined corners. On 18 June 2008, five leaf litter bags were systematically placed throughout each 10-m transect and were covered or surrounded by rocks to keep them in place in the stream. All bags were placed in at least 4 cm of water and were submerged to no more than three fourths of the bag's height.

Leaf litter bags were checked on 2, 16, and 30 July. During sampling, leaf litter bags were removed quickly from the stream and placed in a large white dishpan. As each bag was lifted from the water, a 15 x 20 cm baitnet was swept beneath it to capture any salamanders taking refuge underneath. Bags were held above the dishpan and shaken from side to side, dipped into the stream, and then shaken from front to back for a total of approximately 15 seconds. The water, sediment, and debris collected in the trays were then poured through the baitnet. The sediment and debris from the baitnet was then manually searched for salamanders. All captured salamanders were identified to species and then released within 1 m of the point of capture. We also conducted a time-constrained search (VES) for larval and adult salamanders at each transect in order to compare count data and observed species richness to those obtained with leaf litter bag sampling. Each 10 m transect was searched by two observers for a total of 30 minutes between 2100 h EST on 4 August 2008 and 0200 h EST on 5 August 2008. Salamanders were captured and identified to species and released in the stream.

With the goal of assessing techniques in terms of their ability to optimize capture rates during sampling efforts, we used our count data to compare the catch-per-unit-effort (CPUE) for each sampling technique. This capture rate is reported as the number of salamanders caught per hour of sampling. It is difficult to estimate total sampling time using leaf litter bags because they are in the water "sampling" for days or weeks before being checked. Therefore, the time we used to determine our capture rates is the total time spent by researchers actively sampling in the field. Leaf bags took 20 person-minutes to check per transect, and 60 person-minutes per transect for three days of sampling. One night of visual encounter survey took 60 person-minutes per transect.

We analyzed total CPUE data using the ANOVA procedure of SAS (SAS® Version 9.1 for Windows, SAS Institute, Cary, North Carolina). We conducted a two-way nested ANOVA to examine the effect of substrate type (simple vs. complex) and survey technique (leaf bag vs. VES) on capture rates, while accounting for the fact that our true level of replication was at the stream level. We also conducted a repeated-measures ANOVA to examine the background variability in leaf litter bag capture rates over time. Finally, we ran an independent samples t-test to compare the mean number of species detected in simple and complex substrates.

Results.—We captured a total of 690 salamanders, with leaf litter bag sampling accounting for 54% (N = 374) of total captures and VES accounting for 46% (N = 316) of total salamander captures. Larvae made up a majority of captures from both leaf litter bag sampling (89%) and VES (92%). The two techniques together detected every stream-affiliated salamander species known to be present at our study sites. We found that catch per unit effort (CPUE) did not differ significantly between litter bag sampling and VES ($F_{1,3}$= 0.21, p=0.6769; Fig. 1). Catch per unit effort from both techniques combined did not show a significant relationship with substrate complexity ($F_{1,3}$= 1.61, p=0.2941). With leaf litter bag sampling, CPUE did not significantly differ across sampling occasions ($F_{1,8}$= 1.77, p= 0.2318).

Although CPUE was similar for both sampling techniques, leaf litter bag sampling and VES sampling differed slightly in the species they captured (Table 1). The two sampling techniques each accounted for roughly half of total salamander captures, yet litter bags captured a slight majority of *Desmognathus ocoee* individuals (61%), while nighttime VES captured a majority of *D. quadramaculatus* individuals (77%). In addition, we captured one *Pseudotriton ruber* metamorph and two *Gyrinophilus porphyriticus* larvae in leaf litter bags while neither species was detected at any site during VES. Both sampling techniques captured a large number of *Eurycea wilderae* larvae, while *D. monticola* was not commonly captured using either technique (Table 1).

Overall, we detected significantly more species in transects with complex substrate using both leaf litter bags (T_6= 2.954, p=0.025) and VES (T_6= 3.0, p=0.024). Litter bag sampling detected a mean of 3.75 ± 1.26 SD species in transects with complex substrate and a mean of 1.75 ± 0.50 SD species in simple substrate. Using nighttime VES sampling we found a mean of 3.25 ± 0.96 SD species per transect with complex substrate and a mean of 2.00 ± 0.82 SD species per transect with simple substrate. Overall, surveying in complex transects tended to yield a higher observed species richness primarily because *D. monticola* and *D. quadramaculatus* were

only frequently encountered around complex, rocky substrates (Table 1).

Discussion.—Accurate estimations of amphibian abundances across time, locations, and observers require the use of standardized sampling methods and protocols (Crump and Scott 1994). Because substrate can be highly variable both within and between streams (Inoue and Nunokawa 2002; Vannote et al. 1980), it is important to determine whether this variability influences the efficacy of sampling techniques, particularly when using artificial refugia. Also, because certain sampling techniques may be inherently biased towards particular species or life stages while failing to detect others, any effect of stream substrate complexity on capture rates or observed species richness may significantly affect the utility of many survey techniques (Strain et al. 2008). Although we found no significant difference in CPUE between substrate types and between sampling methods, sampling in areas with greater substrate complexity revealed the presence of more species. For both sampling techniques, fewer species were found in areas of simple substrate than in areas of complex substrate. Stream salamander species have been shown to exhibit different substrate preferences, with *D. quadramaculatus* and *D. monticola* demonstrating a strong preference for rocky substrates (Southerland 1986). Although we found 3 *D. quadramaculatus* larvae in transects with simple substrate, the vast majority of *D. quadramaculatus* (19 of 22) and all *D. monticola* were found in transects with complex substrate (Table 1). These results are consistent with studies of other stream organisms where species richness has been found to be positively correlated with habitat complexity (Gorman and Karr 1978; Reice 1980; Schlosser 1982). Habitat complexity has repeatedly been shown to moderate predatory and competitive interactions (Babbitt and Tanner 1998; Crowder and Cooper 1982; Heck and Crowder 1991), and it has specifically been demonstrated that lotic habitat substrate complexity can decrease the susceptibility of larval salamanders to predation (Barr and Babbitt 2002). As a result, it seems likely that substrate complexity plays a critical role in sustaining high levels of salamander diversity and species richness in these headwater ecosystems.

This study demonstrates that leaf litter bag sampling and VES both have their strengths and weaknesses. Leaf litter bags are cheap, non-destructive, easy to employ, and likely result in minimal observer bias (Chalmers and Droege 2002; Jung and Pauley 2003; Pauley and Little 1998; Waldron et al. 2003). Leaf litterbags also take less time than nighttime VES sampling during repeated surveys and can be particularly useful for large scale inventories and when time-constrained sampling of individual sites is limited (Waldron et al. 2003). Although leaf litterbag sampling was relatively ineffective at capturing large body *D. quadramaculatus*, this technique did capture more *D. ocoee* than the nighttime VES technique. Further, *Pseudotriton ruber* and *Gyrinophilus porphyriticus* were only detected using leaf litter bags, which is consistent with other studies in which leaf bags effectively captured hard to detect species (Waldron et al. 2003). Visual encounter surveys are simple and require relatively little equipment. They are not as biased towards any particular life stage, and they can be implemented over a wide range of habitats. Because different sampling techniques appear to target different ranges of species, we believe the use of more than one sampling technique may allow more accurate estimation of stream salamander abundances and species richness. Following this recommendation, while considering the effects of stream substrate complexity on salamander diversity, can result in more effective stream salamander monitoring.

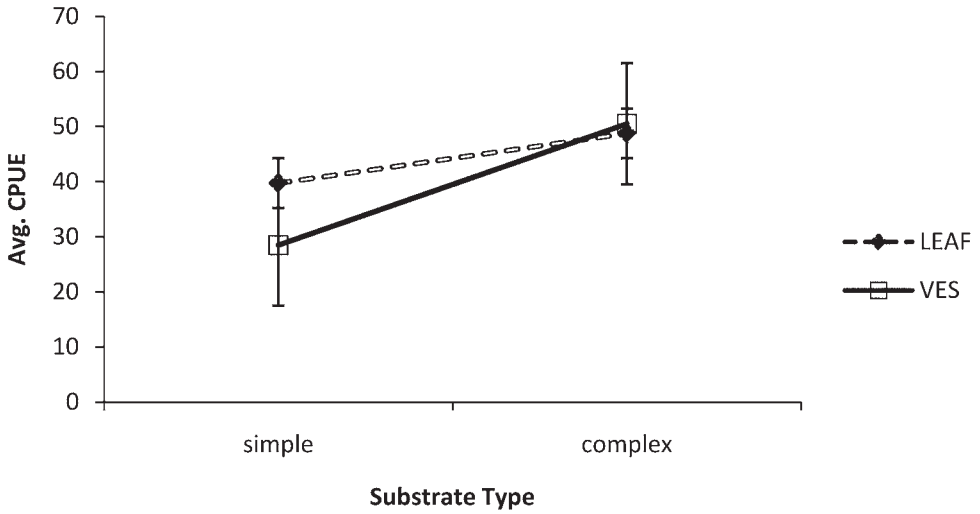

FIG. 1. Average catch-per-unit-effort (CPUE) using leaf litter bags (LEAF) and visual encounter surveys (VES) in simple and complex substrates.

Acknowledgments.—We thank J. Costa for permission to sample streams. Support for this project was provided by the Highlands Biological Station Fellowship. Salamanders were collected under North Carolina Wildlife Resources Commission permit number 08-SC00329. All procedures used in the study were approved by the University of Missouri Animal Care and Use Committee.

A Functional and Cleanable Substrate for Snake Testing Arenas

KERRY A. HANSKNECHT*

When studying snake behavior in experimental arenas, several considerations must be made when choosing an appropriate substrate. Because of the importance of olfactory information to snakes, and because of their high sensitivity to chemical cues, we often desire an ability to control or eliminate odors in the experimental setting (Ford and Burghardt 1993). This, and the occasional need to reduce unwanted exploratory behaviors such as burrowing, often precludes the use of naturalistic litter substrates. Instead, we opt for a floor surface that is easy to clean or, in the case of paper

substrate, can be discarded and replaced. Many snakes rely heavily on lateral undulation for locomotion (Gans 1986; Gray 1946), which requires a substrate with considerable texture, and the use of smooth, easily cleaned or disposable substrates limits this ability. In experimental arenas with such substrates, snakes often use alternatives to lateral undulation (e.g., concertina and rectilinear motion; Gans 1986; Gray 1946) that may be perfectly acceptable or appropriate depending on the conditions of the study. However, concertina locomotion is apparently far less efficient than lateral undulation (Walton et al. 1990), and under some circumstances the relatively low rate of travel achieved by concertina or rectilinear locomotion can be counterproductive to behavioral studies. Snakes and other legless squamates will also resort to slide-pushing when other methods prove ineffective (Gans 1984; Gasc and Gans 1990), and this often involves vigorous movements of the entire body that might detract from a subject's ability to attend to stimuli important to a given experiment.

Researchers have found alternatives to paper or smooth flooring, such as artificial turf or indoor-outdoor carpeting (Finkler and Claussen 1999; Winne and Hopkins 2006). These provide more texture than many paper substrates and are resilient enough to be washed and reused many times. However, the labor and time required to thoroughly wash and let dry the large number of carpet pieces required to conduct numerous experimental trials seems hardly worth the small improvement in snake locomotion obtained by using these as substrates, particularly the latter (personal observation). Because of this, we have sought and found what we believe to be a better solution.

Perlite is a lightweight, crumb-like material having many applications, the most familiar perhaps being its use as an incubation substrate for reptile eggs and to improve aeration of soils for gardening. It is readily and inexpensively available at garden supply stores worldwide. Another use of perlite, and the one that led to its use here, is as an additive to paints to provide visually pleasing texture to the ceilings and walls in our homes. When sold as a paint texturizer, perlite can have a fine, medium, or coarse grain. By mixing a coarse perlite with animal-safe paint, applying this mixture to an arena floor, and then coating it with several additional paint-only layers, we have obtained a substrate that is easy to clean thoroughly (we wash it with warm soapy water, rinse, and then finish with a microfiber cloth dampened with isopropanol), dries quickly afterward, and is resilient to frequent cleaning. The substrate remains fixed and weighs very little, allowing one to keep the test arena highly portable if desired. During the first few cleanings, a small number of the perlite pieces might become broken or dislodged, but this soon ceases after recoating with paint. The treatment is extremely easy to apply, and it can be used on surfaces of any size, shape, or orientation. Moreover, one can vary the location, amount, and coarseness of texture to suit specific needs. Vermiculite, which is very similar to perlite, is also likely to function well for this purpose, though its more angular nature might inhibit satisfactory paint coverage.

Although we have not empirically tested for effects of this treatment on the chemosensory behavior of snakes, we have noticed no aversive responses (e.g., tongue flicks followed by abrupt evasive motions) from any study subjects in arenas treated in this manner. However, in order to limit the possibility of adverse paint-related chemical effects, all new applications of paint should be subjected

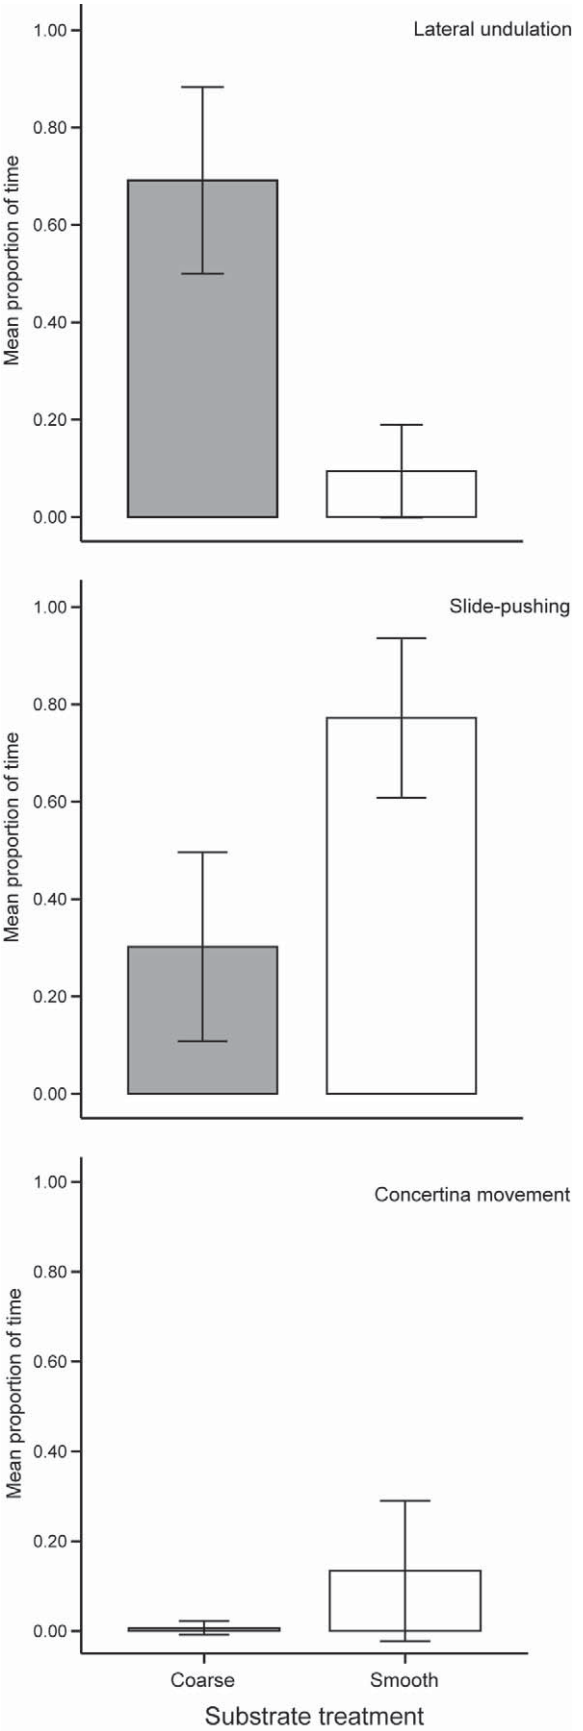

FIG. 1. Mean proportions of time spent by 10 *Nerodia clarkii compressicauda* engaging in three locomotory methods on a smooth painted surface (smooth) and on a surface treated with perlite-infused paint (coarse). Error bars indicate 95% confidence intervals.

to several cycles of washing and drying before use. Furthermore, by preparing arenas well in advance, at least twice the suggested curing time of the paint, one can thoroughly wash newly treated arenas several times as soon as the paint has been allowed to dry for the suggested length of time, dislodging any fragile or poorly anchored pieces of perlite in the process, and still have time to recoat the surface and allow the paint to properly cure prior to experimentation.

In an examination of this substrate's effect on snake locomotion, we observed 10 Mangrove Saltmarsh Watersnakes (*Nerodia clarkii compressicauda*; mean SVL = 21.3 cm) traversing each of two wooden-floored, 13 x 60 cm trackways, one treated in the manner described above (the coarse treatment) and one treated with only paint (the smooth treatment). Data for each subject were the proportions of time spent using lateral undulation, concertina movement, and slide-pushing (the only three locomotory modes we observed), averaged over three trials in each of the two treatments. The proportions of time spent engaged in lateral undulation (Wilcoxon Signed Ranks Test; $Z = 2.67$; $p = 0.008$), slide-pushing (Wilcoxon Signed Ranks Test; $Z = 2.67$; $p = 0.008$) and concertina movement (Wilcoxon Signed Ranks Test; $Z = 2.20$; $p = 0.028$) differed significantly between the coarse and smooth surface treatments (Fig. 1). Subjects primarily used lateral undulation on the coarse surface and slide-pushing and concertina movement on the smooth surface. Thus, the perlite treatment provides a texture that facilitates the use of lateral undulation better than does a surface treated only with paint. In addition to tests involving snakes on dry arena floors, the painted perlite substrate has proved beneficial in experiments involving snakes in shallow-water test arenas and in a study involving terrestrial monitor lizards. Studies involving other squamates, legless or otherwise, may also benefit from such a substrate when more naturalistic materials are not feasible.

Acknowledgments.—We thank Gordon M. Burghardt for helpful comments on this manuscript and for feedback after using this substrate for experiments with monitor lizards. Research related to this article was conducted in compliance with protocols approved by the University of Tennessee IACUC.

Although a substantial proportion of North American frogs and toads will use burrows facultatively, as retreats from stressful environmental conditions (typically cold and/or dry weather; Lannoo et al. 2005; individual species accounts in Lannoo 2005), a handful of species use borrows obligately—relying on them to meet physiological or ecological needs. The Nenirana group of Hillis and Wilcox (2005) contains three species, *Lithobates areolatus* (Crawfish Frogs), *L. capito* (Gopher Frogs), and *L. sevosus* (Dusky Gopher Frogs) that inhabit burrows constructed by other species (predominantly crayfish in the case of *L. areolata*, and Gopher Tortoises [*Gopherus polyphemus*] in the case of *L. capito* and *L. sevosus*, though they are also known to inhabit small mammal burrows and holes in dead or rotting trees; Lannoo 2005). Adults of these three species are secretive and rapidly retreat into burrows when disturbed. Therefore, outside of the breeding season these frogs are rarely seen, and when seen near burrows (as they almost always are) they are next to impossible to capture. All three species are of conservation concern (Jensen and Richter 2005; Parris and Redmer 2005; Richter and Jensen 2005); *L. sevosus* is known from only two populations and is listed as federally endangered (USFWS 2001).

If we are to gather the basic ecological information needed to conserve these species, we must develop techniques for capturing animals year-round, through all life history stages. Once captured, animals can be weighed and measured, assessed for health, marked, and implanted with radiotransmitters. The best techniques for capturing animals retain the integrity of the burrow, because animals are known to use the same burrow throughout the warm season (Richter et al. 2001; JLH, unpubl. data) and perhaps longer. Further, it has been suggested that burrows are a limiting resource (Thompson 1915; Jensen and Richter 2005).

We developed a technique to capture Crawfish Frogs from their burrows, but the technique can be applied to Gopher Frogs and other animals occupying small-diameter burrows. We work on Crawfish Frogs in southwestern Indiana; *L. areolatus* is classified as state endangered in Indiana. Crawfish Frogs spend the majority of their adult lives associated with upland burrows, primarily those created by crayfish. Several different species of crayfish construct suitable burrows; at our study site in southwestern Indiana there are *Cambarus diogenes*, *Fallicambarus fodiens*, and *Cambarus* (*Tubericambarus*) *polychromatus* (Thoma and Armitage 2008). Crayfish burrows extend from the soil surface down to the water

table, and while chambers and side passages may be common, crayfish burrows are not usually a part of a vast burrow network. Burrows tend to be in clay soils, which create well-defined burrow walls and retain water (Grow and Merchant 1980). Compared with Gopher Tortoise burrows, crayfish burrows are narrow; burrows used by Crawfish Frogs are typically not much wider at the surface than the frog itself.

It follows that methods used to extract crayfish from burrows would be effective at extracting Crawfish Frogs. Published methods of successful crayfish extraction include excavation of burrows (Simon 2001), Norrocky pipe traps (Norrocky 1984), plungers (Simon 2001), motorized pumps (Thoma and Armitage 2008), and burrowing crayfish mist nests (Welch and Eversole 2006). However, several of these methods (excavation, plungers, pumps, and pipe traps) permanently damage burrows and the surrounding area (Ridge et al. 2008), and they all could potentially stress or injure the frog.

In addition to considering the above techniques, we tried securing a collapsible mesh minnow trap over the crayfish burrow. We also tried inserting a piece of PVC pipe at the burrow entrance with the idea that once the frog entered we would remove and cover the burrow end of the pipe (with a spatula) to trap the frog. We tried putting mist netting outside the burrow (similar to the Welch and Eversole [2006] crayfish net) as well as putting variations of a trap door over the burrow opening. Though occasionally successful, all of these methods turned out to be less than ideal for the capture of Crawfish Frogs. The success of some traps (minnow traps and PVC pipe traps) was limited because they did not prevent animals from returning to their burrows and all traps required constant monitoring, potentially for several days, while waiting for the frog to emerge from the burrow.

We were compelled to find a technique that would induce animals to leave their burrows while we were present, and would prevent them from returning to burrows once they were aware of our presence. The key observation (JLH) was that following heavy rains and burrow flooding, Crawfish Frogs surface every 20–40 min to breathe. The technique we introduce here has two basic components: flooding burrows to induce animals to surface, and blocking their retreat with an inflated balloon.

We outfitted a bicycle tire pump with a long (> 2 m) plastic tube (8 mm diameter) and attached a circular-shaped balloon to the end with a rubber band, so that when the bike pump handle was depressed, the balloon inflated (Fig. 1A, B). When inflated, the balloon conforms to the interior contours of the burrow but does not alter the burrow itself. To capture frogs we inserted the deflated balloon into the burrow (~20–30 cm). We then filled the burrow from a 23-liter jug containing water from a nearby lake. It usually took about 12 liters of water to fill burrows, and more water to maintain the water level at the surface of the burrow. Crawfish Frogs take an average of 30 min to surface. When they surface, we inflate the balloon, trapping the frog at the burrow entrance. In response, the frogs typically inflate their bodies and lower their head, tucking their jaws towards their chest. To extract them we gently pull up on the tubing and the balloon, forcing the frog out. For stubborn frogs, we insert a spatula and gently pry them out. This technique does not damage the burrow when done carefully, and we do not use enough force to harm the frog. The vegetation around the burrows gets trampled but recovers. Some frogs come

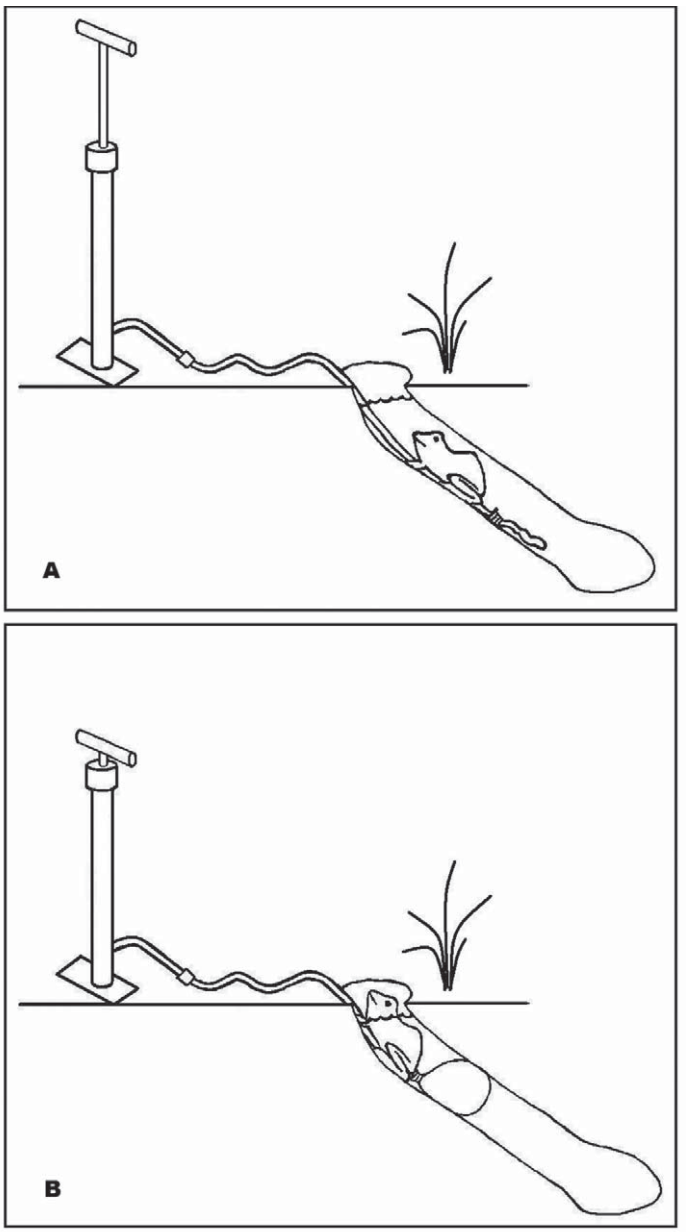

FIG. 1. A) Crawfish Frog in burrow below water surface, balloon deflated, tire pump plunger up. B) Crawfish Frog rises to water surface, balloon inflated, tire pump plunger down.

up for air and quickly escape back into the burrow before the balloon can be inflated. In these cases, we repeat the procedure. On a few occasions the balloon ruptured.

This method was also successful for retrieval of a Southern Leopard Frog (*Lithobates sphenocephalus*), but it took the frog about 165 minutes to surface. In addition to applying this technique to burrows known to be occupied (most of our known burrow sites were discovered following the implantation of their inhabitants with transmitters (3.8g PD-2 temperature sensing transmitters Holohil Systems Ltd. [Carp, Ontario, Canada]), we have also used this technique with success to determine the occupancy of suspected Crawfish Frog burrows (JLH, unpubl. data). The one time this technique did not work on a burrow known to be inhabited by a Crawfish Frog, the burrow branched uphill and therefore could not be sufficiently filled with water to force the

frog to surface. We suspect a modification of this technique could be used to extract Gopher Frogs and Dusky Gopher Frogs from Gopher Tortoise burrows, small mammal burrows, and other small refugia situated in clay substrates. This technique may be also applied to other amphibian species and perhaps to reptiles and other burrow-dwelling taxa.

Acknowledgments.—This research was conducted under IACUC number 3-24-2008 issued by Indiana State University, and Scientific Purposes License Permit number 09-0084 issued by the Indiana Department of Natural Resources. This project was funded by a U.S. Fish and Wildlife Service State Wildlife Grant, contract number E2-08-WDS13. Special thanks to Katie Smith and Ron Ronk, Indiana Department of Natural Resources, for enabling this project.

The pathogenic chytrid fungus, *Batrachochytrium dendrobatidis* (*Bd*), has been associated with population declines of many amphibian species around the world, including relatively pristine habitats (e.g., Berger et al. 1999; Fellers et al. 2001; Herrera et al. 2005; Skerratt et al. 2007; Lips et al. 2008; Wake and Vredenburg 2008). Chytridiomycosis, the disease induced by *Bd*, likely is the proximate cause of many of these declines (Lips et al. 2006; Rachowicz et al. 2006; Skerratt et al. 2007). While the foci of much current research, we lack a clear understanding of the origin of *Bd*, its distribution and persistence, and the mechanisms by which it spreads across the landscape and ultimately kills amphibians (Longcore et al. 2007; Morgan et al. 2007; Lips et al. 2008; Wake and Vredenburg 2008), although Voyles et al. (2009) recently reported disruption of electrolyte transport and cardiac arrest as potential mechanisms for causing mortality.

Typically, vulnerable individuals die after *Bd* has infected their keratin, but vulnerability varies with life stage and species traits (Ouellet et al. 2005; Rollins-Smith and Conlon 2005; Longcore et al. 2007; Morgan et al. 2007; Bielby et al. 2008; Harris et al. 2009). Some species, such as the African Clawed Frog (*Xenopus laevis*) and American Bullfrog (*Rana catesbeiana*), are known to carry *Bd* without symptoms of the disease whereas diseased individuals have been observed in populations of other species without associated die-offs (Ouellet et al. 2005; Corn 2007; Kriger and Hero 2006; Longcore et al. 2007). As a fundamental first step in understanding these ecological processes and the resultant threats *Bd* poses to amphibian populations in specific areas, we need to know whether populations are exposed to the pathogen (e.g., Retallick et al. 2004; Ouellet et al. 2005; Pearl et al. 2007; Frias-Alvarez et al. 2008). We report here on results of our efforts to produce baseline data on *Bd* detection in US states for which few data have been reported: Minnesota, Wisconsin, and Iowa (Loda and Otis 2009).

We sampled recently metamorphosed amphibians at 75 unique breeding sites across five general areas within the north-central US: 1) Voyageurs National Park, 2) the St. Croix National Scenic Riverway, 3) the Upper Mississippi River National Wildlife and Fish Refuge, 4) northern Iowa, and 5) southwestern Wisconsin

(Fig. 1). We sampled 29 sites during July and August 2006 and 64 sites during June, July, and August 2007, including 18 sites in both years (Table 1). We chose sampling locations based upon our knowledge of species occurrences at these sites gained during previous studies.

We sampled nine amphibian species, including *Bufo americanus*, *Acris crepitans*, the *Hyla chrysoscelis-versicolor* complex, *Pseudacris triseriata*, *R. catesbeiana*, *R. clamitans*, *R. septentrionalis*, *R. pipiens*, and *R. sylvatica* (Table 1). Our goal was to sample 20 live, apparently healthy recent metamorphs of each species available per site in 2006 and 30 such metamorphs in 2007. We sampled fewer metamorphs when we captured fewer animals than expected at a site (Table 1). Metamorphs were collected individually by hand capture or net during visual-encounter surveys in littoral or nearby habitat. We only sampled metamorphs with fully resorbed tails. Once captured and swabbed, we retained individuals until we completed all sampling at a site, at which time we released them near the point of capture. We sampled metamorphs of as many species as were available at each site during our sampling windows in a given year.

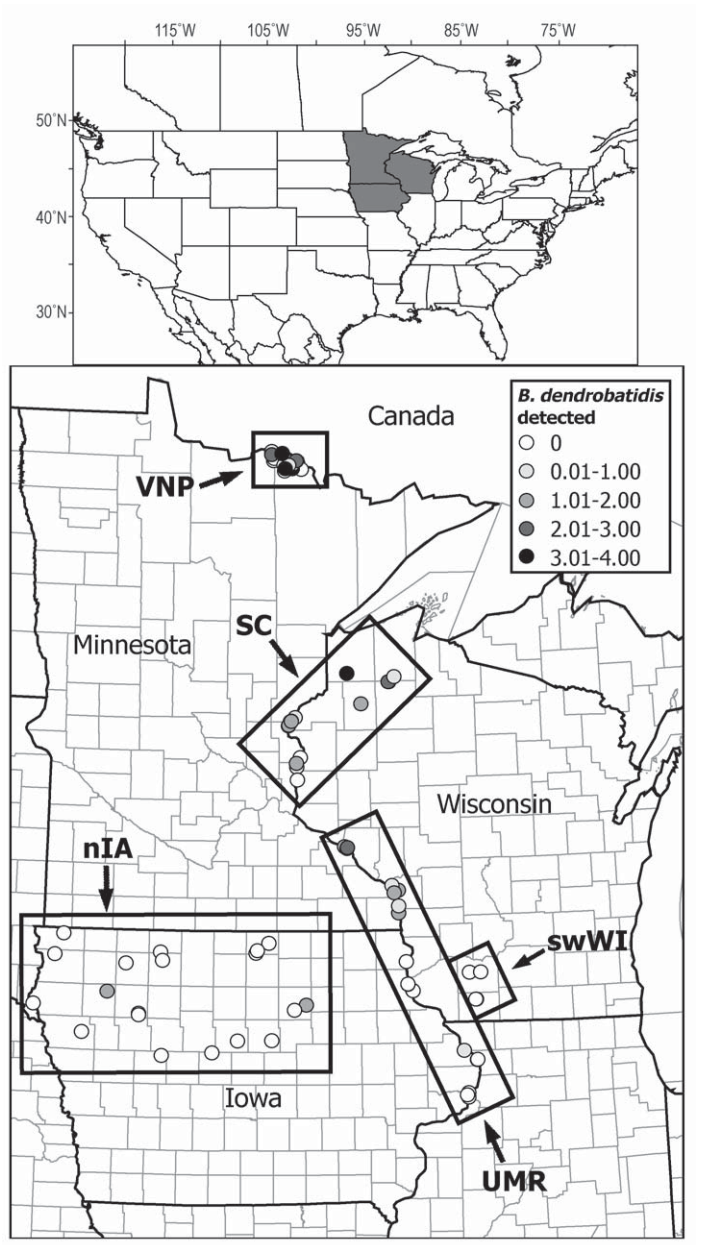

FIG. 1. The locations sampled in the north-central United States and relative quantities of *Batrachochytrium dendrobatidis* (*Bd*) detected across amphibian breeding sites and areas. Quantities are averages across species and years for each site based upon samples scored as 0 = not detected, 1 = weak positive signal, 2 = positive signal, 3 = strong positive signal, and 4 = very strong positive signal, as reported to us by Pisces Molecular LLC. Note that some breeding sites are not easily visible due to overlap at this scale. VNP = Voyageurs National Park; SC = the St. Croix National Scenic Riverway; UMR = the Upper Mississippi River National Wildlife and Fish Refuge; swWI = southwestern Wisconsin; nIA = northern Iowa.

We used decontaminated equipment and fresh disposable gloves to capture and handle each individual specimen and one cotton-tipped swab (Puritan brand, 15 cm, no-glue cleaning sticks) to swab each animal 30 times across the ventral skin on the thighs, abdomen, and hind limbs, including the interdigital webbing, similar to Livo (2004). Typically, we pooled the ten individual cotton-tipped swabs we used to sample ten individual conspecific metamorphs at each site in one sterile vial containing 70% EtOH. This enabled us to limit analytical costs (two samples of pooled swabs per species per site in 2006 and three in 2007) while increasing our chances of detecting *Bd* within a sample simply due to more animals represented in each sample analyzed. We sealed vials on site and sent them to Pisces Molecular LLC (Boulder, Colorado) for PCR analyses as per their instructions. Pisces Molecular LLC used methods described in Annis et al. (2004) and reported results to us as not detected, weak positive signal, positive signal, strong positive signal, or very strong positive signal. According to Pisces Molecular LLC, the detection limit was 0.1 zoospore equivalent DNA per PCR reaction.

Bd was detected on at least one species at 34 of 75 sites (45%) and in 4 of the 5 general areas sampled (Table 1; Fig. 1). *Bd* was detected most often on *R. clamitans* (23 of 27 sites) and *R. septentrionalis* (7 of 9 sites) in relatively moderate to heavy quantities. The remaining detections also were on ranids, in relatively small quantities on *R. pipiens* (5 of 39 sites) and *R. sylvatica* (6 of 9 sites) and in moderate quantities on *R. catesbeiana* (1 of 2 sites). *Bd* was not detected on *B. americanus*, *A. crepitans*, *H. chrysoscelis/versicolor*, and *P. triseriata* (Table 1).

We sampled *R. clamitans* and *R. pipiens* at 11 of the same sites in 2007. *Bd* was detected on *R. clamitans*, but not *R. pipiens*, at six of those sites, and on both species at one other. *Bd* was not detected on either species at the remaining four sites (Table 1).

Our results provide the first baseline information we know of on the detection of *Bd* at our study sites and add to the sparse published *Bd* data for the north-central U.S. (Green et al. 2002; Ouellet et al. 2005; Spatialepidemiology.net/Bd-Maps 2009; Loda and Otis 2009). Although detection varied with year, site, and species, our results are similar to the relatively widespread distribution and variable detection reported for other regions in the U.S. and around the world (Ouellet et al. 2005; Longcore et al. 2007; Pearl et al. 2007; Spatialepidemiology.net/Bd-Maps 2009; Loda and Otis 2009). Our results also support previously reported observations that *Bd* detection can be a function of the species sampled (e.g., Retallick et al. 2004; Ouellet et al. 2005; Longcore et al. 2007; Pearl et al. 2007).

Other researchers have demonstrated *Bd* detection was greater

TABLE 1. Relative quantities of *Batrachochytrium dendrobatidis* (*Bd*) detected on swabs of recent metamorphs by species, year, area, and site in the north-central United States. Ac = *Acris crepitans*, Rcl = *Rana clamitans*, Rp = *R. pipiens*, Rse = *R. septentrionalis*, Ba = *Bufo americanus*, Hc/v = *Hyla chrysoscelis—versicolor* complex, Pt = *Pseudacris triseriata*, Rca = *R. catesbeiana*, and Rsy = *R. sylvatica*. Each number represents the relative quantity of *Bd* DNA detected in the extracts from ten pooled swabs (one swab per individual), unless noted as a different pooled number of swabs via a superscripted number in parentheses. 0 = not detected, 1 = weak positive signal, 2 = positive signal, 3 = strong positive signal, and 4 = very strong positive signal, as reported to us by Pisces Analytical LLC. These different signal strengths represent different relative quantities of *Bd* DNA present in samples (based upon comparisons of results using the 45-cycle, single-round, PCR amplification method used here with results from quantitative PCR; J. Wood, Pisces Molecular LLC; pers. comm.). VNP = Voyageurs National Park; SC = the St. Croix National Scenic Riverway; UMR = the Upper Mississippi River National Wildlife and Fish Refuge; swWI = southwestern Wisconsin; nIA = northern Iowa.

on more aquatic species, including several of the species we sampled (e.g., Retallick et al. 2004; Ouellet et al. 2005; Longcore et al. 2007; Pearl et al. 2007). For example, we did not detect *Bd* in relatively small samples of *B. americanus*, *H. chrysoscelis/versicolor*, *P. triseriata*, and *A. crepitans* and we detected it infrequently on *R. pipiens*. These results were similar to those from previous studies showing lower detections or infections in these less-aquatic species (Ouellet et al. 2005; Longcore et al. 2007). As possible further support for such observations, we also detected *Bd* less often on *R. pipiens* than on *R. clamitans* sampled from the same sites. Rollins-Smith and Conlon (2005) demonstrated that *R. pipiens* produces skin peptides that confer *Bd* resistance. This might or might not have affected our detections of *Bd* on *R. pipiens* in this study. Our detections of *Bd* on the largely terrestrial *R. sylvatica* from six of nine sites ran counter to the trend of lower detections on less aquatic species and is a higher frequency than reported previously for this species (Ouellet et al. 2005; Longcore et al. 2007; Reeves 2008). All told, because of variance in detection among species, limited sample sizes, and because we were not able to sample species with apparent higher detection rates, such as *R. clamitans* or *R. septentrionalis*, across all sites, we cannot conclude *Bd* was not present at sites where

we did not detect it. This is especially true for northern Iowa, where we sampled only *A. crepitans* and *R. pipiens* at 18 of the 19 sites, and southwestern Wisconsin, where we sampled only *A. crepitans* at all four sites.

We have conducted call and/or visual-encounter surveys at these breeding sites and many others since 2002 as part of the U.S. Geological Survey's Amphibian Research and Monitoring Initiative (ARMI) in ARMI's Midwest Region. While we cannot speak to trends in the demographics of any of these populations or breeding subpopulations, we observed most of the species we expected to be present during our surveys. An exception has been *A. crepitans*, which we did not observe at many potential breeding sites and is known to have declined throughout the northern portion of its range, including much of the area in Iowa we report on here. In addition to observing most of the expected species, we rarely have observed dead postmetamorphic amphibians, although this is not unusual in association with chytridiomycosis (Skerratt et al. 2007). *Rana clamitans* and *R. septentrionalis* from four of the Voyageurs sites we report on here had clinical chytridiomycosis in previous years (D. E. Green, pers. comm.), but we did not observe live animals displaying any behavioral symptoms of chytridiomycosis (Berger et al. 1999) at these sites or elsewhere. Thus, based upon all of our observations, we have no evidence of dramatic recent population declines associated with any of these *Bd* detections, similar to what others have stated for other regions (e.g., Longcore et al. 2007). Clearly, however, we lack a substantive understanding of amphibian population dynamics in relation to *Bd* presence and chytridiomycosis at these sites to comment on this meaningfully. More intensive studies are necessary to understand any impacts of *Bd* exposure on amphibian populations in this region.

Acknowledgments.—We thank the U.S. Geological Survey's Amphibian Research and Monitoring Initiative for financial support, Erik Latremore, Vanessa Keller, Rick Purcell, Kim Schuster, Breann Sommer, Katie Stinebrink, Rori Paloski, and Tara Bergeson for assistance in the field, and the U.S. National Park Service, U.S. Fish and Wildlife Service, the Natural Resources Conservation Service, and the Iowa and Wisconsin Departments of Natural Resources for support via appropriate permits and agreements. All animals were handled in compliance with approval provided us by the Animal Care and Use Committee at the Upper Midwest Environmental Sciences Center.

Amphibian chytrid fungus (*Batrachochytrium dendrobatidis*, hereafter *Bd*) has been documented in a variety of species and habitats across North America, although the full extent of its faunal and geographic distribution is not yet known (Adams et al. 2007; Briggler et al. 2008; Longcore et al. 2007; Ouellet et al. 2005; Pearl et al. 2007; Reeves and Green 2006). To our knowledge, no surveys for the presence of this fungal pathogen have been published on cave amphibian populations. Missouri contains 6200 caves and 927 documented species (Elliott 2007) with eight amphibian species commonly inhabiting Ozark caves and one salamander that is cave restricted (Sutton 1993). The goal of this study was to test for the presence of *Bd* among multiple amphibian taxa found in caves across the lower Missouri Ozarks.

From November 2007 to October 2008 we tested 35 adult and larval amphibians from 12 caves in 5 counties in the Missouri Ozarks for *Bd*. Adults and some larvae were tested for *Bd* by swabbing a cotton-tipped wooden shaft applicator over the ventral surface of each foot, the back, the abdomen, and around the thigh and vent area. The wooden tip end of the applicator was first lightly rubbed on these surfaces followed by the cotton end of the applicator. Both wooden and cotton tip were broken off and placed in a 2.0 ml screw-cap tube with 1 ml of 70% ethanol. Larval salamanders that were too small to swab effectively were collected and placed in a 2.0-ml screw-cap tube with 1 ml of 70% ethanol. All samples were shipped to Pisces Molecular, Boulder, Colorado, for PCR (polymerase chain reaction) assay.

Of the 35 individuals sampled in this study, 11 were infected with *Bd*. Positive *Bd* test results were detected from at least one cave in all 5 counties tested (Fig. 1; Table 1). Adult animals comprised the bulk of our sampling (29 of 35 individuals sampled). Ten adult samples showed positive *Bd* test results. Of the six larval salamander samples collected, one larval *Eurycea spelaea* (Grotto Salamander) tested positive for *Bd*, which is of interest as there are few documented cases of *Bd* in larval salamanders (Brodman and Briggler 2008). Although we tested both salamander and anuran species for *Bd*, more salamander species were tested and *Bd* was more prevalent among anurans; 20% of anurans tested positive for *Bd* while only 11.4% of salamanders tested positive ($\chi^2 = 9.37$; df = 1; P = 0.002). *Bd* samples were collected from amphibians classified as trogloxenes (species that use caves but cannot complete their life cycle entirely within a cave), troglophiles (species that can complete their life cycle within a cave but are also widely seen above ground), and troglobites (species that are cave obligates) (Table 1). The majority of samples were collected from troglophiles (60.0%); trogloxenes, which comprised 25.0% of our samples, showed the highest percent of *Bd* infection (17.1%), followed by troglophiles (11.4%) and troglodytes (2.9%).

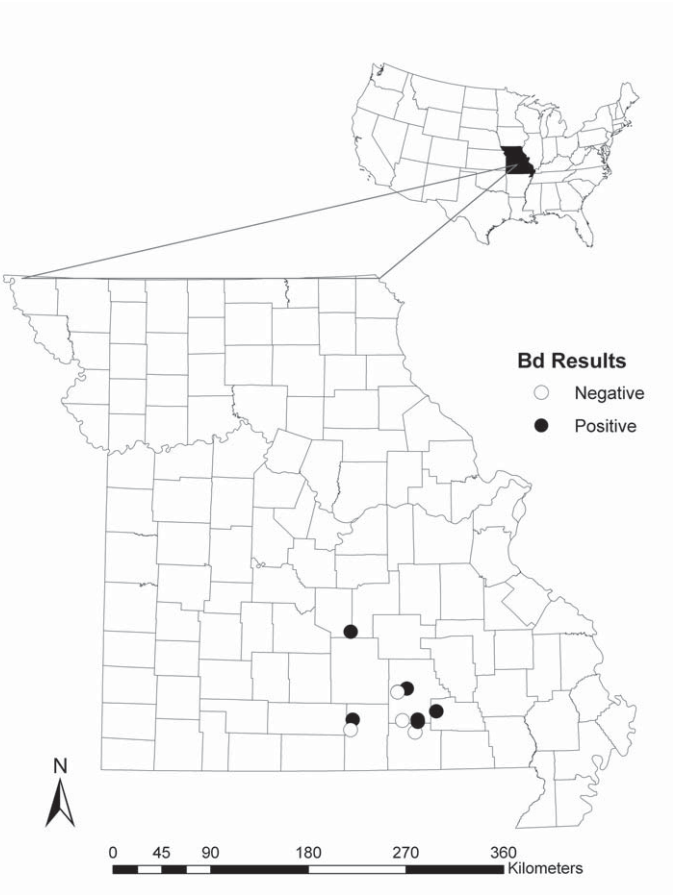

FIG. 1. Cave locations surveyed for *Batrachochytrium dendrobatidis* (*Bd*). Open circles indicate caves where all samples were negative for *Bd*, while closed circles indicate caves that had at least one positive *Bd* test. Proximity of caves led to overlap of symbols for three locations.

Bd grows and reproduces at temperatures of 4–25ºC with maximal growth at 17–25ºC (Piotrowski et al. 2004). The thermal environment of the Ozark caves in this study, while not ideal, is suitable for *Bd* growth with average water temperatures of 11.6ºC.

In this study, anurans were infected with *Bd* in higher proportions than were salamanders, although our relatively modest sample size may not accurately reflect *Bd* prevalence. *Lithobates palustris*, which comprised the bulk of our anuran *Bd* samples, typically seek caves for refuge from hot weather during summer and from cold temperatures during winter, exiting for periods to breed and feed

(Johnson 2000; Prather and Briggler 2001; Resetarits 1986). This life history trait may help to explain the prevalence of *Bd* among the anurans in our samples and also to explain a possible transport mechanism of *Bd* in cave systems. Similarly, trogloxenes had the highest overall rates of *Bd* infection is this study when compared to troglophiles and troglodytes. As with *Lithobates palustris*, which is a trogloxene ecotype, trogloxene species tend to be very mobile and will spend a large amount of time outside of the cave during different life stages or seasons (Briggler and Prather 2006; Mittleman 1950; Petranka 1998). This behavior may serve to move *Bd* into, out of, and among different caves. However, in the Lower Missouri Ozarks, streams, creeks, caves, and springs in watersheds are connected by a system of karst (Elliott 2005) and presence of *Bd* among aquatic hellbenders throughout the Ozarks (Briggler et al. 2008) has been well documented. The karst system itself also may be serving as a conduit to spread *Bd* throughout watersheds and among caves throughout this region.

Acknowledgments.— This work was funded by the Missouri Department of Conservation. We thank J. Wood from Pisces Molecular, Boulder, Colorado, for analyzing the *Bd* samples. We also thank C. Benda, D. Dreese, L. Hughes, S. Paes, and T. Thompson for assistance in the field. Thanks to D. Butler for assistance with graphics. Special thanks to B. Elliott of the Missouri Department of Conservation and S. House of the Cave Research Foundation. Research was conducted in compliance with applicable animal

care guidelines and appropriate permits were obtained.

Viruses in the genus *Ranavirus* are implicated as a possible contributing factor to global amphibian declines (Daszak et al. 1999). Previous studies have associated ranaviruses with mass amphibian die–offs throughout North America (Chinchar 2002 Greer et al. 2005; Williams et al. 2005) including Minnesota, USA (Green et al. 2002; Vandenlangenberg et al. 2003). However, it is unclear whether ranavirus infections exist in wild anuran populations without causing die-offs. This study investigates the presence of ranavirus in six anuran species at the headwaters of the Mississippi River in Itasca State Park, Minnesota, USA.

Methods.—We collected recently metamorphosed and adult frogs and toads by hand and with nets from twenty-six sites in Itasca State Park, Clearwater County, Minnesota (47.2397°N, 95.2075°W) in June and July 2009. Sites were chosen for maximum species diversity and for accessibility. There have been no reports of mass amphibian die-offs in the park, which has been the site of a University of Minnesota field station since 1909 (D. Biesboer, pers. comm., 30 July 2009; C. Handrick, pers. comm., 3 Aug 2009). Both field-based and lab-based courses are taught during summer months and there are few places in the state that have had such a consistent and thorough presence of biologists during peak periods of amphibian activity. This steady stream of students and faculty provides some level of confidence that amphibian die-offs will be observed and reported. That said, there is no guarantee that amphibian die-offs, particularly of aquatic larvae, went unobserved.

To minimize contamination among sites, nets and waders were rinsed with 5% bleach solution between collecting events. Captured frogs were kept individually in separate plastic bags. Individuals were classified as either young-of-the-year (YOY) or adults by comparing their snout-vent length to published sizes of adult frogs (Oldfield and Moriarty 1994; Wright and Wright 1995). Frogs were returned to the laboratory and humanely euthanized with MS-222 (tricaine methanesulfonate) (Simmons 2002). Liver samples were stored in RNAlater (Ambion, Austin, Texas, USA) or 99% ethanol at 4°C until processing. Vouchers were deposited in the Bell Museum of Natural History, University of Minnesota (JFBM).

We used disposable razor blades to subsample between 15–30 mg of liver tissues for DNA extraction using the Qiagen DNeasy Blood and Tissue Kit (Qiagen, Valencia, California, USA) follow-

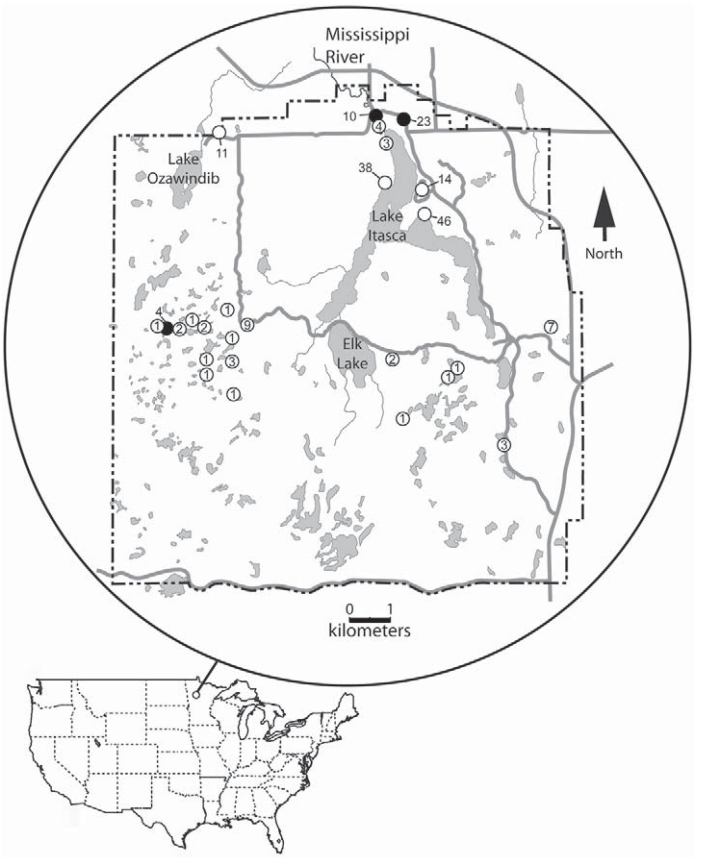

FIG. 1. Collecting locations (circles) of anurans screened for ranavirus at Itasca State Park, Minnesota, USA. Numbers reflect sample size at each site. Sites with ranavirus positive specimens indicated by filled circles, localities with no ranavirus positive specimens indicated by open circles. Park boundaries shown by a dashed line. Light gray areas are water.

ing the manufacturer's protocol. We screened DNA for the presence of ranavirus using polymerase chain reaction (PCR) to amplify a highly conserved ~500-bp fragment of the ranavirus major capsid protein (MCP) using the MCP4 and MCP5 primers (Mao et al. 1997). PCR was carried out in 12.5 μl volumes using conditions described by Greer et al. (2005) and the product visualized by gel electrophoresis on 1% agarose gels stained with ethidium bromide. We ran negative (water in place of genomic DNA) and positive controls (DNA extracted from a specimen verified to be ranavirus positive) with each PCR reaction.

All positive samples were verified by sequencing using Big Dye terminator cycle sequencing on an ABI 3730xl at the Advanced Genetic Analysis Center, University of Minnesota. Sequences were identified as ranavirus using BLAST (Altschul et al. 1990). We gel-purified the positive PCR product from *L. pipiens* prior to sequencing using 3% agarose due to the presence of some non-specific PCR products. Positive PCR products of *L. sylvatica* were purified using Exonuclease I and Shrimp Alkaline Phosphatase (Hanke and Wink 1994).

Results.—We collected and tested 191 YOY and adult frogs of six different species. Four individuals (2%) from two species tested positive for ranavirus (Table 1): three *Lithobates sylvatica* (JFBM 16793, 16923, and 17116) and one *Lithobates pipiens* (JFBM 16932). Four frog species, *Lithobates septentrionalis*, *Pseudacris crucifer*, *Hyla versicolor*, and *Anaxyrus americanus*, had no positive samples. We captured infected frogs from three different sites within Itasca State Park (Fig. 1); the infected *L. pipiens* shared a site with one of the infected *L. sylvatica* (JFBM 17116). One *L. sylvatica* (JFBM 17116) and the infected *L. pipiens* were adults while the two remaining *L. sylvatica* were recent YOY. Aside from one dead ranavirus-negative *L. pipiens* (cause of death undetermined), all specimens appeared healthy at the time of capture.

DNA sequences (Genbank accession # GQ856477) from the four infected individuals were identical to each other and to other Frog Virus 3 (FV3) sequences from infected North American amphibians (Genbank FJ459783, GQ144408, FJ601916, AY548484, and U36913) and the *Terrapene* Virus 3 (TV3) sequence (U82553) from a turtle (Mao et al. 1997).

Discussion.—FV3 was originally isolated from a Northern Leopard Frog (*L. pipiens*) collected from Minnesota or Wisconsin, and proved to be fairly benign in metamorphosed amphibians in laboratory experiments (Granoff et al. 1966; Tweedell and Granoff, 1968; see Williams et al. 2005 for historical review), but since then, amphibian ranaviruses have been primarily associated with mortality events, especially in larval amphibians (Gray et al. 2009, but see Gray et al. 2007). The presence of ranavirus in apparently healthy metamorphosed frogs at Lake Itasca State Park, an area with no reported amphibian die-offs, suggests that die-offs may not be an inevitable outcome of ranavirus infections and that ranavirus may be more common than previously thought.

There are several possible explanations for our observations of ranavirus in the absence of large-scale mortality events. These include: genetic resistance in these anuran populations (Green et al. 2002; Pearman et al. 2004; Teacher et al. 2009); a less virulent strain of FV3-like virus; the absence of some environmental conditions necessary to cause mass die-offs (Gahl and Calhoun 2008; Greer et al. 2005); or that die-offs occurred but went unnoticed or unreported, particularly since mortality in early, aquatic life history stages would be difficult to observe.

TABLE 1. Ranavirus infections in six frog species collected in Itasca State Park, Minnesota, USA, in 2009.

Species	Family	Adults positive / tested	YOY positive / tested	All individuals positive / tested	Prevalence in all individuals (95% CI)
Lithobates sylvatica	Ranidae	1/21	2/47	3/68	4.4 (2.01–12.69)
Lithobates pipiens	Ranidae	1/68	—	1/68	1.5 (0.01–8.63)
Lithobates septentrionalis	Ranidae	0/27	—	0/27	0 (0–10.85)
Pseudacris crucifer	Hylidae	0/3	0/2	0/5	0 (0–40.10)
Hyla versicolor	Hylidae	0/7	0/2	0/9	0 (0–26.93)
Anaxyrus americanus	Bufonidae	0/3	0/11	0/14	0 (0–19.08)

Other studies have confirmed that five of the frog species we examined are susceptible to ranavirus (Duffus et al. 2008; Green et al. 2002). Although the susceptibility of *A. americanus* to ranavirus remains unknown, ranavirus has been identified in other bufonids such as *Anaxyrus fowleri*, *Bufo bufo*, and *Rhinella marina* (Chinchar 2002; Cunningham et al. 2007; Zupanovic et al. 1998). Given our small sample sizes and the potential for false negatives (Greer and Collins 2007), we cannot eliminate the possibility that species we identified as negative were also infected at low levels.

It is important to document the baseline prevalence of ranavirus infections in amphibian populations in order to understand its epidemiology and transmission in wild populations. In much of the ranavirus literature, amphibians are sampled and tested only after or during die-offs. While this response-based sampling is valuable, it offers a skewed estimate of ranavirus prevalence and perhaps virulence in amphibian populations. Future studies should expand the limited documentation of baseline ranavirus levels in randomly-sampled wild populations and also investigate the factors that may cause sublethal infections to become virulent. Such research would allow scientists to better evaluate the causes and consequences of ranavirus infections in amphibian communities.

Acknowledgments.—We thank the members of the Global Change Ecology program and the staff at the Itasca Biological Station for help with field work; Jesse Brunner and two anonymous reviewers for thoughtful comments on the manuscript; and Andrew Simons and Ken Kozak for access to laboratory space. Increasing Detections of *Batrachochytrium dendrobatidis* in Central Florida, USA

CAROL E. RIZKALLA
Department of Education & Science, Disney's Animal Kingdom
PO Box 10000, Lake Buena Vista, Florida 32830, USA
e-mail: Carol.X.Rizkalla.-ND@disney.com

The fungal pathogen *Batrachochytrium dendrobatidis* (*Bd*) was first detected in Florida, USA in 2008 in one American Bullfrog (*Lithobates catesbeianus*) and in one Florida Cricket Frog *(Acris gryllus dorsalis)* (Rizkalla 2009). Here, I report the results of further testing on 16 amphibian species in Walt Disney World's Wildlife Management and Conservation Area (WMCA) in central Florida.

The WMCA is a network of primarily forested wetlands with interspersed upland spanning 3380 ha in Orange and Osceola counties designed as a buffer area for Reedy Creek and managed by the Reedy Creek Improvement District. The Reedy Creek basin includes a significant portion of the headwaters of the Kissimmee River. Sampling for this study was restricted to the northern portion of the WMCA, centered approximately at 28.39929703°N, 81.60801927°W. A HOBO data logger (Onset Computer Corporation, Bourne, Massachusetts, USA) recorded weather conditions at approximately 28.398159°N, 81.597216°W. Amphibians were captured using plywood coverboards, minnow traps, and during incidental encounters. Thirty-four coverboard arrays were placed 250-m apart with each array checked once a month. Ten minnow traps were placed in canals, a marsh, and a pond for three days each month. Because the first positive bullfrog was found in an exhibit within Disney's Animal Kingdom® Theme Park, we also sampled native anurans found within the water features of many exhibits. Clean disposable gloves were worn when handling each animal.

As described in Rizkalla (2009), live amphibians were swabbed along the ventral surface and legs 25 times with cotton-tipped swabs (Puritan, Guilford, Maine, USA). Swab tips were stored at room temperature in 2-ml screw cap microcentrifuge tubes (Fisher #02-681-343) containing 1 ml of 70% ethanol. The keratinized regions around the mouths of six tadpoles found dead (American Bullfrog and Southern Leopard Frog, *L. sphenocephalus*) were also submitted for analysis. Sample collection occurred from July 2008 – July 2009. Maximum daily temperature during sample days ranged from 15.2–37.9°C. Samples were sent in August 2008, and June, August 2009 to Pisces Molecular (J. Wood, Boulder, Colorado, USA) for analysis using a polymerase chain reaction to detect *Bd* presence (Annis et al. 2004). For this report, 266 samples from 16 species were analyzed.

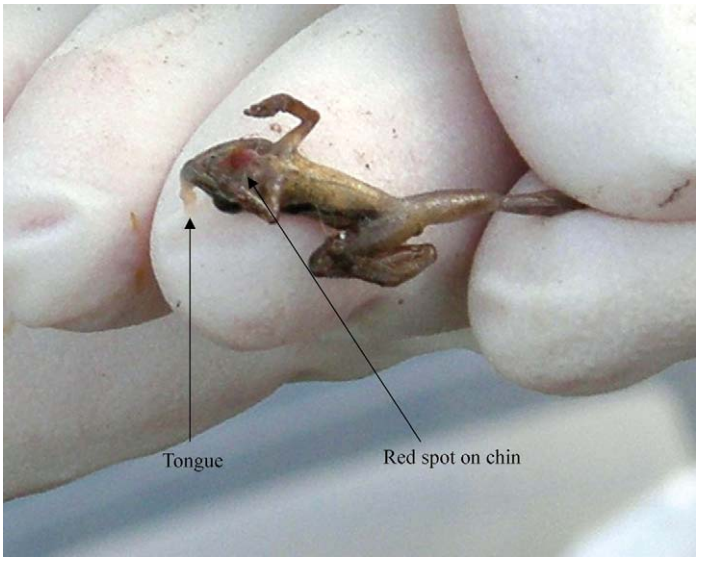

FIG. 1. Symptoms of *Batrachochytrium dendrobatidis* (*Bd*) in a Little Grass Frog (*Pseudacris ocularis*) included lethargy, loss of righting mechanism, a red spot on the chin (arrow), and inability to retract the tongue.

Several species were *Bd*-positive within the WMCA, including five Florida Cricket Frogs, three Greenhouse Frogs (*Eleutherodactylus planirostris*), two Southern Toads (*Anaxyrus terrestris*), and one Little Grass Frog (*Pseudacris ocularis*) (Table 1). Only the Little Grass Frog showed clinical signs of infection. When captured, it appeared lethargic, could not retract its tongue, and had a red spot on its chin (Fig. 1). When released upon swabbing, it did not right itself and died soon after. Infection was also detected in one adult American Bullfrog and one Cuban Treefrog (*Osteopilus septentrionalis*) found within Disney's Animal Kingdom®.

TABLE 1. Prevalence in 2008 (Rizkalla 2009), 2009, and total prevalence (no. animals testing positive/total sampled; "—" indicates none detected) of *Batrachochytrium dendrobatidis* on amphibians in Walt Disney World's Wildlife Management and Conservation Area, Florida, USA.

Species	2008	2009	Total Prevalence
Amphiuma means	0/1	0/1	0/2
Siren lacertina	—	0/4	0/4
Notophthalmus viridescens piaropicola	—	0/2	0/2
Eleutherodactylus planirostris	0/59	3/12	3/71
Anaxyrus terrestris	0/7	2/60	2/67
Acris gryllus dorsalis	1/5	5/70	6/75
Hyla cinerea	0/6	0/36	0/42
Hyla femoralis	—	0/6	0/6
Hyla squirella	—	0/1	0/1
Osteopilus septentrionalis	0/1	1/37	1/38
Pseudacris nigrita	—	0/4	0/4
Pseudacris ocularis	—	1/6	1/6
Gastrophryne carolinensis	—	0/2	0/2
Lithobates catesbeianus	1/2	1/5	2/7
Lithobates grylio	—	0/1	0/1
Lithobates sphenocephalus	—	0/19	0/19

Sample sizes in the previous study (Rizkalla 2009) were too low to assess prevalence. For the well-sampled species in this study (Cuban Treefrog, Florida Cricket Frog, Greenhouse Frog, Southern Toad), prevalence of *Bd* infection appeared low (2.6–8%) or absent (Green Tree Frog). Given the small sample size of American Bullfrogs and Little Grass Frogs, it is premature to determine rates of infection. Although a histological examination was not performed, it appeared that *Bd* was the cause of death for the Little Grass Frog, as symptoms matched those described in a previous report for another species (Todd-Thompson 2009).

Optimal pathogen growth in culture has been reported to occur at 23ºC (Daszak et al. 2003). Further laboratory experiments have indicated that *Bd* does not grow or grows slowly at temperatures above 28°C, suggesting infections at these temperatures may not be fatal (Piotrowski et al. 2004). To increase the probability of detection in the previous study (Rizkalla 2009), sample collection was restricted to the cooler months of the year. In this study, sampling occurred year round to increase the sample size. There were four cases of *Bd* when high air temperatures were above 28ºC, including the Little Grass Frog sampled in April when the air temperature was 31°C and an American Bullfrog sampled in July at 38°C.

It is possible that water temperatures and shaded areas may not have been as warm as the ambient temperature recorded at the weather station. Thus, it could be difficult to attribute the fatality of the Little Grass Frog to *Bd* despite the high temperature. However, species' behavior should also be a consideration. Little Grass Frogs tend to perch in vegetation above the water line (Conant and Collins 1998). Similarly, other *Bd*-positive species in this study, such as Florida Cricket Frog and Southern Toad, exhibit diurnal or terrestrial activity which would expose them to warm temperatures for prolonged periods (which is a recommended treatment for captive species (Piotrowski et al. 2004)). Thus, infection in these species is notable.

The unique patterns of infection observed in central Florida may be an artifact of a particular strain of the fungus. The pathogen is also capable of adapting to changing temperatures (Woodhams et al. 2008), trading fecundity for maturation rate; as temperatures increased, growth rate increased but fewer zoospores were produced per zoosporangium. However, temperatures above 28°C were not tested, and laboratory conditions may not accurately represent the behavior of the pathogen in the wild. Thus, warm temperatures could explain the low prevalence observed in central Florida but it could take a low zoospore load to cause fatality. We should not presume that species in warm climates are less likely to be impacted by *Bd* infection. Sampling should occur throughout the year to improve estimates of prevalence.

Acknowledgments.—Members of Disney's Animal Programs, including V. Alford, A. Daneault, T. Probst, and J. Sincage assisted in sample collection. A. Savage provided useful comments on earlier versions of this manuscript. This study is in accordance with applicable institutional Animal Care guidelines and required state research permits were obtained. I gratefully acknowledge Disney's Animal Programs Cast Conservation Program for funding.

The Rocky Mountain Tailed Frog, *Ascaphus montanus*, is a small, semi-aquatic frog found in cold, torrential streams of the northwestern United States. Tailed frogs are the most basal living anurans and possess a number of unusual features as adults including a tail-like intromittent organ, vestigial tail-wagging muscle, nine presacral vertebrae, and free ribs (Duellman and Trueb 1994). In addition, *Ascaphus* tadpoles possess a suctorial mouth which they use to climb rocks amid strong currents in order to feed on periphyton (Altig and Brodie 1972). Tailed frogs are not available commercially and knowledge of laboratory husbandry is limited (Held 1985). Given the increased risk of chytridiomycosis in stream-dwelling frogs (Kriger and Hero 2007), the presence of chytrid fungus in the northwestern United States (Muths et al. 2008; Pearl et al. 2007), and documented infection in another stream-dwelling leiopelmatid frog (*Leiopelma archeyi*; Bell et al. 2004), the development of husbandry techniques for this unique frog is increasingly important. As a torrent species, tailed frogs present a particular challenge because of their unusual habitat requirements.

Our objective was to mimic as closely as possible the first-order streams typically inhabited by adult tailed frogs. Key features of those streams include high flow rates, cold temperatures, slightly acidic pH, and granite cobbles. Herein we present husbandry in-

formation gathered over 2 ½ years (July 2007–December 2009) for a colony of adults (N = 16; 8 male, 8 female) and tadpoles (N = 15; 1–3 years of age; see Metter 1967 for aging criteria).

Individuals were collected by hand from streams in the Payette National Forest, Valley County, Idaho, USA and placed in individual plastic containers (Gladware) filled with stream water. Holes were placed in lids for aeration and containers were stacked and kept cool with a 12-V thermoelectric cooler (Igloo PowerChill). Animals were transported by automobile to the animal care facility at Southern Illinois University Edwardsville. Upon arrival, animals were acclimated by gradual addition of aquarium water to individual containers.

Adults (N = 16) and tadpoles (N = 15) were placed separately in two rectangular aquaria constructed from 1.9 cm × 28.6 cm pine boards (Fig. 1). Inside dimensions were 121.9 cm × 27.9 cm × 26.7 cm. Angle brackets were used to join boards together at corners. The interior surface of the floors and walls of the aquaria were coated with waterproof blue marine paint and sealed with silicone aquarium sealant. Lids were constructed from 0.16 cm thick Plexiglass with 0.5 cm diameter holes spaced approximately 10.0 cm apart for aeration. The floor of each aquarium included a filter-guarded drainage hole at one end. Aquaria were placed adjacent to one another on wooden scaffolding located above a 1.5 m diameter round plastic tub that served as a reservoir tank. The complete setup contained approximately 265 L of deionized water.

Water flow was powered by a 9085 Lph submersible utility pump (Supreme model 24) placed at the bottom of the reservoir. Water was filtered at the intake with a filter canister and sleeve (Marineland Magnum) containing a mixture of activated carbon and ammonia removing media (Aquarium Pharmaceuticals Ammocarb). A 10 cm length of plastic tubing connected the filter canister to 1.9 cm inside diameter schedule 40 PVC pipe. Filtered water was pumped to a ½ hp chiller (Aqua Logic Delta Star) cycled at 20-minute intervals with a plug-in timer to maintain a temperature of 9 ± 1°C, near the temperature recommended by Pough (2007) for cold water amphibians such as *Ascaphus*. Chilled water was directed over each aquarium with additional 1.9 cm PVC with flow controlled via stopcocks. Water flowed into aquaria from above through a 5.0 cm opening in the Plexiglas lid, simulating a cascading stream and providing aeration. A third stopcock directed excess water into the plastic reservoir tank. Water depth was maintained in aquaria at 7 cm with a PVC standpipe attached to the coarse filter. The pH was kept at ~6.8 by placing a nylon mesh bag of sphagnum peat moss in the reservoir tank. Lighting cycles were adjusted monthly to reflect seasonal changes in photoperiod. In addition, a 26 W fluorescent light bulb was used to provide low-level lighting at night for prey detection during feeding (Pough 2007). Room temperature was kept at 20°C.

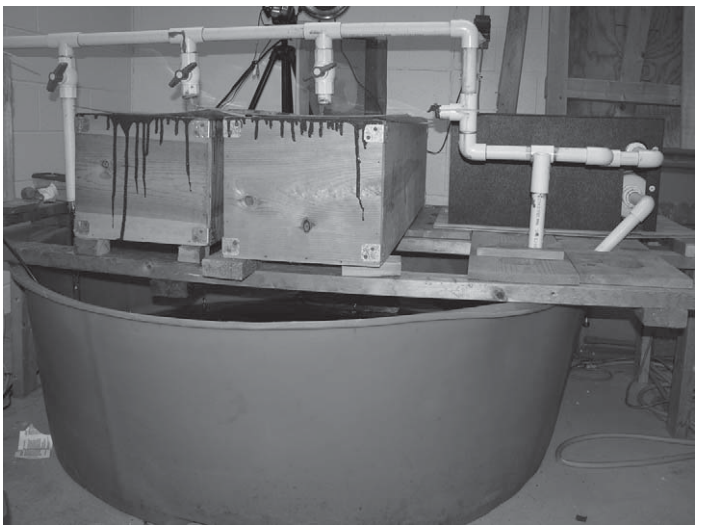

FIG. 1. Husbandry setup for a colony of Rocky Mountain Tailed Frogs, *Ascaphus montanus*. Adult frogs (N = 16) and tadpoles (N = 15) are housed separately in rectangular aquaria containing aquarium gravel and granite cobbles. Deionized water is chilled and circulated into the aquaria and reservoir tank via PVC.

Aquarium substrates consisted of aquarium gravel and granite cobbles of varying diameters (range = 5–30 cm) purchased from a landscape supplier. Cobbles were placed in an overlapping arrangement to provide refugia for adults. Large flat cobbles protruding from the water were used as feeding platforms for adults. Cobbles also served as a feeding surface for tadpoles which moved along them using their suctorial mouths (Altig and Brodie 1972).

Water quality (pH, alkalinity, chlorine, hardness, nitrite, nitrate) was tested twice weekly with test strips (Jungle Quick Dip) or with a pH meter (Hanna HI98103). Increases in nitrite or nitrate levels were controlled with water conditioner (Kordon Amquel Plus). Slight decreases in pH were adjusted as needed with a phosphate-based buffer (Seachem Neutral Regulator). Water levels were checked frequently and any losses due to evaporation were replaced as needed. Aquaria were cleaned and water was changed completely on a bimonthly basis. The health status of adults and tadpoles was monitored weekly by lifting large rocks and visually examining and censusing all individuals. Nitrile gloves were used whenever it was necessary to handle individuals or aquarium contents in order to reduce the likelihood of pathogen transmission.

Adult tailed frogs are known to eat a variety of arthropods, including Orthopterans (Bury 1970; Held 1985; Metter 1964). We fed adults twice weekly with 1.0–1.5 cm gut-loaded crickets purchased from Timberline Fisheries, Inc. (Marion, Illinois). Crickets were maintained on a diet of Timberline Cricket Power Food. Tadpoles were fed periphyton that became established on cobbles from two sources: 1) introduction of original stream water from transport containers; and 2) addition of a colony of living diatoms and desmids from Carolina Biological (Burlington, North Carolina). Once periphyton became established, cobbles developing an algal coat in the adult aquarium were transferred to the tadpole aquarium to provide additional food.

Adult frogs were marked for individual identification by injection with white visible implant elastomer in the webbing between digits of the pes (Northwest Marine Technology, Shaw Island, Washington; Nauwelaerts et al. 2000). Prior to marking, adults were anesthetized by immersion in tricaine methanesulfonate (MS-222) at a dose of 1.0 g/L. Individuals were removed from anesthesia once they lost the righting reflex.

After 18 months individuals were weighed to monitor changes in growth. All individuals experienced growth over this period with the greatest increases in body mass occurring in females. The mean body mass (± SD) at time of capture for 12 surviving adults (from a starting population of N = 16) was 4.37 ± 0.24 g for males (N = 6) and 6.73 ± 0.86 g for females (N = 6; Table 1). The percent increase in body mass over 18 months in captivity was 22.2

± 9.4% for males and 67.4 ± 36.7% for females (Table 1). Initially, 4 out of 8 females were visibly gravid at the time of capture. After 18 months 6 out of 6 remaining females were gravid. During this time period follicles (visible through the skin) became noticeably larger. Presumably, the greater increase in female body mass was due largely to gravidity.

TABLE 1. Change in body mass for a colony of Rocky Mountain tailed frogs, *Ascaphus montanus*, during the first 18 months in captivity.

Males			Females		
Mass 07/01/07	Mass 01/01/09	% Increase	Mass 07/01/07	Mass 01/01/09	% Increase
4.59	5.2	13.3	8.28	9.34	12.8
4.07	4.67	14.7	7.0	10.68	52.6

* indicates mortality

Male nuptial pads began to appear in October 2007 and persisted throughout the observation period. Copulexus *sensu* Sever et al. (2001) was observed on 12 occasions, with the earliest observation occurring on 19 May and the latest on 3 January (Fig. 2). Durations ranged from 1–3 days and no males were observed displacing rivals. Extended copulexus and an absence of male-male combat was previously reported by Stephenson and Verrell (2003) in a laboratory study of reproductive behavior in *Ascaphus.* Of the 12 events observed in our colony, only two involved pairings of the same individuals. Stephenson and Verrell (2003) also determined that there was no significant relationship between body mass and mating success in male *Ascaphus.* Our observations are consistent with this, since males in our colony exhibited similar numbers of copulations regardless of size. Courtship behavior involving males grasping unreceptive females in the absence of copulation occurred throughout the year as described by Metter (1967).

To date, we have not observed oviposition in the laboratory, despite providing conditions similar to those characterizing oviposition sites in *Ascaphus montanus* (see Karraker et al. 2006). Held (1985) had a similar experience with the Coastal Tailed Frog, *A. truei*. Karraker et al. (2006) determined that water temperature explained the greatest amount of variation in the timing of oviposition in *A. montanus*. Our setup maintained a relatively constant water temperature of 9 ± 1°C, within the range 11.4 ± 2.9°C reported by Karraker et al. (2006) for oviposition sites. Gradually increasing water temperature and photoperiod might be a way to stimulate natural oviposition. Alternatively, oviposition could be induced through injection of hormones (Brown 1975; Noble and Putnam 1931).

Four (3-year old) tadpoles metamorphosed from November to December 2007. The temperature range at which metamorphosis occurred (9 ± 1°C) was near the optimum reported for inducing metamorphosis in *Ascaphus truei* (10°C; Brown 1990). The first two individuals to metamorphose were placed in the adult aquarium. These individuals disappeared after several days and were assumed to have been cannibalized. We subsequently added a separate 18.9 L glass aquarium with a similar drainage system and substrate for juveniles. A T-fitting was inserted into the PVC pipe to divert water to a fourth stopcock above the aquarium. The two remaining froglets were fed a diet of flightless *Drosophila melanogaster* from Timberline Fisheries, Inc. (Marion, Illinois) *ad libitum* for approximately 1 month, at which point both stopped eating and died. In retrospect, a diet of flightless *Drosophila* raised on standard fruit fly media was probably insufficient for raising newly metamorphosed froglets. This stage of rapid growth and development might require the addition of supplemental nutrients (e.g. calcium) to *Drosophila* media.

After approximately 8 months in captivity (March 2008), three adult specimens (two males and one female) developed skin lesions and became noticeably lethargic. It was assumed that they had contracted an infection from an unknown pathogen, possibly due to the introduction of food (crickets) or from cross-contamination from a nearby colony of leopard frogs (*Rana pipiens*) maintained in the animal care facility. In response, water was changed completely and a broad spectrum treatment with antibiotics (Mardel Maracyn [tetracycline]), fungicides (Jungle Fungus Clear), and anti-protozoan medication (Aquarium Products Quick Cure) at dosages recommended for sensitive fish, was initiated for a one-week

FIG. 2. Copulexus in a pair of captive Rocky Mountain Tailed Frogs, *Ascaphus montanus*.

COLOR REPRODUCTION SUPPORTED BY THE THOMAS BEAUVAIS FUND

period. Water temperature was raised to room temperature (20°C) and carbon was removed from the filter to prevent adsorption of medications. All three individuals died, but no further adult mortality occurred at that time. A necropsy was performed on one of the specimens by a veterinary pathologist. Histological sections were prepared by staining with H&E and silver. Upon examination, no evidence of disease or fungal infection was observed and a cause of death could not be determined.

Unfortunately, the antibiotic treatment altered the microbial flora in the tank resulting in a precipitous drop in pH (<5) approximately three weeks after completion of the broad spectrum treatment. This resulted in 100% tadpole mortality. There were no noticeable effects on adults, presumably due to their ability to climb onto rocks. Following the loss of tadpoles, adults were redistributed to take advantage of the additional space (Tank 1: N = 7; Tank 2: N = 6).

A fourth adult frog (gravid female) became lethargic in August 2008 and died. A cluster of ~40 eggs was removed postmortem and placed under a granite cobble directly beneath the inflow pipe to encourage development. However, the eggs soon became enveloped in a coat of filamentous fungus and failed to develop. A necropsy was also performed on this individual using the same methods described earlier, but a cause of death could not be determined.

In conclusion, this husbandry setup represents a good starting point for keeping *Ascaphus montanus* in captivity. The frequency with which they engage in copulexus in the laboratory makes captive breeding a possibility; however, oviposition remains a challenge. The described setup is relatively inexpensive, easily reproducible, and will provide a suitable environment for tailed frogs over an extended period of time.

Acknowledgments.—We thank Gina Bonaminio, Dick Brugam, Paul Brunkow, Bruce Bury, John Cossel, Dave Duvernell, Ana Egnew, Marc Hayes, Brent Matsuda, Brad Moon, Marilyn Nielson, Jake Schaeffer, and Chris Theodorakis for advice with specimen collection and/or husbandry. We thank John Sagartz of Seventh Wave Laboratories for conducting the necropsies. We thank the Idaho Department of Fish and Game and the United States Forest Service/Payette National Forest for granting collecting permits. This study was funded by a Funded University Research grant and a Summer Research Fellowship from Southern Illinois University Edwardsville. All animals were maintained in accordance with Southern Illinois University Edwardsville Institutional Animal Care and Use Committee (IACUC) guidelines.

NATURAL HISTORY NOTES

The Natural History Notes section is analogous to Geographic Distribution. Preferred notes should 1) focus on observations in the field, with little human intrusion; 2) represent more than the isolated documentation of developmental aberrations; and 3) possess a natural history perspective. Individual notes should, with few exceptions, concern only one species, and authors are requested to choose a keyword or short phrase which best describes the nature of their note (e.g., Reproduction, Morphology, Habitat, etc.). Use of figures to illustrate any data is encouraged, but should replace words rather than embellish them. The section's intent is to convey information rather than demonstrate prose. Articles submitted to this section will be reviewed and edited prior to acceptance.

Electronic submission of manuscripts is requested (as Microsoft Word or Rich Text format [rtf] files, as e-mail attachments). Figures can be submitted electronically as JPG files, although higher resolution TIFF or PDF files will be requested for publication. Please DO NOT send graphic files as imbedded figures within a text file. Additional information concerning preparation and submission of graphics files is available on the SSAR web site at: http://www.ssarherps.org/HRinfo.html. Manuscripts should be sent to the appropriate section editor: **Jackson D. Shedd** (crocodilians, lizards, and *Sphenodon*; jackson.shedd@gmail.com); **Charles W. Painter** (amphibians; charles.painter@state.nm.us); **John D. Willson** (snakes; willson@uga.edu); and **James Harding** (turtles; hardingj@msu.edu).

Standard format for this section is as follows: SCIENTIFIC NAME, COMMON NAME (for the United States and Canada as it appears in Crother [ed.] 2008. *Scientific and Standard English Names of Amphibians and Reptiles of North America North of Mexico*. SSAR Herpetol. Circ. 37:1–84, available from SSAR Publications Secretary, ssar@herplit.com; for Mexico as it appears in Liner and Casas-Andreu 2008, *Standard Spanish, English and Scientific Names of the Amphibians and Reptiles of Mexico*. Herpetol. Circ. 38:1–162), KEYWORD. DATA on the animal. Place of deposition or intended deposition of specimen(s), and catalog number(s). Then skip a line and close with SUBMITTED BY (give name and address in full—spell out state names—no abbreviations). (NCN) should be used for common name where none is recognized. References may be briefly cited in text (refer to this issue for citation format).

Some further comments. The role of the "Standard Names" lists (noted above) is to standardize English names and comment on the current scientific names. Scientific names are hypotheses (or at least represent them) and as such their usage should not be dictated by a list, society, or journal.

Recommended citation for notes appearing in this section is: Medina, P., and R. L. Joglar. 2008. *Eleutherodactylus richmondi*: reproduction. Herpetol. Rev. 39:460.

CAUDATA — SALAMANDERS

AMBYSTOMA MACULATUM (Spotted Salamander). **UNUSUAL MALFORMATION**. Malformations such as missing and extra limbs and digits have been observed in both salamander and frog species at least since the mid-1990s (Johnson et al. 2002. Ecol. Monogr. 72:151–168; Lannoo 2005. Amphibians Declines: The Conservation Status of United States Species. Univ. California Press, Berkeley, California. xxi + 1094 pp.). On 28 March 2009, I captured a female *Ambystoma maculatum* at the Central Kentucky Wildlife Management Area, Madison County, Kentucky, USA (37.6299156°N, 84.1961575°W) that possessed an unusual growth directly adjacent to the cloaca. The growth appeared to be a fully formed toe having the same banding pattern, length, and keratinized tip as the individual's normally placed toes. No other abnormalities were present on this individual. However, this and other malformations involving digits and appendages have been observed in other individuals of this species at this location.

Submitted by **MICHELLE GUIDUGLI**, Department of Biological Sciences, Eastern Kentucky University, Richmond, Kentucky 40475, USA; e-mail: michelle_guidugli@eku.edu.

FIG. 1. Photograph showing an *Ambystoma maculatum* female with a fully formed toe adjacent to the cloaca. Note that all limbs were present and showed no sign of malformation.

AMBYSTOMA OPACUM (Marbled Salamander). **COLORATION**. Color anomalies have been well documented in amphibians, especially albinism (Bechtel 1995. Reptile and Amphibian Variants: Colors, Patterns, and Scales. Krieger Publ., Malabar, Florida. 224 pp.; Hensley 1959. Publ. Michigan State Univ. [Biol.] 1:133–159). Accounts of partial albino Marbled Salamanders are known from Maryland, Mississippi, and Illinois (Dyrkacz 1981. Herpetol. Cir. 11:1–31; Walston 2004. Herpetol. Rev. 35:365). Further, Mitchell (2002. Banisteria 24:67–69) has reported capture of leucistic *A. opacum* larvae in Virginia. However, accounts of darker variants are lacking in comparison to reports of albinism (Richards and Nace 1983. Copeia 1983:979–990). In the family Ambystomatidae, observations of melanistic Spotted Salamanders (*A. maculatum*) are known from Arkansas (Easterla 1972. Herpetologica 24:330–331) and a melanistic Axolotl (*A. mexicanum*) was reported by Humphrey and Bagnara (1979. J. Hered. 58:251–256). Here, we have adapted the term "melanoid," first used by Humphrey and Bagnara (1979, *op. cit.*) and later by Richards and Nace (1983, *op. cit.*), to describe all of our melanistic specimens due to the varying degrees of melanism in each. Thus, we report the first known captures of three melanoid and one hypomelanistic *A. opacum* in Tennessee. A melanoid adult male (63 mm SVL, 7 g) was observed at the Volunteer Army Ammunition Plant (VAAP) site in Hamilton Co., Tennessee (35.10437°N, 85.13053°W) on 9 Oct 2007. The specimen exhibited an overall black coloration, completely lacking the conspicuous white patterns usually present in male *A. opacum* (Petranka 1998. Salamanders of the United States and Canada. Smithsonian Institution Press, Washington, D.C. 587 pp.). At the same location, a melanoid female (66 mm SVL, 10 g) was observed on 8 Oct 2008. This specimen exhibited regular patterning on the dorsal surface, although all patterned areas were extremely faint and almost completely hidden. Our third melanoid specimen was a female (72 mm SVL, 7 g) observed at the VAAP site on 11 Dec 2008. Again, remnants of white crossbands were almost entirely undetectable. Lastly, a hypomelanistic

adult female (67 mm SVL, 8 g) was observed at the VAAP site on 8 Oct 2008 during autumn breeding movements. The specimen exhibited an overall pinkish-purple coloration due to the decrease in melanophores, with the white crossbands appearing normal. All specimens were collected under TWRA Permit No. 3082 and UTC AUP No. 0408TPW-04.

Submitted by **JOSEPH F. SIMPSON** (e-mail: joseph-simpson@utc.edu), and **THOMAS P. WILSON** (e-mail: thomas-wilson@utc.edu), Department of Biological and Environmental Sciences, University of Tennessee at Chattanooga, 615 McCallie Avenue, Chattanooga, Tennessee 37403, USA.

AMBYSTOMA TIGRINUM (Tiger Salamander). **PREDATION**. Birds have been hypothesized to prey upon Tiger Salamander larvae when they are trapped in drying ponds (Petranka 1998. Salamanders of the United States and Canada. Smithsonian Institution Press, Washington D.C. 587 pp.; Lannoo and Phillips 2005. *In* M. J. Lannoo [ed.], Amphibian Declines: The Conservation Status of United States Species, pp. 636–639. Univ. California Press, Berkeley). However, aquatic predation by birds on Tiger Salamander larvae has not been confirmed. On 4 Aug 2008, at 1230 h, we observed an adult *Ardea herodias* (Great Blue Heron) capture and eat a large larval *Ambystoma tigrinum* at Jasper-Pulaski Fish and Wildlife Area, in Jasper County, Indiana, USA (41.1576111°N, 86.9703333°W). The heron was observed wading in a wetland and struck at prey under the surface of the water. It held a salamander larva in its bill for a few minutes before swallowing it whole. During this time we were able to identify the salamander larva by observation through a 10-power spotting scope. Its size and the presence of four limbs ruled out all other species known at the site.

AMBYSTOMA TIGRINUM TIGRINUM (Eastern Tiger Salamander). **REPRODUCTION**. Terrestrial salamanders of the family Ambystomatidae typically reproduce through explosive breeding aggregations formed in temporary and permanent water bodies. Among species known to utilize this strategy, breeding is typically associated with precipitation events and occurs at night (Petranka 1998. Salamanders of the United States and Canada. Smithsonian Institution Press, Washington. 587 pp.). Here, however, I report repeated observations of diurnal breeding activities within populations of *A. t. tigrinum* in southern Illinois.

Between 9 Feb and 15 March 2008, nine individual *A. t. tigrinum* (five females, four males) were observed engaged in diurnal breeding activities within two forested ponds of the Shawnee National Forest, Gallatin and Hardin counties, Illinois, USA (37.60569°N, 88.25950°W and 37.57192 °N, 88.25472°W). Breeding behaviors were observed between 1210–1520 h and consisted of males and females depositing spermatophores and egg masses on submerged tree branches and vegetation. Ponds were characterized by high turbidity at all times during these observations, with Secchi disk transparencies ranging from 0.18–0.41 cm (N = 10 readings/pond). No ice was observed on the ponds' surfaces, and skies were clear.

To my knowledge, this is the first report of diurnal breeding activities by any pond-breeding ambystomatid salamander. These preliminary observations suggest that light cues necessary for the formation of nocturnal breeding aggregations among ambystomatid salamanders are absent or reduced in ponds with high turbidity, resulting in diurnal breeding because individuals are unable to recognize an external photoperiod. In adjacent ponds with clear water (i.e., Secchi disk transparencies exceeding the actual pond depth), breeding activities were only observed at night, though on the same dates as the diurnal activities described above. Many of the permanent fishless ponds within the Shawnee Forest exhibit similarly high turbidity, attributable to substrates composed of well-decomposed organic muck and constant resuspension of particles by precipitation events. Therefore, in these ponds, diurnal breeding activities may be commonplace, and future studies should focus on ponds with high turbidity to determine the prevalence of these behaviors.

All research was conducted in accordance with Southern Illinois University Carbondale IACUC Protocol # 05-036 and with permission of the United States Forest Service. This research was funded by a grant from the Chicago Herpetological Society.

BOLITOGLOSSA ORESTES (Culata Climbing Salamander) and ***BOLITOGLOSSA SPONGAI*** (NCN). **LIFE HSTORY**. Herein we report information on reproduction, habitat, and diet of two plethodontid salamanders from the cloud forests of Mérida, Venezuela. A removal survey was conducted during June to August 2008, in La Mucuy, San Javier del Valle, and San Eusebio cloud forests. For all specimens, length (SVL, from tip of snout to the anterior edge of vent) was measured. Specimens were dissected to determine sex and reproductive condition; egg number and diameter were measured; testis length and width were measured and surface average was calculated. The stomach contents were washed from the dissected stomach, separated, and identified with a dissecting microscope. All specimens were deposited in the Amphibians and Reptiles Collection of the Universidad de Los Andes (CVULA).

Salamanders were found within logs and moist litter associated with mats of mosses and lichens. The majority of prey items were soil invertebrates including ants, pseudoscorpions, spiders, acari, beetles, and isopods.

Two gravid female *Bolitoglossa orestes* (CVULA 7101, 7108) collected in San Javier del Valle, had enlarged and convoluted oviducts with two rows of 8 light yellow, yolk-filled eggs. Eggs were joined together without pedicels. Female size and average diameter egg are given in Table 1. A small female (CVULA 7099) collected in La Mucuy, had a total of 56 whitish jelly eggs of different sizes and its oviducts were straight. One male (CVULA 7109) collected in San Javier del Valle has small white testes.

An adult female *Bolitoglossa spongai* from San Eusebio Forest (CVULA 7092) with an enlarged and convoluted oviduct had only

TABLE 1. Reproductive characteristics of *Bolitoglossa orestes* and *Bolitoglossa spongai* collected in three cloud forests of the Andes of Venezuela.

Species	CVULA	Date	SVL (mm)	Sex	Oviductal egg number right / left	Mean egg diameter (mm)	Mean testis surface (mm^2) right / left
B. orestes	7101	07/17/08	102.66	F	8/8	1.33 ± 0.25	—
B. orestes	7108	07/17/08	99.81	F	8/8	1.51 ± 0.21	—
B. orestes	7109	07/17/08	70.81	M	—	—	6.73/8.98
B. orestes	7099	06/27/08	74.00	F	31/25	0.42 ± 0.06	—
B. spongai	7092	06/13/08	103.00	F	11/10	1.7 ± 0.54	—
B. spongai	7096	06/13/08	94.00	M	—	—	14.23/13.56
B. spongai	7094	06/13/08	70.00	M	—	—	10.32/9.74

21 large yellow yolk-filled eggs. Two males (CVULA 7096 and 7094) were collected in the same locality with whitish enlarged testes. Despite the small sample size in each species, SVL for females exceeds that of males (Table 1).

The best predictors of salamander presence at these sites were deep ground cover and high humidity. From this field work we concluded that subterranean elements are important components of the salamander environment. Based on egg numbers and egg development they might reproduce throughout the year as other tropical species Chan (2003. J. Linn. Soc. 78[4]:489–496). Many aspects of the biology and natural history of these salamander species remain to be ascertained.

BOLITOGLOSSA STRIATULA (Striated Salamander). **PREDATION**. *Bolitoglossa striatula* is the only salamander in Costa Rica with paired dorsal and lateral dark longitudinal stripes. This species forages on the leaves of herbaceous vegetation at night and hides during the day in the plants located near ponds. Many aspects of its biology are unknown. This is the first report of predation of *B. striatula*.

On 15 April 2004 at 1100 h, an individual *Micrurus nigrocinctus* (Central American Coralsnake) (300 mm SVL) was captured near an artificial pond at the University of Costa Rica, campus "Sede de Occidente," San Ramón, Alajuela, Costa Rica (10.083°N; 84.467°W; 1070 m elev.). The snake was placed in a glass bottle where it regurgitated a *B. striatula* (55 mm SVL, 65 mm TL) 30 min later. The *B. striatula* was partly digested, and was deposited at the Museo de Zoología, Universidad de Costa Rica (UCR 17581).

In Costa Rica, the diet of *M. nigrocinctus* is primarily colubrid snakes, small lizards, and occasionally members of their own species (Solórzano 2004. Snakes of Costa Rica: Distribution, Taxonomy and Natural History. INBio. Santo Domingo, Heredia, Costa Rica. 792 pp.). This is the first record of a salamander in its diet.

I thank J. M. Mora, F. Bolaños, and C. Charpentier for comments on this manuscript.

DICAMPTODON TENEBROSUS (Coastal Giant Salamander). **REPRODUCTION**. Little is known about the nesting habits of *Dicamptodon* spp. Only three observations of *D. tenebrosus* nests have been published (Henry and Twitty 1940. Copeia 1940[4]:247–250; Nussbaum 1969. Herpetologica 25[4]:257–262; Jones et al. 1990. Northwest. Nat. 71:93–94). On 19 Sept 2007, at 1415 h, we observed a terrestrial adult (SVL 158.0 mm, 96.7 g), with eggs and recently hatched larvae. It was located in a first order tributary of Texas Creek, about 16 km NE of Washougal, Washington, USA, in the Cascades Mountains at 447 m elev. When the nest site was disturbed, a terrestrial adult *D. tenebrosus*, presumed to be the female, appeared from under a downed log directly adjacent to the boulder where the nest was located. The presence of the female tending to the nest is consistent with observations made at other nest sites (Henry and Twitty 1940, *op. cit.*; Nussbaum 1969, *op. cit.*). There was at least one embryo and ca. 6 hatchlings. The nest appeared to have originally contained 20–30 eggs, fewer than the 70 eggs observed in other documented *D. tenebrosus* nests (Henry and Twitty 1940, *op. cit.*; Nussbaum 1969, *op. cit.*). The remaining embryo was separated from the other empty egg casings, possibly due to the disturbance. The hatchlings, which still contained their yolk sacs, were in close proximity to one other and the remnants of the nest. The nest was in 5 cm of 10°C water, under a flat boulder with a substrate of fine gravel next to the stream bank. Surrounding vegetation included Salmonberry (*Rubus spectabilis*), Vine Maple (*Acer circinatum*), and Red Alder (*Alnus rubra*). The pedicels of the eggs attached to the rock were indicative of *D. tenebrosus* as compared to *D. copei* (Steele et al. 2003. Herpetol. Rev. 34:227–228). On 20 Sept, JGM returned to the site to retrieve a tail clip for genetic analysis for species confirmation and the adult was still present, but no larvae were found. However, several crayfish (*Pacifastacus* sp.) were at the nest site, suggesting predation of the larvae. Genotyping was performed in the laboratory of Andrew Storfer (School of Biological Sciences, Washington State University) and confirmed that the adult was *D. tenebrosus.*

EURYCEA JUNALUSKA (Junaluska Salamander). **OCCURRENCE AND REPRODUCTION**. *Eurycea junaluska*, a rare salamander in southwestern North Carolina and southeastern Tennessee, is thought to be extirpated from the Cheoah River in Graham County, North Carolina (Ryan and Sever 2005. *In* M.

J. Lannoo [ed.], Amphibian Declines: The Conservation Status of United States Species, pp. 745–746. Univ. California Press, Berkeley, California). Additionally, it is reported that around mid-May adults attend egg clutches in streams (Ryan and Sever 2005, *op. cit*.) Contrary to these reports, we discovered three adult *E. junaluska* attending their egg clutches on 12–13 April 2005 in the Cheoah River, Graham County, North Carolina, along with one live adult crossing a wet road from deciduous forest toward this river during a nighttime search. All three egg clutches were deposited in cup-shaped depressions on the underside of large cobble or small boulders at the top of small riffle or run areas in the river. We observed one of the clutches hatching out which would further indicate an earlier date of egg deposition than reported in published accounts. Egg counts were ca. 36 from the hatching clutch, with 31 and 58 eggs in the remaining two clutches. On 19 Sept 2005 we observed a large, gilled larva (90 mm TL, 46 mm SVL) in the Cheoah River 200 m upstream from the previous location and one adult under artificial cover in adjacent riparian habitat, and on 14 June 2006 in aquatic searches, we found one adult in this same area. Voucher photos were verified by J. C. Beane, North Carolina State Museum of Natural Sciences (accession numbers 12294 and 12352).

NOTOPHTHALAMUS VIRIDESCENS (Eastern Newt). **POLYMELIA**. The presence of extraneous limbs (polymelia) is known to naturally occur in both larval and adult salamanders (Sessions and Ruth 1990. J. Exp. Zool. 254:38–47; Cecala et al. 2007. Herpetol. Rev. 38:434). Emergent research suggests that although polymelia in wild salamander populations does occur, it is rare (Williams et al. 2008. Biol. Lett. 4:549–552) and may be associated with trematode parasites (Johnson et al. 2006. Ecology 87:2227–2235). In North America, in situ examples of polymelia are primarily restricted to ambystomatid salamanders (e.g., Johnson et al. 2003. Cons. Biol. 17:1724–1737). For the extant Nearctic salamandrid genera (*Taricha* and *Notophthalamus*), records of polymelia are few and restricted to the hind limbs (North American Reporting Center for Amphibian Malformations [NARCAM] website; via http://www.nbii.gov). Here we report a naturally occurring case of forelimb polymelia in *N. viridescens*. On 29 Sept 2007 we collected an eft stage *N. viridescens* near the city of Lindale (Smith County., Texas, USA) from underneath a fallen log along County Road 4106 (32.57°N, 95.35°W). The specimen (SVL 19.19 mm, TL 15.90 mm) possesses two right forelimbs that coalesce near the midpoint of the humerus (Fig. 1). Based on external examination it appears that the bones comprising each arm include at least a partial humerus in addition to a full radius and ulna. Other than exhibiting polydactyly (two extra digits) and associated brachydactyly, the extraneous appendage (4.28 mm) appears comparable in gross morphology to its natural counterparts (4.92 mm right arm; 4.90 mm left arm) albeit slightly shorter. Although polymelia is known to occur in *N. viridescens* (Record ID 51, NARCAM website), the frequency and geographic distribution of its occurrence are not well documented.

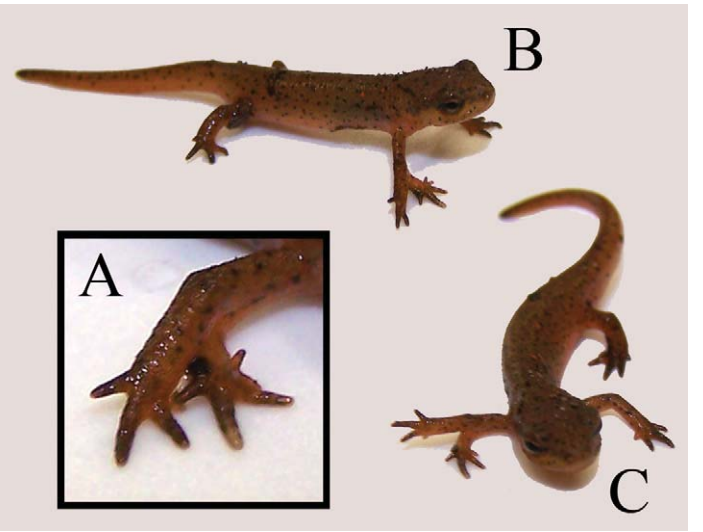

FIG. 1. Close-up (A), lateral (B), and dorso-frontal (C) views of forelimb polymelia in an eft stage *Notophthalamus viridescens* (UTA A-59131) from eastern Texas, USA.

The specimen was deposited at the University of Texas at Arlington Amphibian and Reptile Diversity Research Center (UTA A-59131) and in vivo photographic vouchers were deposited in the UTA Digital Collection (UTADC 3494–3500). All measurements were taken using a digital caliper. Limb measurements were taken distally from the elbow. We thank C. M. Sheehy III for comments on the manuscript. Collecting was conducted under Texas Parks and Wildlife scientific permit number SPR-0707-1387 to CJF.

Submitted by **JEFFREY W. STREICHER** (e-mail: streicher@uta.edu), and **CARL J. FRANKLIN**, Amphibian and Reptile Diversity Research Center, Department of Biology, University of Texas at Arlington, Arlington, Texas 76019, USA.

NOTOPHTHALMUS VIRIDESCENS (Eastern Newt). **OVERWINTERING BEHAVIOR**. The movements and homing ability of *Notophthalmus viridescens* efts have been previously documented (Healy 1975. Amer. Mid. Nat. 93[1]:131–138; Gill 1978. Evolution 32[4]:839–849). In Virginia, most adults were observed to exit ponds in autumn, presumably to overwinter in terrestrial sites surrounding their resident ponds; however, considerable variation in life history has been reported across the range of this species and regular overwintering of adults in aquatic sites has been reported for other populations (Gill 1978. Ecol. Monogr. 48:145–166). Healy (1975, *op. cit*.) reported that efts were sometimes located near the base of the same tree in successive springs and that the root system of these trees may have served as winter hibernacula. Consequently, he suggested that proximity to trees in April and early May could indicate that efts at this time (in Charlton, Massachusetts) remain close to the site of their winter emergence. Congregation of juvenile *N. viridescens* at winter hibernacula has not been previously reported. Herein I describe the occurrence of such a congregation of *N. viridescens* efts at a terrestrial site believed to have been used for overwintering.

FIG. 1. Aggregation of *Notophthalmus v. viridescens* efts at hibernacula site in Ashtabula Co., Ohio, USA.

On 2 April 2006, I observed a minimum of 19 *N. viridescens* red efts congregated beneath a slab of stone (Fig. 1). The observation was made at ca. 1645 h under partly cloudy conditions with an ambient air temperature of ca. 13.5°C. The stone was not particularly close to the base of any trees, but was located within 30 m of a small woodland pool in Ashtabula County, Ohio, USA. The pool, which currently holds water year-round, was excavated to a depth of ca. 1–2 m about 10 years prior and an adult *N. viridescens* was observed surfacing near the edge of this pool. Beneath the slab were a number of small holes leading to subterranean spaces of unknown depth. At least one eft was observed to escape down one of these holes (Fig. 1). The group of efts encompassed a wide range of sizes and appeared to represent multiple age-classes. Also found beneath the slab was a Red-backed Salamander (*Plethodon cinereus*) and a Leopard Slug (*Limax maximus*) The spaces beneath this slab coupled with the large number of efts and the rapidity with which they moved toward the holes gave the strong impression that this site was used as winter hibernacula. A thorough search of additional cover objects in the surrounding area revealed no additional efts. To the best of my knowledge this is the first report of such behavior by *N. viridescens* efts. However, the utilization of specific sites as winter hibernacula would seem to be congruent with reports of strong homing ability and spatial cognition in this species.

PLETHODON CINEREUS (Red-backed Salamander). **LEUCISM.** Leucism, a lack of skin pigmentation caused by defective chromatophores (Bartlett and Bartlett 2005. Designer Reptiles and Amphibians. Barron's Educational Series. New York), has been recorded in a number of plethodontid salamanders (Seeliger 1945. Copeia 1945:122; Miller and Braswell 2006. Herpetol. Rev. 37:198). Documented cases of leucism in *Plethodon cinereus* exist for West Virginia (Pauley 1974. Redstart 42:104), Maryland (Harris 1968. Bull. Maryland Herpetol. Soc. 4:57-60; Mitchell and Mazur 1998. Northeast. Nat. 5:367–369), and southern Ontario (Rye 1991. Can. Field Nat. 105:573–574). Here, we report two additional cases of leucism in *P. cinereus*, in Massachusetts and New York.

During August 2007, an adult *P. cinereus* of unknown sex, white in coloration with darkly colored eyes, was discovered beneath a decaying log in the Stony Brook Reservation in West Roxbury, Suffolk County, Massachusetts (WGS84, 42.2652778°N, 71.14°W, elev. 64 m) (E. O'Brien, pers. comm.). The specimen was found within 1 m of a heavily traveled footpath in a forested area comprised predominately of *Pinus strobes* and *Fagus grandifolia* with *Comptonia peregrine*s ground cover, and was left in situ. An abundance of decaying logs was present. Both "red-backed" and "lead-backed" phenotypes of *P. cinereus* are common in the area. Several successive searches of the area were carried out over the next two weeks in an effort to photograph the specimen. On 5 Sept 2007, a leucistic adult of unknown sex measuring ca. 6.5 cm TL was found together with an adult and a neonate of the "red-backed" phenotype beneath a log in the immediate area where the original leucistic specimen was discovered (Fig. 1). Since there is no photographic record from O'Brien's original sighting, it remains unclear whether this second sighting represents the original specimen or a second individual.

On 20 Sept 2008, an adult *P. cinereus* of unknown sex (ca. 7.5 cm TL) lacking skin pigmentation and patterning with dark eyes, was discovered beneath some fallen tree bark among a 2–3 cm layer of moist leaf litter in a wooded area located directly behind the reptile house and service yard of the Wildlife Conservation Society's Bronx Zoo in Bronx County, New York (WGS84; 40.8502583°N, 73.8777417°W, elev. 20 m). The overall coloration of the specimen was white, although its skin was partially transparent, allowing visibility of some visceral organs. The wooded area is situated on a slight 10–15° north-facing incline, is bordered by service yard

FIG. 1. Leucistic *Plethodon cinereus* with "red-backed" adult and juvenile from Suffolk County, Massachusetts.

buildings to the south and a paved public pathway to the north, and is dominated by *Quercus* sp., *Acer* sp., and *Liquidambar styraciflua*. An abundance of felled trees and tree bark litter the area and provide considerable ground cover. *Plethodon cinereus* of the "red-backed" morph are common in the immediate area although no "lead-backed" or additional polymorphic phenotypes have been found.

Plethodon cinereus is considered to be one the most abundant terrestrial vertebrates in deciduous forests of northeastern North America (Burton and Likens 1975. Copeia 1975:541–546), with densities reaching up to 2.8 salamanders/m^2 (Mathis 1991. Oecologia 86:433–440). Likewise, it also has an extensive distribution, ranging from North Carolina to Quebec and westward to Minnesota (Petranka 1998. Salamanders of the United States and Canada. Smithsonian Institution Press, Washington, DC. 587 pp.). Given these attributes, combined with a general ease of locating them beneath logs, rocks, and leaf litter, it can be expected that occasional specimens exhibiting coloration abnormalities will be found. The fact that there are currently more documented cases of leucism in *P. cinereus* than any other caudate is likely an artifact of the relative abundance of *P. cinereus*, rather than a greater incidence of color anomaly in the species. Given its fossorial and nocturnal terrestrial habits (Petranka 1998, *op. cit.*), leucism as well as other conspicuous phenotypes documented for *P. cinereus* such as albinism (Hensley 1959. Pub. Mus. Michigan State. Univ., Ser. 1:135–139; Dyrkacz 1981. SSAR Herpetol. Circ. 11:1–31; Gilhen 1986. Can. Field Nat. 100:375) may not be as deleterious to *P. cinereus* as they would be for less reclusive amphibian species. Both observed leucistic individuals were adults in good physical condition and were found in close proximity to conspecifics.

Submitted by **ROBERT W. MENDYK** (e-mail: odatriad@yahoo.com), and **LAUREN AUGUSTINE** (e-mail: laugustine@wcs.org), Department of Herpetology, Wildlife Conservation Society, Bronx Zoo, 2300 Southern Blvd, Bronx, New York 10460, USA; and **GABRIEL MONTAGUE**, Children's Zoo, Zoo New England, 1 Franklin Park Rd, Boston, Massachusetts 02121, USA (e-mail: gmontague@zoonewengland.com).

PLETHODON CINEREUS (Red-backed Salamander). **ELEVATION**. On 2 Sept 2008, we observed a single dead, adult red-backed salamander in a granitic seepage at 1173 m elevation on the north headwall of the North Basin, Katahdin, Mount Katahdin Township (T3 R9 WELS), Piscataquis County, Maine, USA (45.931°N, 68.922°W). Red-backed Salamanders are commonly reported from low elevations in the Katahdin region, and have been reported at elevations exceeding 1219 m in the southern Appalachians, but similar elevation records do not exist for the northeastern United States, where tundra communities occur above 1200 m (Hunter et al. 1999. Maine Amphibians and Reptiles. University of Maine Press, Orono, Maine; Taylor 1993. The Amphibians and Reptiles of New Hampshire. Nongame and Endangered Wildlife Program, New Hampshire Fish and Game Department, Concord, New Hampshire). This record provides limited information about the potential elevational distribution of this species and is unusual because the surrounding vegetation is subalpine and arctic-alpine, a vegetation type not present in the southern Appalachians. Dominant vascular plants observed in the surrounding snowbed community included the following unusual subalpine assemblage: *Carex intumescens*, *Carex flava*, *Carex scirpoidea*, *Glyceria striata*, *Campanula rotundifolia*, *Dasiflora fruticosa*, *Sibbaldiopsis tridentata*, *Drosera rotundifolia*, *Arnica lanceolata*, and *Prenanthes trifoliolata*. *Plethodon cinereus* is not the only amphibian occurring at this elevation on Katahdin; 179 m SW of this location at a similar elevation, we observed an adult American Toad (*Anaxyrus americanus*). The amphibian communities of these northern, alpine communities are more diverse than typically acknowledged and are in need of additional, focused research.

Submitted by **LISABETH L. WILLEY** and **MICHAEL T. JONES**, Department of Natural Resources Conservation, University of Massachusetts, Amherst, Massachusetts 01003, USA.

PLETHODON DORSALIS / EURYCEA LUCIFUGA / ANEIDES AENEUS (Zigzag Salamander, Cave Salamander, Green Salamander). **ARBOREALITY**. Salamanders of the genus *Aneides* are found in arboreal habitats in temperate rainforests of northwestern North America (Spickler et al. 2006. Herpetol. Cons. Biol. 1:16–26) and hardwood forests of the eastern United States (Wilson 2003. Contemp. Herpetol. 2003[2]:1–6). However, no studies have reported the use of arboreal habitats by salamanders in the genera *Plethodon* and *Eurycea*. Herein, I report arboreal habitat use in both *Plethodon dorsalis* and *Eurycea lucifuga*. On 12 May 2005 and 15 Oct 2006, I observed *P. dorsalis* (N = 3), *E. lucifuga* (N = 5), and *Aneides aeneus* (N = 2) between 1.5 m and 4 m above ground on tree trunks (dbh greater than 114 cm). All areas of observation were adjacent to small streams. Observations were made in two different old-growth hardwood forest stands of southeastern Tennessee, USA (site 1, Dick's Cove, [35.2199417°N, 85.9599778°W]; site 2, Morgan's Steep, [35.2026833°N, 85.9320167°W]). Both sites were mesic cove forests. Individuals were observed between 2200 and 0100 h. On the two nights of observation the weather was cool with light rain. *Plethodon dorsalis* and *A. aeneus* were both observed on large Black Oak (*Quercus velutina*; site 1) while *E. lucifuga* were observed on Tulip Poplars (*Liriodendron tulipifera*; site 2). One individual *P. dorsalis* was observed foraging (ca. 2 m above ground) on small flies. These observations provide new habitat associations for both *P. dorsalis* and *E. lucifuga*.

I thank J. Berton, C. Harris, and M. Hess for assistance.

PLETHODON GLUTINOSUS (Northern Slimy Salamander). **REPRODUCTION AND BEHAVIOR.** *Plethodon glutinosus* has an extensive geographic distribution in the eastern United States. Extensively studied accounts of female reproductive behavior in nature remain sparse, leaving gaps in the knowledge of the reproductive behavior of this species. Currently much of what is known about nesting and associated behavior has been gained from observations made during experimental manipulations of brooding female *P. glutinosus*, their clutches, or nesting environments (Peterson 2000. Ethology 106:781–794; Trauth et al. 2006.

Herpetol. Nat. Hist. 9:141–149). To date, reported egg deposition sites for *P. glutinosus* include rotting stumps, logs, and under rocks (Beamer and Lannoo 2005. *In* M. J. Lannoo [ed.], Amphibian Declines: The Conservation Status of United States Species, pp. 808–811. Univ. California Press, Berkeley, California). Here we report a new type of egg deposition site used by *P. glutinosus* in the Appalachian Plateau region of northern Alabama.

On 29 Sept 2008 a female *P. glutinosus* was observed in attendance of a clutch of at least 5 observable eggs attached at a single point to the roof of a crevice, 10.37 mm height, in a sandstone/siltstone bluff along Clear Creek in Winston County, Alabama (WGS84, 34.02759°N, 87.37294°W). The observed eggs were in a late stage of development. The female was positioned partially coiled around and underneath the nest. The female remained motionless while viewing and photographing the nest. A second female *P. glutinosus* was encountered in attendance of a nest in a separate crevice within the same bluff system ca. 30 m from the first nest and female. The second female did exhibit an aggressive response while viewing the nest by moving between the clutch and the crevice opening and exhibiting an all-trunk raised (ATR) posture. This posture is considered an aggressive response in terrestrial salamanders (Jaeger 1984. Copeia 1984:309–314). The placement of the second nest within the crevice prevented a clear photograph and egg count from being taken.

HRC returned 3 Oct 2008 and found the first female still in attendance with five observable hatchlings; no eggs could be observed. The female was positioned coiled around the hatchlings. At the second nest the female was again found in attendance with the nest; no hatchlings were observed. On 23 Oct 2008 we found the female *P. glutinosus* was still in attendance at the first nest with two remaining hatchlings. The second female *P. glutinosus* was also observed in attendance of the second nest although no eggs or hatchlings were observed. Because of the depth of the second crevice it is possible that hatchlings were present but not observed from the crevice opening. We returned on 10 Nov 2008 and found no females or hatchlings in either crevices. To our knowledge this is the first record of this type of habitat use for egg deposition in *P. glutinosus*.

Digital photographs of the female and clutch and female and hatchlings were deposited in Alabama Herp Atlas Project-Digital at Auburn University; AHAP-D 206 and AHAP-D 207.

PSEUDOEURYCEA NIGROMACULATA (Black-spotted Salamander). **PREDATION**. On 27 Sept 1995 in central Veracruz, México, 6 km. S of Acultzingo (WGS84, 18. 6966°N, 97.3155°W, 2183 m. elev.), Walter Schmidt observed an adult male *Rhadinaea fulvivitis* (258 mm SVL, 119 mm TL), predating a *Pseudoeurycea nigromaculata* (56.5 mm SVL) on the forest floor. These specimens were collected and deposited at the Collection of Museo de Zoologia, Facultad de Ciencias, UNAM (*R. fulvivitis* MZFC 17669; *P. nigromaculata* MZFC 8457). This observation represents the first report of predation on this species (Parra-Olea 1998. Cat. Amer. Amphib. Rept. 664:1–2).

Submitted by **ANDRÉS ALBERTO MENDOZA-HERNÁNDEZ** and **URI OMAR GARCÍA-VÁZQUEZ** (e-mail: urigarcia@gmail.com), Laboratorio de Herpetología, Museo de Zoología, Facultad de Ciencias, UNAM, A.P. 70-399, México D.F. 04510.

PSEUDOTRITON RUBER (Red Salamander). **HABITAT USAGE / MOVEMENT**. *Pseudotriton ruber* is found in both aquatic and terrestrial habitats and can occur in relatively dry habitats away from aquatic sites (Mount 1975. The Reptiles and Amphibians of Alabama. Auburn Printing, Auburn, Alabama. 345 pp.). *Pseudotriton ruber* seldom disperses >30 m from overwintering sites (Axtell and Axtell 1948. Copeia 1948:64), however few studies document *P. ruber* migration or dispersal capabilities. In a recent survey of ephemeral ponds (N = 26) on the Cumberland Plateau, Corser (2008. Am. Midl. Nat.159:498–503) identified 18 of a potential 21 known amphibian species to breed in the region, but he did not document *P. ruber*. On 13 and 17 Oct 2006, I found three adult *P. ruber* at two different ephemeral ponds on the Cumberland Plateau (elev. 585 m) in southeastern Tennessee, USA (wetland site 1 [35.2235361°N, 85.9710694°W]; wetland site 2 [35.2361861°N, 85.8928694°W]). The Cumberland Plateau is bounded by moist cove forest, and ephemeral ponds represent the only natural body of water on the plateau. All three individuals were found under moist decaying logs within completely dry ephemeral ponds. The hydroperiod of plateau ephemeral ponds follows an annual cycle in which ponds are typically flooded between November and June and are completely dry for the remainder of the year. Two salamanders were located at a pond (site 1) greater than 388 m from the nearest possible stream habitat and the third salamander was located at a pond (site 2) over 1 km from the nearest stream. The two ephemeral ponds were 7.2 km apart. It is unlikely that *P. ruber* uses ephemeral ponds for breeding, given that the larval period is usually 1.5–3.5 years (Petranka 1998. Salamanders of the United States and Canada, Smithsonian Institute Press, Washington. 302 pp.) and that ephemeral ponds dry each year. It is also unlikely that these individuals use ephemeral ponds as overwintering sites because previous study shows that many individuals, particularly females, move back to stream habitats to overwinter (R. Bruce pers. comm.). Therefore, it is most likely that *P. ruber* has extensive dispersal capabilities that range from 388 m to over 1 km from stream sites and may use ephemeral ponds as an important moist stop over site during migration and dispersal events in an otherwise xeric, drought prone landscape. The present observations confirm that *P. ruber* uses ephemeral ponds on the Cumberland Plateau. My observations suggest that ephemeral ponds may be important to *P. ruber* on the Cumberland Plateau and further highlight the importance of ephemeral ponds in an area where wetlands are declining and federal regulatory oversight is limited (Scheffers et al. 2006. J. Field. Ornthol. 77:178–183).

I thank R. Bruce and J. B. C. Harris for comments on this note.

ACRIS CREPITANS (Northern Cricket Frog) and ***ACRIS GRYLLUS*** (Southern Cricket Frog). **INTERSPECIFIC AGONISM.** *Acris crepitans* and *A. gryllus* have sympatric ranges in the southeastern United States (Nevo and Capranica 1985. Evol. Biol. 19:147–214). In North Carolina, range overlap occurs in the Coastal Plain and Fall Zone and the species are syntopic (co-occur locally) in a few locations, but they are not known to interbreed, probably because females can recognize conspecific males by vocalizations (Micancin 2008. Ph.D dissertation, Univ. North Carolina). In *A. crepitans*, aggressive interactions between males include complex acoustic signals that include information on the individual's body size and size-independent willingness to physically interact (Burmeister et al. 2002. Anim Behav. 64:715–725). Agonistic encounters among *A. crepitans* can result in the use of an alternative mating tactic by subdominant males (i.e., satellite behavior, Wagner 1989. Behav. Ecol. Sociobiol. 25:429–436). We have observed two prominent behaviors, leg extension and grappling, in observations of both species of *Acris* in North Carolina. These behaviors are exhibited by calling males in high-density choruses or when a satellite male is in close proximity to the calling male. In leg extension, the individual repeatedly extends and contracts a hind leg in an exploratory fashion. When the foot or leg contacts another male, the individual turns to face the opponent before grappling until one male hops free. Physical interactions continue until either male moves away from the immediate area.

On 8 June 2007 at 2403 h, in an area of Merchants Millpond State Park (Gates County, North Carolina, USA) with an extensive mixed chorus of *Acris* (36.4261°N, 76.6770°W; NAD83 datum), we found an *A. crepitans* male and *A. gryllus* male interacting aggressively. We video recorded the interaction with a Canon Powershot A80 digital camera with light from two Petzl Duobelt halogen headlamps. We recorded for two 3-min periods. The aggressive interaction included leg extensions, grappling, and vocalizations by both males. The vocalizations allowed us to conclusively identify the males as *A. crepitans* and *A. gryllus* without capturing them (and thus interrupting their interaction).

Despite the exceptionally large populations of *A. crepitans* and *A. gryllus* at this location and our extensive work at the site in 2006 and 2007, this is the only case in which we have observed such prolonged physical agonism within or between the species, and we know of no previous reports of this behavior. Since conspecific recognition occurs by females at Merchants Millpond, interspecific agonism in males is likely a product of competition for calling space on aquatic macrophytes and woody debris, not competition for mates. Because male competition is mediated by vocalizations in *A. crepitans*, it is possible that the prolonged interaction we observed resulted from the inability of the two males to mediate their spacing acoustically. Future investigations of male competition in mixed choruses of *Acris* could include an analysis of the aggressive thresholds of both species toward intrusion by conspecific and heterospecific males.

Submitted by **JONATHAN P. MICANCIN**, Department of Biology, College of William and Mary, Williamsburg, Virginia 23185, USA (e-mail: jpmicancin@wm.edu); and **JEFF T. METTE**, North Carolina Museum of Natural Sciences, Raleigh, North Carolina 27601, USA (e-mail: jeff.mette@ncdenr.gov).

ACRIS GRYLLUS (Southern Cricket Frog). **DISPERSAL**. On 8 July 2004 around 0300 h at Cliffs of the Neuse State Park (Wayne County, North Carolina, USA), I observed a female Acris gryllus feeding on insects under the lights of a building (35.2412°N, 77.8873°W). If the female originated or bred at the nearest chorus of *A. gryllus* (35.2362°N, 77.8867°W), then she moved at least 562 m through forested habitat and up a hill to reach the location where I observed her.

Acris crepitans (Northern Cricket Frog) and *A. blanchardi* (Blanchard's Cricket Frog) have declined near northern range margins. In North Carolina, *A. gryllus* has also declined near the northern edge of its range and the Cliffs of the Neuse population is adjacent to that area (Micancin and Mette 2009. Zootaxa 2076:1–36). An important consideration in the conservation of cricket frogs is the extent of nonbreeding or upland habitat use. This observation indicates that the population of *A. gryllus* at Cliffs of The Neuse State Park can use upland habitat far from breeding wetlands during the breeding season. The well-known jumping ability of *Acris* apparently allows them to move far from wetlands in search of food.

BUFO BUFO (Common Toad). **DAVIAN BEHAVIOR.** Misdirected copulation with dead conspecific or other species is known as Davian behavior. It was described in mammals (Dickerman 1960. J. Mammal. 41:403), and birds (Lehner 1960. Wilson Bull. 100:293–294; Moeliker 2001. Deinsea—Annual of the Natural History Museum Rotterdam 8:243–247). In anurans it has been reported, although not as Davian behavior, in the Cane Toad (*Bufo marinus*) (Lewis 1989. Cane Toads: An Unnatural History. Doubleday. New York, New York. 98 pp.), and the Cuban Treefrog (*Osteopilus septentrionalis*) and Southern Toad (*Bufo terrestris*) (Meshaka 1996. Florida Sci. 59[2]:74–75). The first report of Davian behavior in the study area was described for *Bufo bufo* (Ayres 2008. Podarcis 9:11–12). Here I present new observations about this unusual behavior.

Field observations were made at clay pits in the Gandaras de Budiño e Ribeiras do Louro (GBRL) wetland, municipality of Porriño, NW Spain (42.1023°N, 8.6301167°W) on 6 Jan 2009. GBRL wetland consists of a complex of gallery forests, flooded areas, and artificial ponds created by the extraction of clay. Abandoned clay pits have been colonized by aquatic vegetation, and constitute an important breeding area for *B. bufo*, which are an important food resource for Eurasian Otters (*Lutra lutra*) during winter. I monitored clay pits by walking along the shore and banks, looking for anuran reproductive activities, or remains of toads predated by otters.

On 6 Jan 2008 I found three female *B. bufo* predated by otters in an area with shallow water (<20 cm deep), but in a deeper area (to 1 m deep) I found another predated female. When I recovered the corpse from the bottom of the pond, I noted a live male attached to the remains of the female (Fig. 1).

FIG. 1. Male *Bufo bufo* (top) in amplexus with a dead female conspecific that had been partially consumed by a Eurasian Otter.

This behavior is unusual, as it seems that it represents an ecological trap for male toads. The absence of sex recognition by *B. bufo* has been studied by Marco and Lizana (2002. Ethol. Ecol. Evol. 14:1–8) who reported the lack of a release call in the Iberian Green Frog (*Pelophylax perezi)* leads male *B. bufo* to amplex with this species, wasting time and energy, and missing opportunities to mate with gravid conspecific females. They also reported amplexus with the Fire Salamander (*Salamandra salamandra*), dead fishes, or pieces of wood.

Males detected in amplexus with dead females in winter 2008 were located in shallow areas and females lacked hind legs (Ayres and Garcia 2007. Galemys 19:45–50), so it seems that body shape does not affect male choice. But the pair in amplexus detected in 2009 were in deep water. This increased the risk of the male being predated by otters, and the depth did not allow the male to breath without leaving the dead female. Males in amplexus with dead females could pass several days attached to the body, which increases the risk of predation and results in a loss of mating opportunities.

It is unclear why male toads perceive corpses as suitable mates. It has been suggested that movement is a factor that leads males to grasp individuals or objects, even observer's toes (Ayres, pers. obs.; Meshaka 1996, *op. cit*.). Nevertheless, dead females remain motionless in the bottom of the ponds, which suggests that chemical factors may influence this unusual behavior. Further studies will be necessary to assess if this hypothesis is true.

Submitted by **CESAR AYRES**, CINAM Centro de Investigación e Información Ambiental – Lourizán Estrada PO-546 Pontevedra-Marín, km. 4 Apdo. de Correos 127- C.P. 36080 Lourizán - Pontevedra-Spain; e-mail: cesar@herpetologica.org.

BUFO HOUSTONENSIS (Houston Toad). **PREDATION**. Few predators of the federally endangered *Bufo* (=*Anaxyrus*) *houstonensis* have been recorded: snakes (*Nerodia erythrogaster*, *Thamnophis proximus*) predate on tadpoles (Freed and Neitman 1988. Texas J. Sci. 40:454-456), snakes (*Heterodon* sp., *N. erythrogaster*) on adult toads (USFWS 1984. Houston Toad Recovery Plan. U.S. Fish and Wildlife Service, Albuquerque, New Mexico), and red imported fire ants (*Solenopsis invicta*) on newly metamorphosed toadlets (Freed and Neitman. 1988, *op. cit*.). Here, we report the first record of predation of an adult *B. houstonensis* by another anuran, the American Bullfrog, *Rana catesbeiana*.

On 28 Mar 2008 at 2312 h, an adult female *R. catesbeiana* (158.8 mm SVL) was observed on the shoreline of a pond on the Boy Scouts of America's Griffith League Ranch in Bastrop County, Texas, where *B. houstonensis* had been and were actively breeding. American Bullfrogs are reported to eat anything they can swallow, from insects to mammals (Bolek and Janovy 2007. Herpetol. Rev. 38:325-326; Dixon 2000. Amphibians and Reptiles of Texas. 2nd ed. Texas A&M Univ. Press, College Station, Texas. 421 pp.; Frost 1935. Copeia 1935:15–18), and hence, they are potential predators of all life stages of this endangered toad. The *R. catesbeiana* was collected and later dissected to determine if predation on *B. houstonensis* had occurred. An adult male *B. houstonensis* (50.3 mm SVL) was discovered in the stomach, along with an *Acris crepitans* and three *Hyla versicolor*. We have determined this was predation rather than scavenging due to the well-preserved nature of the *B. houstonensis*. While this toad was partially digested, its cranial crests and parotids remain apparent, and spotting may be seen on its venter. Additionally, we compared its D-loop mitochondrial sequence to other sequences we generated from sympatric *Bufo* species, which support its identification as *B. houstonensis*. This record represents the first published account of *B. houstonensis* as a diet component of another anuran.

Specimens were deposited at the Texas Cooperative Wildlife Collection, Texas A&M University, College Station, Texas, USA (TCWC 93562 includes *R. catesbeiana* and its stomach contents: *B. houstonensis*, *A. crepitans*, 3 *H. versicolor*). Identification were verified by T. Hibbitts. We thank D. J. Brown and L. M. Villalobos for field and lab assistance.

Submitted by **DIANA J. McHENRY**, Division of Biological Sciences, University of Missouri, Columbia, Missouri 65211, USA; **MICHELE A. GASTON** and **MICHAEL R. J. FORSTNER**, Department of Biology, Texas State University, San Marcos, Texas 78666, USA (e-mail: mf@txstate.edu).

BUFO PARITALIS (Forest Toad). **DIURNAL RETREAT**. *Bufo paritalis* is a large, rare, and little-known, endemic toad that lives in the tropical rainforests of the Western Ghats (Molur and Sally 1998. Zoo's Print 13[12]:29). Little information on the distribution and natural history of the species exists (Daniels 1992. Hamadryad 17:40-42; Krishna and Krishna 2004. Herpetol. Rev. 35:156-157; Krishna and Krishna 2001. J. Bombay Nat. Hist. Soc. 98:456-457). From 18 Feb to 17 March 1999, I studied the breeding behavior and reproduction of *B. paritalis* at the Bisle Reserve Forests of the Western Ghats (12°15'N; 75°37'E, 150 m elev.). During the day, *B. paritalis* retreats inside tree crevices or buttresses of live trees and dead wood ca. 0.3–0.6 m above ground. During the first hours of the night it emerges from this retreat to feed and mate. Between 1900–1930 h the toads emerge from the crevices adjacent to a stream and either enter the water or perch on rocks in the flowing stream. A few males arrive early and began calling, afterwards

many males emerge from the hideouts and join the calling group. This retreat habitat and calling behavior has not been reported for *B. paritalis*.

COCHRANELLA ALBOMACULATA (White-spotted Cochran Frog). **PREDATION**. Predation on adult anuran amphibians by invertebrates, especially by spiders (e.g., Blackburn et al. 2002. Herpetol. Rev. 33:299; Formanowicz et al. 1981. Herpetologica 37:125–129; Jansen and Schulze 2008. Herpetol. Rev. 39:459; Pontes et al. 2009. Herpetol. Rev. 40:71), but also by crabs (Duellman and Trueb 1986. Biology of Amphibians. The Johns Hopkins University Press. Baltimore and London), or bugs (Toledo 2003. Phyllomedusa 2:105–108) have been reported several times. Herein we report, to our knowledge, the first account of a whip scorpion (Amblypygi) feeding on a glass frog.

At 2200 h on 31 March 2009, at Cerro Negro, Veraguas Province, Panama (08.569°N, 81.097°W; 770 m elev.), we detected a large whip scorpion holding an almost digested female *Cochranella albomaculata* between its chelicerae. The whip scorpion was sitting on a rock, amidst a small mountain stream. At the time of observation all that remained of the frog were one leg and a clutch of eggs that poured out of the frogs remains (Fig. 1).

Amblypygi are not frequently reported as predators of frogs (Armas 2001. Revista Ibérica de Aracnología 3:87–88), nevertheless they might play an important role as predators of glass frogs. White-spotted Cochran Frogs are known to call from rocks in the stream during drier periods, whereas they prefer riparian vegetation during wet periods (Kubicki 2007. Glass Frogs of Costa Rica. Editorial INBio. Santo Domingo de Heredia, Costa Rica). Therefore the dry season is when whip scorpions might encounter these frogs frequently, as both seek out humidity on rocks near streams.

We thank Arcadio Carrizo and Smelin Abrego for their support during field work. This note is based upon work funded to AH by the FAZIT-Stiftung, and to SL by the Studienstiftung des deutschen Volkes.

DENDROBATES PUMILIO (Strawberry Poison-dart Frog). **COLORATION.** *Dendrobates pumilio* of Central America is noted for its exceptionally high level of color polymorphism (Savage 2002. The Amphibians and Reptiles of Costa Rica. Univ. Chicago Press, Chicago and London. 954 pp.). For decades this species has been the focus of numerous studies to elucidate the function, evolution, and maintenance of this color variation (Wang and Shaffer 2008. Evolution 62:2742–2759). An integral aspect of this research is to develop a detailed knowledge of the geographical range and description of all the color morphs.

The purpose of this note is to expose the existence of a previously unknown population of *D. pumilio* that differ from previously described populations. The existence of this population is based on numerous individuals that were consistently encountered during the years of 2005–2007, while the author was conducting unrelated research in the region. This new color morph is all blue, similar to the previously described morph found in the Cerro Brujo region, but has the large black spotting on the dorsum like those morphs found on Bastimentos (Fig. 1).

Individuals from this population were encountered on the mainland of the Bocas del Toro Province, Panama in the foothills between the Rio Changuinola and the Rio Risco within the vicinity of 9.218863°N, 82.460632°W. Although individuals of the nominate color morph were often encountered in adjacent areas along the Rio Changuinola, the two morphs were never seen within the area.

COLOR REPRODUCTION SUPPORTED BY THE THOMAS BEAUVAIS FUND

FIG. 1. The newly discovered color morph of *Dendrobates pumilio* differs from the nominate color form in being uniformly dark blue with large black spots on the dorsum.

DENDROPSOPHUS MICROCEPHALUS (Yellow Treefrog). **PREDATION.** Many frog species group together in a chorus to increase their mating success; however a significant risk they face in doing so is an increased detection by predators (Ryan et al. 1981. Behav. Ecol. Sociobiol. 8:273–278; Wells and Taigen 1989. Behav. Ecol. Sociobiol. 25:13–22) as olfactory, auditory, and vibratory signals are substantially increased in choruses. Anuran chorus behavior is prevalent due to the high probability of attracting a mate relative to calling alone (Ryan et al. 1981, *op. cit.*). Herein we report observations of predation on *D. microcephalus* by the Cat-eyed Snake *Leptodeira septentrionalis* in the vicinity of Las Cuevas Research Station (16.71667°N 88.9833°W), within the Chiquibul Forest Reserve, Belize. The advertisement call of this frog is generally described as a "creek-eek-eek" (Duellman 1970. The Hylid Frogs of Middle America Vol. 1. Monograph Mus. Nat. Hist., Univ. Kansas). On 6 Aug 2008 at ca. 2100 h, we heard a squeak-like repetitious call, differing substantially from the advertisement call: this call was higher pitched and although not analyzed, call rate seemed constant. Additionally, these calls were not triggered by conspecific call bouts as is generally observed in *D. microcephalus* (Schwartz and Wells 1985. Copeia 1985:27–38). Upon locating the source in the pond vegetation (a mixture of sedges and shrubs), we discovered that a male *D. microcephalus* had been attacked by a *L. septentrionalis* from the rear and was vocalizing what was most likely a distress call. The frog did not physically struggle as the snake consumed it, but did continue to vocalize until it was completely ingested. Ingestion took ca. seven minutes. Despite general knowledge of distress calls in anurans (Gerhardt 1994. Annu. Rev. Ecol. Syst. 24:293–324), this type of call remains undescribed in *D. microcephalus.* Moreover, little is known about predators of this species.

We thank the staff of Las Cuevas Research Station for support in the field. This work was carried out under permit from the Belize Forest Department and was approved by the UCLA Animal Care and Use Committee. This work was funded by a grant from the Columbus Zoo and Aquarium to KK.

DENDROPSOPHUS MINUTUS (NCN). **PREDATION**. Dragonfly larvae are commonly known to prey on small frogs and tadpoles (Caldwell et al. 1980. Oecologia 46:285–289), including species of Hylidae (McCollum and Leimberger 1997. Oecologia 109:615–621). On 28 Sept 2008 (ca. 2100 h), at Poço Azul, Brasília National Park, Federal District, Brazil (15º30'S, 47º50'W), we found a larval female odonate *Castoraeschna longfieldae* (50.5 mm length, catalogued at Museu Nacional do Rio de Janeiro [MNRJ]) preying on a tadpole of *Dendropsophus minutus* during a night of hard rainfall. This observation took place in a grassy pond where numerous anurans were heard calling. When captured, the odonate larva continued to grasp the tadpole. This is the first record of *C. longfieldae* preying on tadpoles. To accurately identify the dragonfly, we maintained the larva in the laboratory until metamorphosis (77.26 mm length). Other anurans in the area include *Rhinella schneideri*, *Phyllomedusa azurea*, *Hypsiboas lundii*, *Bokermannohyla pseudopseudis*, *Odontophrynus salvatori*, *Leptodactylus ocellatus*, and *L. furnarius*. Tadpoles of all these species may be potential prey to *C. longfieldae* and other larval odonates.

ELEUTHERODACTYLUS JOHNSTONEI (NCN). **MICROHABITAT**. *Eleutherodactylus johnstonei* has exhibited exceptional colonizing abilities, and exploits a wide variety of macro- and microhabitats, including outbuildings and shower stalls (Henderson and Powell 2009. Natural History of West Indian Reptiles and Amphibians. University Press of Florida, Gainesville). At 1930 h on 11 June 2009 at Lazy Lagoon Guest House in St George's, St. George Parish, Grenada, an adult *E. johnstonei* was found utilizing the top inside rim of a porcelain indoor toilet (Titon, 6.1 liters/flush). Its presence became known when the toilet was flushed, and the force of water from inside the upper rim caused the frog to descend into the bowl of the toilet; from there it vacated the toilet and escaped to the outside under a door. As business had been slow at Lazy Lagoon and this occurred at the end of the dry season, the frog was likely exploiting a convenient moist microhabitat. I am unaware of any previous report of *E. johnstonei* using the interior of an indoor toilet as a retreat.

HADDADUS BINOTATUS (Clay Robber Frog). **EGG CLUTCH**. *Haddadus binotatus* has direct development and a hatchling egg tooth (Hedges et al. 2008. Zootaxa 1737:1–182). During May 1987 in the Parque Nacional da Tijuca, an egg clutch of *H. binotatus* was found containing 14 eggs (Fig. 1). The eggs were collected, taken to the laboratory, and kept until hatching for identification. After hatching the material was fixed in 10% formalin and included in the amphibian collection of the Zoology Department of the Universidade Federal do Rio de Janeiro (ZUFRJ 3083). The egg clutch was found under a rotten tree trunk on the ground of the forest. The eggs were separated from each other in an area of 4.5 cm. A thin layer of substrate was stuck to the outer membrane of the egg. The eggs were large, ca. 10 mm, and two membranes were observed surrounding the embryo (Fig. 2). The embryos were a clear beige color when alive, they were all at the same stage of development,

FIG. 1. Egg clutch of *Haddadus binotatus* with 14 eggs found in the Parque Nacional da Tijuca.

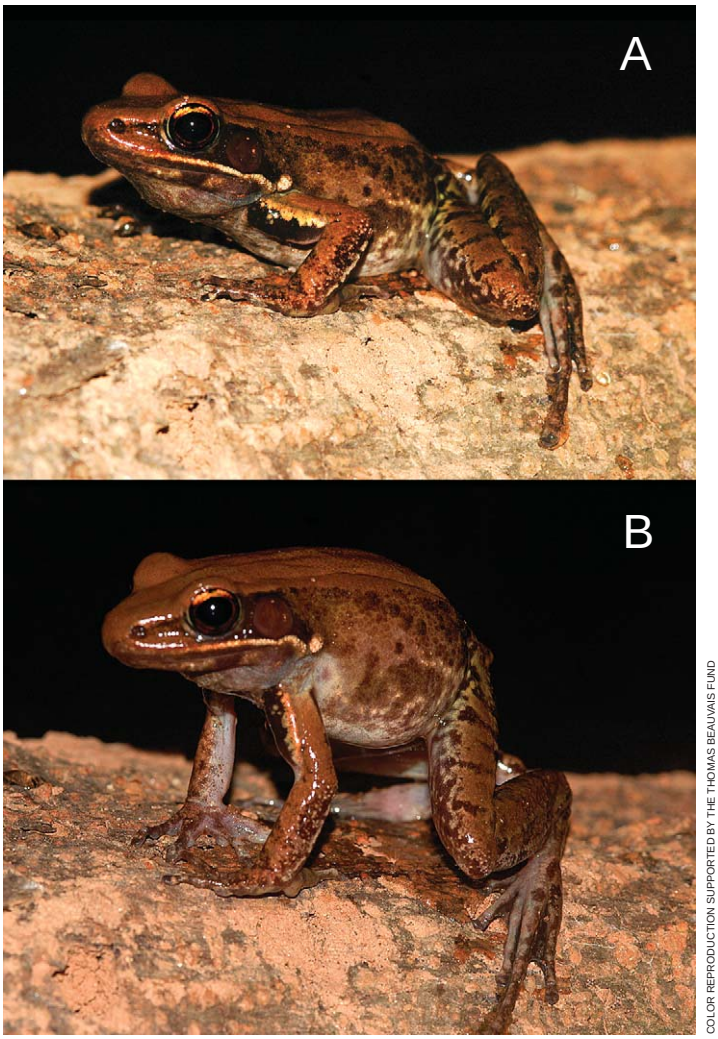

FIG. 2. Egg and embryo of *Haddadus binotatus* (about 10 mm).

and had a lot of yolk and a large, highly vascularized tail covering almost its entire body (Fig. 2). Near hatching, the characteristic egg tooth of the embryo could be observed. This tooth is keratinized and black in its distal portion as reported by Townsed and Stewart (1985 Copeia 1985:423–436) in *E. coqui* and *E. antillensis*, the egg tooth falling off shortly after hatching. The hatchling left the egg at ca. 9 mm SVL. The embryo tail of *Haddadus binotatus* covers almost its entire body, different from that of *Ischnocnema venancioi* (Izecksohn and Albuquerque 1972. Arq. Univ. Fed. Rur. Rio de Janeiro 2[1]:13–15), *I. guentheri* (Lynn and Lutz 1946. Bol. Mus. Nac. Zool. 71:1–46), *I. parva* (Lutz 1944. Bol. Mus. Nac. Zool. 15:1–30), and *E. coqui* (Townsed and Stewart 1985, *op. cit.*) which covers only part of the body. The tail is very vascularized, which suggests, as observed by Izecksohn and Albuquerque (1972, *op. cit.*), to be the main respiratory organ. Pombal (1999. Rev. Bras. Zool. 16[4]:967–979) observing the oviposition of *Brachycephalus ephipium*, showed that this species had parental care. The female rolled the eggs on the substrate to stick particles of substrate on its membrane to better camouflage them, to protect them from parasites, and to keep the embryos hydrated. It is possible that this behavior is the same in *H. binotatus* because the eggs were found covered by particles of substrate as observed by Pombal (1999, *op. cit.*). This is the first report of an egg clutch of *H. binotatus*.

Submitted by **PAULO NOGUEIRA COSTA** (e-mail: Nogpj@yahoo.com.br), and **SERGIO POSTCH DE CARVALHO E SILVA** (e-mail: sergio@biologia.ufrj.br), Departamento de Zoologia, Instituto de Biologia, Universidade Federal do Rio de Janeiro, Ilha do Fundão, 21.944-970, Rio de Janeiro, RJ, Brazil.

HYLARANA LEPTOGLOSSA (Long-tongued Frog). **DEFENSIVE BEHAVIOR.** *Hylarana leptoglossa* is an aquatic frog, inhabiting subtropical lowland forests and forming breeding aggregations on the edges of permanent, macrophyte-dominated

COLOR REPRODUCTION SUPPORTED BY THE THOMAS BEAUVAIS FUND

FIG. 1A. *Hylarana leptoglossa* in typical resting position. 1B. *Hylarana leptoglossa* in defensive posture.

waterbodies during the early monsoons (between the months of March to May). An adult male (Museum of Arya Vidyapeeth College, AVC 0943; SVL 60.5 mm) collected from near Lailad village (25.9320278°N, 91.7756944°E; 225 m elev.), Nongkhyllem Wildlife Sanctuary, East Khasi Hills, Meghalaya State, northeast India on 25 March 2009 displayed the following behavior as a response to handling during a photography session: all four limbs were planted on the substratum, while the body was greatly elevated, till the forelimbs were nearly vertical to the ground with the knee raised, the body raised > 50% depth of body (Figs. 1A–B). It maintained the position for ca. 10 secs each time.

Defensive postures are familiar methods of defense in anuran amphibians (review in Dodd 1976. Smithson. Herpetol. Inf. Serv. [37]:1–10), and were previously unreported in this species. The described posture results in elevated body position, presumably confusing potential predators. Another behavioral defense mechanism noticed was puffing of the body and of the gular region, although no glandular secretions or odor were detected.

LITHOBATES AREOLATUS CIRCULOSUS (Northern Crawfish Frog). **PREDATION.** The Eastern Hog-Nosed Snake, *Heterodon platyrhinos,* is generally considered to be specialized for eating toads (Bufonidae); it has been suggested that their enlarged posterior maxillary teeth assist in holding and deflating these prey (Edgren 1955. Herpetologica 11:105–17; Minton 2001. Amphibians and Reptiles of Indiana. Indiana Academy of Science. Indianapolis, Indiana. 404 pp.). However, *H. platyrhinos* is also known to consume other anuran species including several species of ranids (Edgren 1955, *op. cit.*; Platt 1960. Univ. Kansas Pub. Mus. Nat. Hist. 18:253–420). Here, we report predation by *H. platyrhinos* on *Lithobates areolatus circulosus*. To our knowledge, this is the first documentation of this snake species preying upon this frog species, which is in decline across portions of its northern range, including Indiana (Parris and Redmer 2005. *In* Lannoo [ed.] Amphibian Declines: Conservation Status of United States Species, pp. 526–528. Univ. Calif. Press, Berkeley, California).

On 14 May 2009 at 0750 h, an adult *H. platyrhinos* was observed at Hillenbrand State Fish and Wildlife Area in Greene County, Indiana (USA), regurgitating a recently consumed adult female *L. a. circulosus*. This frog was one of 19 implanted with transmitters (Model PD-2 Holohil Systems Ltd. [Carp, Ontario, Canada]) for a study of the movements and habitat use of this state endangered species. The snake (SVL 48.5 mm, TBL 62.1 mm, mass 130 g) was observed and captured near the frog's burrow. Upon being caught, the snake immediately performed a defensive display that included defecation and regurgitation; stomach contents included the frog implanted with the transmitter.

The *L. a. circulosus* (108 mm SVL) was first observed on 4 April 2009 in gravid condition (mass 134 g) while entering a semi-permanent breeding wetland. She left the wetland on 19 April 2009 after depositing her eggs (weight 90 g; Kinney, unpubl. data). After breeding, the frog traveled, over the course of 10 days, 730 m (straight line distance) NE to a burrow, which it inhabited for 14 days prior to being eaten. The regurgitated carcass was missing a portion of its head, suggesting the snake took the frog head on (and that there was resistance), a position consistent with occupancy of a burrow (JLH, pers. obs.), not an animal fleeing. The frog had been in the burrow the previous morning, and the carcass was fresh, suggesting that the frog had been eaten within the past 24 hours. Toads are uncommon at our study site. Only two *Anaxyrus fowleri* have been observed, another was heard calling (JLH; pers. obs.). None have been collected along 1100 m of drift fencing (184 buckets; four wetlands encircled; Kinney, unpubl. data). Low toad densities at our study site may result in *H. platyrhinos* predation on ranids.

LITHOBATES AREOLATUS CIRCULOSUS (Northern Crawfish Frog). **BREEDING.** *Lithobates a. circulosus* is declining throughout parts of its range and listed as state endangered in Indiana (Parris and Redmer 2005. *In* Lannoo [ed.] Amphibian Declines: Conservation Status of United States Species, pp. 526–528. Univ. Calif. Press, Berkeley, California.). We have been studying the breeding biology of this species in an attempt to understand factors contributing to recent declines (Minton 2001. Amphibians and Reptiles of Indiana. Indiana Academy of Science. Indianapolis, Indiana. 404 pp.).

Here we report an instance of atypical, perhaps satellite-like, breeding in *L. a. circulosus*. On 1 May 2009 at 0803 h, one of us (VCK) found an amplexed pair (Fig. 1) in a drift fence pit fall trap located at our study site, Hillenbrand State Fish and Wildlife Area in Greene County, Indiana, USA. The female was gravid. Both animals were pit-tagged prior to their release—still in amplexus—in the wetland, and were individually weighed and measured after separating and upon exiting. The male was 86 mm SVL, 74 g; the female was 101 mm SVL, 96 g, and was spent. There were three unusual components to these field observations: 1) This pair arrived 25 days after the end of peak breeding at this wetland, which occurred from 2 April 2009 through 5 April 2009 (VCK, unpubl. data). This was 26 days later than the previous last female, 20 days later than the previous last male. 2) The pair was in amplexus when found. While males and females occasionally occurred in the same bucket over the course of the breeding season, at no other time were *L. a. circulosus* (97 breeding animals total observed at our drift fences encircling two wetlands) found in amplexus before entering breeding wetlands. 3) The animals left the pond separately, a week apart (the female on 6 May 2009, the male on 14 May 2009), and upon exiting were found at the same bucket on the opposite side of the wetland where they had entered.

Explosive breeding in temperate amphibians such as *L. a. circulosus* typically involves males arriving early (Smith et al.

FIG. 1. Amplectant pair of *Lithobates areolatus circulosus* entering a breeding wetland. The female is gravid. Photograph by Vanessa C. Kinney.

1948. Amer. Midl. Nat. 39:608–614), and calling for competitive reasons (to establish dominance among males or access to favorable breeding sites) and to attract females. Once in the wetland, females are generally thought to exercise choice in determining mates or breeding sites (Wells 2008. The Ecology and Behavior of Amphibians. Univ. Chicago Press, Chicago. 1148 pp.). Alternately, satellite males, which tend to be smaller and younger, may sneak matings by remaining silent and intercepting females, avoiding competitive interactions with males and not affording females choices (Krebs and Davies 1978. Behavioural Ecology: An Evolutionary Approach. Sinauer, Sunderland, Massachusetts. 494 pp.; Wells 2008, *op. cit.*).

It is likely that neither male competition nor female choice occurred with this amplexed pair of *L. a. circulosus*. They came from a direction (east) with no known breeding wetlands (indeed, the wetland where they were found may be the easternmost extant breeding wetland for this species at this latitude). The next closest wetland in any direction is > 1 km away. It is possible that they coupled in this distant wetland and traveled overland in amplexus to the wetland where they were found; this would account for their tardiness. But at least eight other females bred at this second wetland, and there were no features of this wetland such as drying or the presence of fish that appeared to us to make it unfavorable. It seems more likely that the male intercepted the female on the way to the wetland where they were found—perhaps at some distance away, which, again, would account for their tardiness. If so, there was likely no calling involved in attracting this female and little opportunity for female choice. At 86 mm SVL, this male was not small (Parris and Redmer 2005. *op. cit.*); nevertheless, this observation suggests some form of previously undescribed alternate mating tactic, perhaps a satellite-type male behavior, in this species.

Submitted by **VANESSA C. KINNEY** (e-mail: vkinney1@indstate.edu) and **MICHAEL J. LANNOO** (e-mail: mlannoo@iupui.edu), Indiana Univ. School of Medicine-TH, Rm. 135 Holmstedt Hall-ISU, Terre Haute, Indiana 47809-9989, USA.

LITHOBATES NEOVOLCANICUS (Transverse Volcanic Leopard Frog). **DIET**. *Lithobates neovolcanicus* inhabits lakes and low streams in open areas surrounded by oak-pine forest and mesquite prairies throughout the Transverse Neovolcanic Belt (1500–2500 m elev.) across the states of Guanajuato, Jalisco, Michoacán, and México in central México. On 1 Dec 2008 at 1935 h we observed and photographed a *Lithobates neovolcanicus* (IBH-RF 027; 51 mm LHC), eating an *Anaxyrus punctatus* (Red-spotted Toad) in a small pond situated at Rio Las Lajitas (21.4932333°N, 99.961°W; 947 elev.), in the Tortugas locality at Xichú Municipality, Guanajuato, México. Other reports on the diet of *Lithobates zweifeli, L. catesbeianus, L. vaillanti,* and *L. brownorum* (Field and Beatty 2003. Herpetol. Rev. 34:228; Ramírez-Bautista and Lemos-Espinal 2004. Southwest. Nat. 49[3]:316–320; Mendoza-Estrada et al. 2008. Acta Zool. Mex. [n.s.] 24[1]:169–197) indicate that most species feed on invertebrates and terrestrial and aquatic vertebrates, including fish and tadpoles of *Lithobates* sp. *Lithobates vaillanti* was reported eating *Agalychnis callidryas* (Vaughan 2003. Herpetol. Rev. 34:238), but no reports on feeding habits of *L. neovolcanicus* occur in the literature.

Submitted by **ADRIANA JUDITH GONZÁLEZ HERNÁNDEZ, SAMUEL REYES SOSA,** and **VÍCTOR HUGO REYNOSO**, Colección Nacional de Anfibios y Reptiles, Instituto de Biología, Departamento de Zoología, Universidad Nacional Autónoma de México, Circuito Exterior s/n Ciudad Universitaria, México D.F. México C.P. 14510.

LITHOBATES ONCA (Relict Leopard Frog). **CANNIBALISTIC OOPHAGY**. Oophagy, the consumption of eggs, is not uncommon among anurans (Crump 1992. *In* Elgar and Crespi [eds.], Cannibalism: Ecology and Evolution Among Diverse Taxa, pp. 256–276. Oxford University Press, New York; Alford 2009. *In* McDiarmid and Altig [eds.], Tadpoles: the Biology of Anuran Larvae, pp. 240–278. Univ. Chicago Press, Chicago, Illinois; Gunzburger and Travis 2005. J. Herpetol. 39:547–571). It is one of many forms of cannibalism exhibited by amphibians, most commonly by the larval stages (Crump 1992, *op. cit*). The larvae of a number of hylids and dendrobatids that occur in various phytotelmons eat heterospecific and homospecific (trophic) eggs. The larvae of two species of *Lithobates* have been reported to be oophagous (*L. sylvatica* and *L. temporaria*), but cannibalistic oophagy has only been reported for *L. temporaria* (Alford 1999, *op. cit.* and Gunzberger and Travis 2005, *op. cit.*).

Homospecific oophagous activities by tadpoles of *Lithobates onca* were observed in two different canyons within Black Canyon, Clark Co., Nevada, USA. On the morning of 25 April 2008, I observed two large (7–9 cm total length, estimated Gosner [1960. Herpetologica 18:183–190] stages 34–36) tadpoles that initially appeared to be resting on a 1–2 day old egg clump of *L. onca* (terminology from Altig and McDiarmid 2007. Herpetol. Monogr. 21:1–32). The egg clump was within 20 cm of the shore, about 5 cm below the water surface, and attached to overhanging Bermuda Grass (*Cynodon* sp.). As I observed for about 7 min, it became evident that the tadpoles were eating the eggs. The tadpoles wriggled and tore at the eggs at the top and sides of the clump. There was a second, recently-laid clump within 30 cm of the feeding tadpoles that was also attached to overhanging grass. The permanent pool was in a natural warm-water spring system; the pool measured 6 × 4 m with a maximum depth of about 1 m. The substrate was

silt over bedrock. There was no emergent or submergent aquatic vegetation, but the bottom did have visible algal growth. Water temperature was 22° C. Five *L. onca* tadpoles of similar size to those seen on the eggs were in the pool. When I returned to the site on 27 April 2008, there was no evidence of either egg clump, and no hatchlings were seen in the pool. Hatchlings were not expected to have already hatched because it takes about 5-7 days for embryos of *L. onca* to hatch at this temperature (personal observation).

At about 1900 h on 28 April 2008, in a second canyon off Black Canyon, *L. onca* tadpoles were observed eating a later stage egg clump (Gosner Stages 15–18) of *L. onca*. In a permanent pool filled by flow from warm-water springs in the system, three *L. onca* tadpoles about 7–9 cm total length, at Gosner stages 34-36, were tearing at the eggs. The pool measured about 2 x 3 m with a maximum depth of 0.4 m. Pool substrate was cobble, silt and bedrock with visible algal growth. Water temperature was 21° C. There was a smaller, more recently oviposited egg clump of *L. onca* in the pool about 20 cm from the eggs being consumed. Both egg groups were attached to *Typha* sp. at 10 and 5 cm below the water surface. On 1 May 2008, the first egg clump was absent; the majority of the jelly of the second group remained, but the embryos were absent. The egg membranes were torn and appeared partially consumed. The observations of the state of the egg masses and absent embryos were consistent with those described by Petranka and Thomas (1995. Anim. Behav. 50:731-739). There were no hatchlings seen in the pool, but as seen at the previous site, these also were not expected to have hatched in such a short period. In both cases, no other predators were seen in the pool, nor were there tracks or prints seen around the shoreline of the pool.

Typically, cannibalism is expected to occur under conditions including high density and low food availability (Caldwell and Carminoza de Araujo. 1998. Biotropica 30:92-103). Potential benefits of oophagy include elimination of potential competitors, increasing resources available for survivors, and energy-rich nutrients from the eggs in the form of calcium and phosphorus, necessary components for proper skeletal development (Crump 1983. Am. Nat. 121:281-287). Neither high density nor low food availability appeared to be factors in the two pools in which I observed cannibalistic oophagy exhibited by *L. onca*. It has been suggested that explosive breeding in amphibians is a response to cannibalism by reducing differences in developmental stages and therefore reducing the opportunity for cannibalism to occur. *Lithobates onca* is not an explosive breeder, but rather has a prolonged breeding season extending for several months (Bradford et al. in Lannoo (ed) 2005. Amphibian Declines. Univ. California Press: Berkeley, pp. 567-568; personal observation). While Fox (2008. Herpetol. Rev. 39:151-154) reported only early stage *Spea intermontana* tadpoles fed on conspecific hatching tadpoles, the observations reported here were more in line with the reports from Crump (1983. *op. cit*.) that no tadpoles of *Hyla pseudopuma* under Gosner 35 were observed to be cannibalistic. There was no apparent fungal or algal growth on the eggs or developing embryos of *L. onca* that were being cannibalized, unlike those of *Spea* (Fox 2008. *op. cit.)*. Unlike most other oophagous tadpoles, the tadpoles of *L. onca* are not morphologically specialized for eating eggs. The mouth is relatively small with well developed keratinized jaw sheaths that have only small serrations; oophagous larvae typically have powerful jaws, enlarged jaw sheaths and broad oral labia. The tadpoles of *L. onca* also lack the modified, shortened intestinal tract found in other oophagous larval anurans, suggesting that the tadpoles of *L. onca* are only opportunistically oophagous.

Crump (1990. Copeia.1990:560–564) and Wildy et al. (1998. J. Herpetol. 32:286–289) reported that cannibalism resulted in enhanced growth of larval treefrogs and larval salamanders. We currently have no data to indicate that this is the case for tadpoles of *L. onca.* Several species of *Lithobates* have been reported to consume heterospecific eggs (Gunzberger and Travis 2005, *op. cit.*). *Lithobates onca* currently co-occur with *Bufo woodhousii*, *B. punctatus*, and *H. arenicolor* (unpubl. data). It would be interesting to observe whether the opportunistically cannibalistic oophagous tadpoles of *L. onca* are also opportunistically heterospecific oophagous.

These observations were made while conducting conservation efforts supported by Lake Mead National Recreation Area, National Park Service. I thank R. Altig for helpful comments on this note.

Submitted by **DANA L. DRAKE**, Public Lands Institute, University of Nevada Las Vegas, 4505 S. Maryland Pkwy, Box 452040, Las Vegas, Nevada 89154, USA; e-mail: ranita_bella@hotmail.com.

LITORIA CAERULEA (Green Treefrog). **SAUROPHAGY**. *Litoria caerulea* is a large hylid frog from northeastern Australia (Cogger 2000. Reptiles and Amphibians of Australia. 6th edition. Ralph Curtis Publishing, Sanibel, Florida. 808 pp.). *Litoria caerulea* are known to be opportunistic predators, even capable of eating small rats (Tyler 1994. Australian Frogs: A Natural History. Cornell Univ. Press, 51 pp.). Reports of reptiles being eaten in the field by *L. caerulea* are rare. During the evening of 16 Sept 2006 I observed a gecko (*Hemidactylus frenatus*) at ca. 2 m height in a palm tree on the campus of James Cook University in Townsville, Queensland, Australia. *Hemidactylus frenatus* is native to Southeast Asia and is introduced into Australia (Wilson 2005. A Field Guide to Reptiles of Queensland. New Holland Publishers, 45 pp.). While observing the gecko, I watched a *L. caerulea* jump from a higher location in the palm and attack the gecko. The gecko was grabbed near its hind legs and bit the frog before being eaten. Photographs were taken during the event and deposited in the digital image collection at the Amphibian and Reptile Diversity Research Center at the University of Texas at Arlington (UTADC 4007). This is the first record of saurophagy in *L. caerulea*.

I thank J. A. Campbell for cataloguing the digital image at UTA, L. Schwarzkopf for confirming the identification of the gecko, and R. C. Jadin for comments on this note.

LITORIA CYCLORHYNCHA (Spotted Thighed Frog). **SALINE HABITAT**. With some rare exceptions (e.g., Balinsky 1981. J. Exp. Zool. 215:335–350) anurans are generally intolerant of salt water, particularly in the larval stage. For example, recent studies in Australia reported upper conductivity tolerance limits in the field for tadpoles between 10^3 and 10^4 μS cm^{-1} (2–10% sea water)

for six common frog species found in waters affected by secondary salinisation in western Victoria, Australia (Smith et al. 2007. Freshwater Biol. 52:75–84). During a recent survey of the water quality and biodiversity values of the rivers of the South Coast Region undertaken by the Centre of Excellence in Natural Resource Management, University of Western Australia, tadpoles were collected in waters with comparatively high salt loads at sites on the Twertup Creek system, Fitzgerald River: 20.7 mS cm^{-1} (salinity of 12.4 ppt, 35% seawater: site C2, Mum's Creek, 33.780617°S, 119.2975767°E, 15 Jan, 21 tadpoles) and 22.2 mS cm^{-1} (salinity of 13.37 ppt, 38% seawater: site JC8, on Jacup Creek, 33.749267°S, 119.209667°E, 12 Jan, 1 tadpole). Tadpoles were identified as *Litoria cyclorhyncha* using Main (1965. Frogs of Southwestern Australia. Western Australian Naturalists' Club, Perth, Australia. 73 pp.) and Anstis (2002. Tadpoles of South-eastern Australia. Reed New Holland, Sydney, Australia. 281 pp.). At C2 tadpoles were at Gosner Stages 24 (1), 25(14), 26 (4), 28 (1) and 37 (1). At JC8 the single tadpole collected was at Gosner Stage 37 and had a total length of 64 mm. The late stage of development for some tadpoles at both sites suggests an extended period exposed to high salinities. The cluster of tadpoles at early post-hatching stages at C2 might indicate a recent breeding event—presumably also in relatively saline water. There is variation in salinity at these sites. In late spring sampling at the same sites (11 and 12 Nov 2008) salinities were much higher at 51.32 mS cm^{-1} (C2) and 48.79 mS cm^{-1} (JC8) (33.79 and 31.7 ppt, 86 and 91% seawater). Local rainfall and runoff reduce salinities and there was rainfall in the period November to January: November, 89.8 mm, 19 rain days, maximum daily fall 17.4 mm; December, 65 mm, 12 rain days, maximum daily fall 23.4 mm; January, 16.4 mm, 4 rain days, maximum daily fall 10.0 mm (rainfall data for Jacup, ca. 5 km WNW of sampling sites, from http://www.bom.gov.au/climate/dwo/IDCJDW6058.latest.shtml, accessed 16 April 2009).

On 8 Sept 2008 an adult frog jumped into a pool on Twertup Creek (site TWE03, 33.9156°S, 119.19808°E). The frog was captured in the pool and identified as *L. cyclorhynca*. Water in the pool had a salinity of 56.9 mS cm^{-1} (salinity of 37.4 ppt, 107% seawater). The frog jumped back into the pool again when released on granite rocks on the bank. The sound made when the frog jumped into the pool was frequently heard along this hypersaline creek system suggesting *L. cyclorhyncha* may commonly and voluntarily enter highly saline waters.

Salt levels in these tributaries of the Fitzgerald River system are partly elevated due to secondary salinity generated by clearing of native vegetation but the streams also have naturally high salinities as this region has a long, geological history of primary, natural salinity in a variety of water bodies (e.g., at least 3 million years; George et al. 2008. Aust. J. Soil. Res. 46:751–767). Our data suggest these sites might be highly saline when this species breeds in spring and summer (Tyler et al 2001. Frogs of Western Australia. WA Museum, Perth, Western Australia). Anurans can have well-developed capacities to distinguish salinities (Haramura 2008. Copeia 2008:64–67) so the use of saline waters is unlikely to be a mistake and, both adults and tadpoles of *L. cyclorhyncha* can clearly tolerate elevated salinity levels. Tadpoles of a closely related species, *L. aurea* from eastern Australia (Burns and Crayn 2006. Mol. Phylog. Evol. 39:573–579), have been reported in water between 5 and 15% seawater (Christy and Dickman 2002. Amphibia-Reptilia 23:1–11) but not in salinities as high as reported here.

If this truly is a high salinity tolerance in *L. cyclorhyncha* this might reflect natural tolerance evolved during extended exposure to naturally saline waters (George et al. 2008, *op. cit.***)** which may have been accentuated during earlier periods of lower rainfall in south-western Australian (e.g., in the Plio-Pleistocene; Byrne 2008. Quaternary Sci. Rev. 27:2576–2585). Secondary salinization has generally been seen as having a negative impact on amphibians in the field (e.g., Smith et al 2007, *op. cit.*) but our observations suggest that one Australian frog species may have a much higher salinity tolerance than anticipated. More extensive field work is required to clarify how generally *L. cyclorhyncha* uses saline waters and what life history stages can persist in saline water.

Submitted by **GERALDINE JANICKE**, Centre of Excellence in Natural Resource Management (CENRM), Univ. Western Australia, Albany, WA 6330, Australia; and **J DALE ROBERTS**, CENRM and School of Animal Biology M092, University of Western Australia, Nedlands, WA 6009, Australia.

MELANOPHRYNISCUS MOREIRAE (Maldonado Red-bellied Toad)**. DEFENSIVE BEHAVIOR.** When threatened, many amphibians show a defensive behavior called unken reflex (Duellman and Trueb 1994. Biology of Amphibians. McGraw Hill, New York. 670 pp.). In this behavior, the individual arches its back, lifting the head and the posterior part of the body while remaining motionless. The forelegs are brought forward and upward and the hind legs are flexed upward, showing the aposematic coloration of the throat and limbs as described and figured by Noble (1951. Biology of the Amphibia. McGraw Hill, New York; p. 381, fig. 131). However, nontoxic and drab colored species may also exhibit this posture (Noble 1951, *op. cit.;* Firschein 1951. Copeia 1951[1]:74).

The bufonid genus *Melanophryniscus* contains 25 species, all distributed in southeastern South America (Frost 2009. Amphibian Species of the World. An Online Reference. Version 5.3 <http://research.amnh.org/herpetology/amphibia/index.php>. 15 Nov 2009; Céspedez 2008. Facena 24:35-48). *Melanophryniscus* species are arranged in three phenetic groups: *M. stelzneri* group, *M. tumifrons* group, and *M. moreirae* group (Cruz and Caramaschi 2003. Bol. Mus. Nac. [N.S.] Zool. 500:1–11). All species have aposematic coloration (e.g., Cruz and Caramaschi 2003, *op. cit.*; Kwet et al. 2005. Salamandra 41[1/2]:3–20). Fernández (1927. Bol. Acad. Nac. Cienc. Córdoba, 29:271–320) was the first to report unken reflex for *Melanophryniscus* (*M. stelzneri*) and this behavior has been observed in nine other species—six in *M. stelzneri* group and three in *M. tumifrons* group: *M. dorsalis, M. montevidensis, M. cupreuscapularis* and *M. pachyrhynus* (Kwet et al. 2005, *op. cit.*), *M. krauczuki*, and *M. atroluteus* (Baldo and Basso 2004. J. Herpetol. 38:140–150), *M. rubriventris* (Laurent 1973. Acta Zool. Lilloana 26[23]:319–334), *M. devincenzii* (Manzano et al. 2004. Inst. Sup. Correl. Geol. Miscellánea 12:271–290), and *M. orejasmirandai* (Kolenc et al. 2003. Aquamar, Madrid 5[30]:16–21).

During a long-term study carried out at the plateau of Parque Nacional do Itatiaia (between 22.3095278°S, 44.6739444°W and 22.38975°S, 44.6723611°W), 1950–2400 m elev., states of Minas

Gerais and Rio de Janeiro, Brazil, nine adults of *Melanophryniscus moreirae* (seven males and two females) were observed exhibiting unken reflex in potentially threatening situations such as fall (N = 2), handling (N = 6), and accidental trampling (N = 1), exposing the bright red coloration of limbs and throat. All nine individuals also exhibited the posture when their backs were pressed with a finger against our hands, vegetation, or other substrate, as shown in Fig. 1. The observations were made between September–December (Spring–Summer) during 2005–2008 and in October 2009. The individual observed in 2009 was a male and displayed the behavior during amplexus (Fig. 2), persisting even when the female moved. After a few minutes the male released his hold but still displayed the unken reflex behavior. This is the first report of unken reflex in *M. moreirae* group and, as far as we know, the first record for unken reflex behavior in a paired amphibian.

ODONTOPHRYNUS cf. AMERICANUS (NCN). **PREDATION** Despite the great variety of taxa known to prey on amphibians, records from Argentina are scarce. Current information on predation of *Odontophrynus* spp. is lacking. Here we provide with the first report of *Liophis vanzolinii* (Colubridae) predating *Odontophrynus cf. americanus*. On 12 Oct 2008 at 1520 h at Estancia Las Verbenas, Valle de Pancanta (WGS84, 32.8666667°S, 66.1°W; 1650 m elev.), Central Ranges of San Luis Province, Argentina, we observed an adult *L. vanzolinii* (460 mm TL) predating an *O. cf. americanus* (43 mm SVL). This interaction was observed in a pasture near a rocky stream bordered by *Cortaderia selloana* grass. These specimens were collected and immediately after capture, the snake released the frog, which died within a few minutes.

These specimens are deposited in the Herpetological Collection of Universidad Nacional de San Juan (UNSJ-1000 *Odontophrynus cf. americanus*; UNSJ-1002 *Liophis vanzolinii*). Both species are common in this area and it is possible that this interaction occurs on a regular basis. This observation suggests that *L. vanzolinii* is a natural predator of *O. cf. americanus* and that the "blue" skin toxins (unreported blue coloration of toxin secretion; Laspiur and Buff, pers. obs.) of *O. cf. americanus* might not be an effective defense against *L. vanzolinii*. We thank Sol Acosta for help with field work and review of this note.

PHYLLODYTES LUTEOLUS (Yellow Heart-tongued Frog) **PREDATION**. Spiders and invertebrates are well known predators of frogs (Formanowicz et al. 1981. Herpetologica 37:125–129; Prado and Borgo 2003. Herpetol. Rev. 34:238–239; Toledo 2005. Herpetol. Rev. 36:395–400; Menin et al. 2005. Phyllomedusa 4[1]:39–47). On 13 April 2006 at 2015 h we observed predation of *Phyllodytes luteolus* by the spider *Phoneutria* cf *bahiensis* (Fig. 1). This observation occurred on a terrestrial bromeliad in the coastal ecosystem at Belmonte Municipality, Bahia, Brazil. This is the first

FIG. 1. *Phyllodytes luteolus* being predated for spider. Photo by Thais Silva.

report of spider predation on *Phyllodytes* sp. in Brazil (Menin et al. 2005, *op. cit*. and Toledo 2005, *op. cit*).

PHYSALAEMUS BILIGONIGERUS (NCN). **PREDATION.** As amphibians undergo ontogeny, their relative vulnerability to predators can shift with their life stage (Wells 2007. Ecology and Behavior of Amphibians. Univ. Chicago Press, Chicago, Illinois. 1148 pp.). Herein I document two predation events of *Physalaemus biligonigerus* at two different life stages; the first by a giant water bug (Belostomatidae) on an adult frog, and the second by a domestic pig (*Sus scofra domestica*) on a nest.

Giant water bugs are known to be major invertebrate predators of post-metamorphic anurans (Toledo 2005. Herpetol. Rev. 36:395–400). On 21 March 2009 at 2045 h, I observed a large belostomatid (body length ca. 75 mm) consuming a *P. biligonigerus* in a temporary pond in the Isoceño community of Yapiroa, Provincia Cordilleria, Departmento Santa Cruz, Bolivia (WGS 84, 19.6000°S, 62.5667°W). The giant water bug and the *P. biligonigerus* were ca. 200 mm from the shore of the pond. When I approached the pair, the belostomatid released the frog and swam into deeper water and I was unable to identify it to species. I retrieved the dead frog from the surface of the water (adult male; SVL 39 mm) and observed a puncture wound on its venter. Male *P. biligonigerus* call from the shallows close to the edge of a pond or from the middle of temporary pools (up to 20 cm deep; Schalk, unpubl. data). As with other *Physalaemus* species, male *P. biligonigerus* call from the surface of the water and generate waves that may attract aquatic predators (Toledo 2003. Phyllomedusa 2:105–108; pers. obs.).

Physalaemus biligonigerus construct foam nests to protect eggs from desiccation and predators (Prado et al. 2005. Amphibia-Reptilia. 26:211–221). These nests float on the water's surface and are generally deposited near emergent vegetation close to the pond's shore (pers. obs.). On 24 March 2009 at 1430 h, I observed an adult domestic pig eat a foam nest of a *P. biligonigerus* in the same temporary pond described above. The pig took the entire nest in its mouth and proceeded to chew it with smaller pieces of foam falling out of its mouth. After swallowing the large piece, it proceeded to eat the smaller pieces of foam floating in the water. There were no other *P. biligonigerus* nests in the pond. After consuming the nest, the pig walked into the surrounding forest. It is uncertain whether foam nests are regularly consumed by pigs in this region. My observations of 55 nests from February to March 2009 indicate that many, if not most, foam nests are not consumed or disrupted by pigs.

PSEUDACRIS REGILLA (Northern Pacific Treefrog). **CAVITY USE.** Frogs of the family Hylidae use a variety of natural refuges, such as interstices among rocks (*Hyla macrocephala*, McIntyre 2003. Herpetol. Rev. 34:51) and cavities in standing trees (*H. japonica*, Kojima and Osawa 2003. Bull. Herpetol. Soc. Japan 2003:1–2; *H. cinerea* and *H. versicolor/chrysocelis*; McComb and Noble 1981. Wildl. Soc. Bull. 9:261–267). In the Pacific Northwest, *Pseudacris regilla* have been found in arboreal nests of tree voles (*Arborimus* spp.; Forsman and Swingle 2007. Herpetol. Cons. Biol. 2:113–118). Besides anecdotal reports of use of cover objects (Jameson 1957. Copeia 1957:221–228; Weitzel and Panik 1993. Great Basin Nat. 53:379–384) and "log crevices" (Nussbaum et al. 1983. Amphibians and Reptiles of the Pacific Northwest. Univ. Idaho Press, Moscow. 332 pp.), we found little information on use of natural cavities by *P. regilla*. Here, we report extensive use by *P. regilla* of pre-existing cavities in logs around a breeding pond in northeastern Oregon, USA.

We made our observations at a shallow pond 20.5 km SSW of Baker City, Oregon (44.6165°N, 117.9583°W; elev. 1597 m). This pond hosts large breeding populations of *P. regilla* and *Ambystoma macrodactylum*. The pond is within an opening in a forest comprised mainly of Ponderosa Pine (*Pinus ponderosa*). The understory is sparse grasses with an abundance of downed branches and logs. The pond fills with water in spring to reach ca. 1 m deep and 40 m × 40 m in surface area. By late summer, the

pond was reduced to ca. 0.2 m deep (8 m × 10 m surface area) when we made our observations. Vegetation on the exposed, shallowly sloping benches ringing the summer pool was grasses and sedges matted by livestock use. The receded water left 28 large logs (> 2m long) stranded around the exposed benches and concentrated in the NW quadrant of the pond. Most logs had little to no bark, and met the definition of decay Structure Class 2 (on ground, missing some limbs and bark, minor decay; Bull et al. 1997. Trees and logs important to wildlife in the interior Columbia River basin. USDA Forest Service Report PNW-GTR-391, 55 pp.).

During a morning (0930–1100 h) survey on 12 August 2005, we observed at least 80 small *P. regilla* wedged into cracks and hollows in one of the larger logs (hereafter 'Log A'; ca. 5 m long × 0.5 m diam.). Our visual assessment was that all of these *P. regilla* were between 17 and 21mm SVL, which is consistent with them having transformed in July and August of that same summer. Log A was in the NW quadrant and had its long axis running NE/SW so it received direct morning insolation along its length by the end of our survey. Log A was the closest (ca. 0.75 m) of the logs to the water. We observed at least 15 cases where 2–4 frogs were packed together in the same cavity (Fig. 1). We noted 4 occasions at Log A where a partially exposed frog emerged from a deep cavity followed by a second frog that emerged from an obscured position further inside the log. Over the course of our survey, frogs moved progressively out of cavities and dispersed over the southeast-facing surface of the log. By the time we departed, frogs had emerged from almost all the cavities occupied previously, and we observed several frogs on the ground around the log where we had not observed frogs previously.

We saw one *P. regilla* emerge from a cavity in a second log ('Log B', 0.6 m long, 0.4 m diam.) located 24 m NE of the small pool. Attached bark confirmed this log as *P. ponderosa*. We counted 10 holes in this log, all of which had sharp edges and were roughly oval in shape (mean diam.= 14 ± 1.6 SE mm). We were able to insert a finger into a few of the holes and determine that they enlarge a little below the surface.

Close inspection revealed *P. regilla* emerging from cavities in 3 of 10 other logs along the ponds northern benches near Log A and Log B. Of the logs we inspected, Log A appeared to have the most cavities. The hollows, grooves, and holes that were occupied in Log A appeared to be cracks and insect cavities whose size and shape had been altered by natural decay and possibly fire. Cavities in Log A measured 8–15 mm in diameter and of the 6 we probed with twigs, most extended at least 110 mm into the log. Cavities occupied by frogs in other logs typically had entries that were oval and measured 10–15 mm in diameter.

FIG. 1. Recently metamorphosed *Pseudacris regilla* clustered into, and emerging from, cavities in a decaying log.

The use of pre-existing burrows for moisture regulation, predator avoidance, aestivation, and thermoregulation has been documented for many amphibians (Duellman and Treub 1986. Biology of Amphibians. J. Hopkins University Press, Baltimore, Maryland. 670 pp.).

Our observations suggest that cavities in downed wood can be used extensively by recently-transformed *P. regilla* near their breeding sites. Retreats such as those we describe could be valuable for a number of reasons, including serving as refuges near water sources for rehydration during the dry season, thermally buffered retreats during cold nights, or protection from some predators.

Submitted by **BROME McCREARY** (e-mail: brome_mccreary@usgs.gov), and **CHRISTOPHER A. PEARL**, U.S. Geological Survey, Forest and Rangeland Ecosystem Science Center, 3200 SW Jefferson Way, Corvallis, Oregon 97331, USA.

PSEUDACRIS REGILLA (Northern Pacific Treefrog)**. PREDATION.** Mallards (*Anas platyrhynchos*) are omnivorous ducks which have been observed eating a number of frog species, including *Rana aurora, R. boylii, R. sylvatica,* and *R. temporaria* (Hayes and Rombough 2004. Herpetol. Rev. 35:375–376; Rombough et al. 2005. Herpetol. Rev. 36:438–439). However, *Pseudacris regilla* has not been reported as prey.

On 17 Jan 2009, while hunting ducks on the Willamette River near St. Paul, Marion County, Oregon, we shot a hen mallard as it flew into our decoys on a flooded gravel bar. Immediately after death, an adult *P. regilla* (44.5 mm SVL, 5.5 g, gravid female) emerged from the duck's mouth and hopped across the floor of our boat. The frog was collected, examined, and found to have no visible injuries. It was placed in a container for observation and was still alive the next day. The crop and digestive tract of the duck was removed and examined; it contained sand and a small amount of plant matter.

Pseudacris regilla in the northern Willamette Valley typically gather for spawning during late January and early February, and mallards in this area have been observed feeding on *P. regilla* life stages (eggs, adult frogs) at spawning sites (C. Rombough, unpubl. data). The mallard hen described here was collected at 0930 h, when air temperature was –2.2° C, and the surfaces of still and slowly flowing waters in the area were frozen. *Pseudacris regilla* in this area had begun breeding a week before this observation (10 Jan 2009). We speculate that the frog had been in a torpid state, possibly under ice at the edge of a breeding pool, when the duck consumed it, and that the post-mortem spasms of the duck assisted in its escape from the bird's crop.

Submitted by **CHRIS ROMBOUGH**, 2545 Columbia Blvd., Apt #64, St. Helens, Oregon 97051, USA (e-mail: rambo2718@yahoo.com); and **MATT BRADLEY**, 16646 Butteville Road NE, Woodburn, Oregon 97071, USA.

RANA CASCADAE (Cascades Frog). **NECROGAMY.** Necrogamy has been previously documented in *Rana boylii* (Bettaso et al. 2008. Herpetol. Rev. 39:462). Herein we report a similar mating observation in *R. cascadae* while conducting egg mass surveys at Deep Creek Basin, Trinity Alps Wilderness, Trinity County, California, USA. On 18 May 2009 at 1326 h, an adult male *R. cascadae* (60.6 mm SVL) was observed in amplexus with a deceased gravid female *R. cascadae* (77.3 mm SVL) ca 20 cm underwater in a shallow stream alcove (Fig. 1). The deceased female *R. cascadae* was partially decomposed and a film of fungal hyphae covered both sides of the body. The male *R. cascadae* appeared to be in good condition upon inspection after removal from the deceased female. This behavior could allow negative population effects for *R. cascadae* by reducing overall male courtship availability during their brief and explosive breeding seasons. Additionally, this behavior could have negative implications with direct transmission of diseases.

FIG. 1. Male *Rana cascadae* in amplexus with deceased conspecific in Deep Creek basin, Trinity Alps Wilderness, California.

Submitted by **JUSTIN M. GARWOOD**, California Department of Fish and Game, 50 Ericson Court, Arcata, California 95521, USA (e-mail: jgarwood@dfg.ca.gov); and **COLIN W. ANDERSON**, Department of Fisheries Biology, Humboldt State University, 1 Harpst Street, Arcata, California 95521, USA.

RANA CATESBEIANA (American Bullfrog)**. PREDATION.** The Osprey, *Pandion haliaetus*, is a large (to 1.8 m wingspan) raptor whose breeding range includes western North America (Udvardy 1997. National Audubon Society Field Guide to North American Birds. Chanticleer Press, New York. 822 pp.). The osprey's diet consists almost exclusively of fish, although other vertebrates, including amphibians, are occasionally taken as prey (Birds of North America, Cornell Lab of Ornithology: http://bna.birds.cornell.edu/BNA/). However, taxon-specific accounts of amphibians as items of osprey diet are lacking. I here provide an account of osprey predation on *Rana catesbeiana*.

At 1300 h on 15 May 2007, I was watching male *R. catesbeiana* call and defend territories along the banks of a small (0.4 ha) farm pond in western Oregon, USA (WGS84, 50.08761°N, 51.6528°E). Frogs were calling while floating at the water's surface; their bright yellow throats were highly visible. Periodically, one would rush an intruding male from several meters away, grabbing at it and driving it out of its territory. At 1310 h, an adult osprey circled the pond; it passed over the frogs at between 10 and 15 m height. At this, the frogs immediately became silent and disappeared under cover. No amount of calling by me (normally a successful technique at this pond) could coax them to emerge or continue. The osprey, meanwhile, had landed ca. 15 m up in a fir tree overlooking the pond; it remained there, almost motionless. At 1317 h, after seven minutes of silence, the osprey leapt from its perch, flapped up into the air, and made a swift glide toward the far end of the pond. Stooping low over the water, it snatched a (ca. 150 mm SVL) *R. catesbeiana* from the surface with its talons, circled the pond once (with the frog), then flew away.

Besides the identity of the prey, an interesting aspect of this observation is the fact that the osprey made a long swoop at the prey. Typically, when capturing fish (Rainbow Trout, *Oncorhynchus mykiss*; Black Crappie, *Pomoxis nigromaculatus*; and Bluegill, *Lepomis macrochirus*) in this and adjacent ponds, ospreys hover over the target and make a swift, often vertical dive. Additional observations of osprey capturing frogs may reveal whether different capture methods are used for fish versus amphibian prey.

Submitted by **CHRISTOPHER J. ROMBOUGH**, 2545 Columbia Blvd., Apt. #64, St. Helens, Oregon, 97051, USA (e-mail: rambo2718@yahoo.com).

RANA DRAYTONII (California Red-legged Frog). **DISPERSAL.** Very little information is available regarding dispersal of post-metamorphic juvenile *R. draytonii* from perennial ponds, although mass emigration in response to receding water has been documented for other pond-breeding anurans (Paton et al. 2000. Northwest. Nat. 7[3]:255–269, Pilliod et al. 2002. Can. J. Zool. 80[11]:1849–1862). During the 2003–04 and 2004–05 rain seasons, we captured *R. draytonii* incidentally in pitfall traps while conducting studies for *Ambystoma californiense* at five perennial ponds on the ca. 8094 ha Santa Lucia Preserve near Carmel, Monterey County, California, USA. The study area consisted primarily of a mosaic of grassland, coastal scrub, oak woodland, and redwood forest habitats in four watersheds (Potrero, Robinson Canyon, Las Garzas, San Clemente) that drain into the Carmel River and Pacific Ocean. The property was historically used to graze cattle, and the manmade stock ponds, which ranged in size from 0.08–0.53 ha, were situated in relatively open areas in or near grassland or oak savanna. The purpose of this note is to document mass dispersal of *R. draytonii* metamorphs from perennial ponds, which has conservation and land management implications given that the species is listed as Threatened by the federal government.

We initiated drift fence studies on 15 Oct in 2003 and 2004, prior to the first significant rain each season, and completed them by 1 April. Every pond was partially enclosed with 20 m lengths of 0.914 m high silt fence (Enge 1997. Herpetol. Rev. 28:30–31) buried at least 15 cm and situated 2–10 m from the high water line. Two to 10 m gaps were left between lengths of drift fence to allow free movement of amphibians on nights when the pitfall traps were shut. Each of the five study ponds were ≥ 65% enclosed by drift fence spaced equidistant around the entire perimeter. Paired pitfall

traps (7.6 L) were installed 10 m apart at the ends and middle of each length of fence and covered with an elevated plywood shade. On evenings when rain was forecast (>50% likelihood), traps were opened and checked on the following morning; after each rain event traps were left open for one additional night. We recorded length measurements snout–urostyle length (SUL) from a subset of captured *R. draytonii* and released them in the nearest dense, moist vegetation on the opposite side of the drift fence (outward-bound) or at the edge of the pond (inward-bound).

Pitfall traps were open 57 nights in 2003-04 and 49 nights in the 2004–05 winter seasons. We recorded 308 captures of *R. draytonii* in both years combined, of which 220 were metamorphs (73%). Metamorphs were captured at all ponds although the number varied considerably by location (Table 1). Average size (SUL) of dispersing metamorphs was 30.7 mm (range 22–42 mm; N = 213). The actual number of metamorphs, sub-adults (ca. 45–75 mm) and adults (>75 mm) recaptured was unknown because individuals were not marked. Since there were gaps in the drift fence arrays, any metamorphs captured in outside traps at the end of a drift fence section were still considered to be dispersers; those captured in interior outside traps (N = 15) were excluded from analysis. Therefore, 93% of captured metamorphs were assumed to be dispersers. Given that no inward-bound individuals captured from Dec through March measured < 57 mm SUL (N = 32), there was no indication that any metamorphs returned to the ponds.

In 2003–2004, 95% of all metamorphs were captured by 25 Dec (Fig. 1). Only three metamorphs were captured after 1 Jan, in spite of heavy rains from Jan through March. In 2004–05, 95% of metamorphs were captured by 12 Nov. Similar to the previous year, despite frequent rain from Jan through March, no metamorphs were captured after 30 Dec. In both years, the highest capture frequency occurred during the first significant precipitation of the rain season, even though the magnitude of these events differed markedly (8 mm on 1 Nov 2003 vs. 24 mm on 17 Oct 2004). Precipitation during 2003-04 was 88% of normal while precipitation in 2004-05 was 143% of normal for Carmel Valley, California. These results suggest that the first rains of late summer/early fall, regardless of magnitude, incite dispersal and that most *R. draytonii* metamorphs have left by the end of the calendar year.

The number of captured metamorphs varied considerably between seemingly productive *R. draytonii* breeding ponds. Comparisons of relative abundance to estimate potential recruitment should be viewed with caution, since this study did not target *R. draytonii*. Furthermore, over-wintering *R. draytonii* tadpoles (Fellers et al. 2001. Herpetol. Rev. 32:156–157) were observed at two of the five ponds, and individuals may therefore transform and disperse

TABLE 1. Number of *Rana draytonii* captured in 2003–04 and 2004–05 on the Santa Lucia Preserve, Carmel, California, USA.

Pond #	Season	Metamorphs	Subadults	Adults	Total
2	2003-04	31	0	4	35
3	2004-05	16	2	38	56
13	2003-04	27	1	5	33
17	2004-05	42	12	11	65
27	2004-05	110	0	9	119

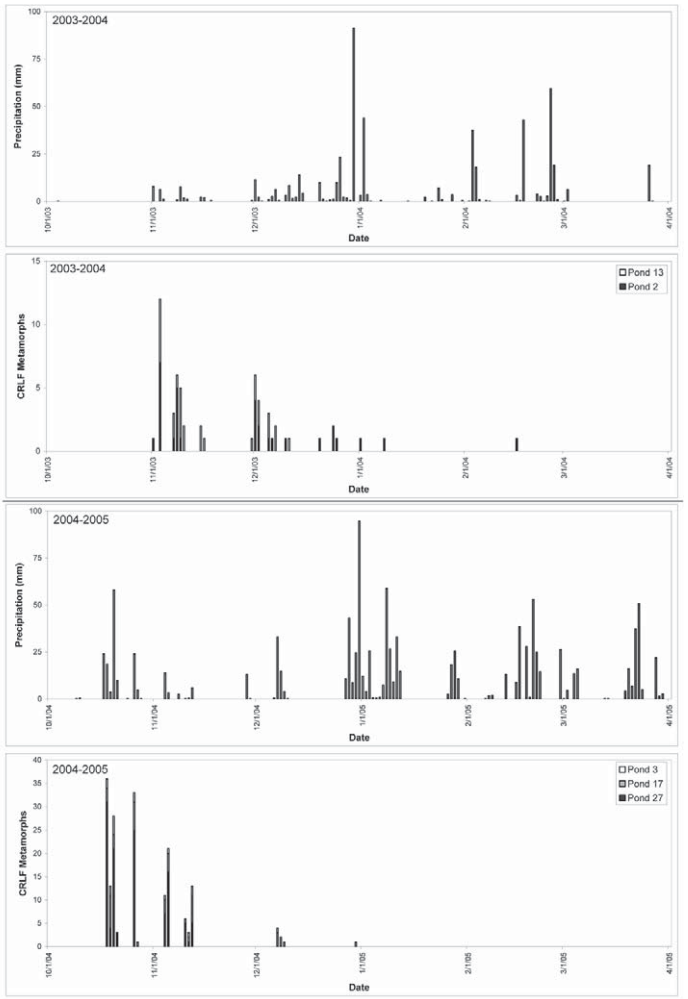

FIG. 1. Precipitation and number of *R. draytonii* metamorphs captured in 2003–04 and 2004–05, Santa Lucia Preserve, Carmel Valley, California, USA.

at nearly anytime of the year when environmental conditions are appropriate. Nevertheless, our data indicates that the first several precipitation events of the fall season incite mass dispersal of *R. draytonii* metamorphs, even at perennial ponds that may appear to provide the appropriate habitat requirements for all age classes. In addition to avoiding predators (including conspecifics), metamorphs presumably disperse to seek appropriate non-breeding habitat until they reach reproductive age and either return or colonize new locations. Our data supports the contention that core-habitat conservation models, which are often symmetrical, may be insufficient for *R. draytonii* and other pool-breeding amphibians that require appropriate movement corridors to ensure connectivity between breeding and non-breeding habitat across a varied landscape (Baldwin et al. 2006. J. Herpetol. 40:442–453; Fellers and Kleeman 2007. J. Herpetol. 41:276–286).

This work was conducted under the authority of U. S. Fish and Wildlife Service Endangered Species Recovery Permits and California Department of Fish and Game scientific collecting permits. The Western Regional Climate Center (Reno, Nevada) provided precipitation data from the Carmel Valley station (#041534). We are grateful to the Santa Lucia Preserve for access to the ponds and assistance with installation of the drift fences, and to the Rancho San Carlos Partnership for partial funding of this study.

RANA DRAYTONII (California Red-legged Frog). **PREY.** Although ranid frogs generally have indiscriminant diets, data regarding vertebrate food items taken by *Rana draytonii* are sparse. Vertebrates documented as prey include *Gasterosteus aculeatus* (Three-spined Stickleback), *Pseudacris regilla* (Pacific Chorus Frog), *Peromyscus californicus* (California Mouse) (Hayes and Tennant 1985. Southwest. Nat. 30:601–605), *Microtus californicus* (California Vole), and *Reithrodontomys megalotis* (Western Harvest Mouse) (Hayes et al. 2006. Herpetol. Rev. 37:449). Although expected, snakes have not been reported as dietary items.

On 13 Aug 2008, at 0030 h, while conducting surveys for *R. draytonii* at a pond in the Sierra Nevada foothills in northern California (Placer Co.), an adult frog (ca. 100 mm) was observed grabbing and quickly devouring a juvenile (ca. 20 cm SVL) *Thamnophis sirtalis* (Common Gartersnake). The *T. sirtalis* had been slowly moving across a flat, muddy bank covered with *Eleocharis* sp., and the *R. draytonii* was situated at the water/mud bank margin, quiescent, facing into ponded open water. Consistent with other feeding observations of ranid frogs (Anderson 1993. J. Exp. Biol. 179:1–12), the *R. draytonii*, upon lunging and grabbing the snake, used its forelimbs to manipulate the snake farther into its mouth. The capture and swallowing of the snake occurred within a period of five to seven seconds and the snake was entirely engulfed within that time. The temperature at the time of observation was 23°C, water temperature was 23.5°C, humidity was ca. 50%, and moon phase was waxing, approaching full.

RANA PIPIENS (Northern Leopard Frog). **WINTER ACTIVITY**. On 10 Dec 2006 at ca. 1200 h, a *Rana pipiens* was observed on the north shore of Lake Winter located in Northern Wisconsin (45.8°N, 91.1°W). The lake was covered with approximately 2–3 inches of ice, except the occasional narrow opening near the shore. The south-facing shoreline was somewhat undercut from erosion and about 30.5 cm of soil was exposed. While walking out onto the ice from the shoreline a *R. pipens* was observed jumping away from shore and out onto the ice and snow. The *R. pipens* appeared to be rather torpid and its skin appeared rather dry and leathery.

The previous weather was cold, often with maximum temperatures well below the average maximum temperature for those days. On 9 Dec 2006 the temperature increased to a maximum of 1.7°C and then continued to climb to around 4–5°C during the day of the observation, which was mostly sunny. 5.6°C was the maximum temperature that day; two degrees below the 6.7°C record set in 2002 and well above the typical average maximum temperature of -1.6°C (temperature data accessed on-line from www.undergroundweather.com).

RANA SYLVATICA (Wood Frog). **EGG MASS SURVEYS.** Egg mass counts have become an increasingly popular method for estimating reproductive effort of Wood Frogs in seasonal breeding pools in the northeastern United States. Scientists, conservation organizations, and regulatory agencies use egg mass counts to determine population size and track population trends over time, to identify breeding pools in need of protective measures, and to develop indices based upon biological significance (Couch and Paton 2000. Wildl. Soc. Bull. 28[4]:895–901; Oscarson and Calhoun 2007. Wetlands 27[1]:80–95). Wood Frog ovipositioning typically occurs in communal rafts attached to submerged vegetation at or near the water surface (Couch and Paton, *op. cit.*; Egan and Paton 2004. Wetlands 24(1):1–13; Seale 1982. Copeia 1982[3]:627–635). In many northeastern states, citizen scientists are being trained to assess the ecological value of vernal pools through egg mass counts. Using snorkel equipment for one such survey in Maine, I found that the subsurface view of a large raft of Wood Frog egg masses revealed numerous masses on the pool bottom. Between 0.5 and 1 m below the communal aggregation of egg masses attached to *Ilex verticillata* at the water surface, some masses were clearly attached to submerged vegetation at the pool bottom while others were merely resting on a substrate of leaf litter. During 2009 springtime assessments (27 April–5 May), three pools (Penobscot County, Maine, USA; 44.884°N, 68.688°E; NAD 1983) were found to contain Wood Frog egg masses directly below and around the margins of rafts attached to vegetation near the water surface. There was no lack of attachment sites near the water surface in any of the three pools. Whether they were originally deposited in situ or were secondarily dislodged and came to rest on the pool bottom is unknown. In deep or tannic pools where visibility is poor, egg mass counts may have the potential to underestimate the true number of masses that occur within a pool.

RHINELLA ARENARUM (Common Toad). **MORTALITY**. Car traffic often results in high amphibian casualties when roads are encountered during breeding or other movements. *Rhinella arenarum* is the common toad in Argentina (Cei 1980. Amphibians of Argetina. Monitore Zoologico Italiano [NS]. Monogr. 2, 609 pp.). In San Juan Province this species is distributed in all wetted areas including the watering systems of towns. On 23 Nov 2008, we counted the toads dead on the streets in Valle Fértil Departament. This region belongs to the Chaco Seco Phitogeografical Province (Cabrera 1994. Enciclopedia Argentina de agricultura y ganadería. Editorial ACME S.A.C.I., 81 pp.). During this time 84 dead toads were encountered on the road in 900 m. All toads were 89 ± 18.8 mm, typical of adult reproductive *R. arenarum*. This is

the first report of the extent of toad mortality on the roads of San Juan Province, Argentina.

We thank L. Quiroga for review of this note.

SCAPHIOPUS HOLBROOKII (Eastern Spadefoot). **PREDATION**. *Scaphiopus holbrookii* is an aquatic breeding terrestrial amphibian which, with exception to several days in any year when the species may breed, is predominantly nocturnal in its habits; diurnal hours are spent underground in burrows (Pearson 1955. Ecol. Monogr. 25:233–267). This activity pattern is believed primarily to be an adaptation to avoid desiccation (Bragg 1961. Anim. Behav. 9:178–186), though may also act to reduce predation risk.

Known predators of *S. holbrookii* include various species of mammals, snakes, and birds, though we are not aware of any reports of raptor predation on *S. holbrookii*. During a pilot radiotelemetry investigation of adult *S. holbrookii* movement patterns at Cape Cod National Seashore in Provincetown, Massachusetts (USA), we observed indirect evidence of owl predation on an adult *S.. holbrookii*. Specifically, during 25 August 2005 we found a radio-transmitter from an adult male *S. holbrookii* (SVL 5.4 cm, mass: 19.25 g) inside a small owl pellet on the ground surface. While we were unable to identify the owl species the pellet was from, there are only three species of owl known to inhabit the study area during the late-August time period including: Great Horned Owl (*Bubo virginianus*), Barred Owl (*Strix varia*), and Northern Saw-whet Owl (*Aegolius acadicus*).

SCINAX LITTORALIS (Snouted Treefrog). **PREDATION**. Amphibians and reptiles are commonly preyed upon by spiders (Neill 1948. Herpetologica 4:158). In the Atlantic Forest, the spider *Ancylometes* spp. (Araneae, Ctenidae) has been reported as an anuran predator (Bernarde et al. 1999. Biociências 7:199-203; Serafim et al. 2007. Herpetol. Rev. 38:437; Haddad et al. 2008. Atlantic Forest Amphibians: Guide for the Atlantic Forest Anurans. Editora Neotropica, São Paulo. 244 pp.). Herein, we report predation of an adult *Scinax littoralis* in Ubatuba, São Paulo, southeastern Brazil (23º30'02.4''S, 45º05'01.4''W, 40 m elev.). On 21 Sept 2008 at 2000 h, one of us (PJPC) observed an adult male *Scinax littoralis* (27.3 mm SVL) that was being consumed by the spider *Ctenus medius* (Araneae, Ctenidae) (46 mm SVL) (Fig.1).

This frog was collected and deposited in the Coleção Jorge Jim, UNESP, Botucatu, SP. We thank A.D. Brescovit for identification of the spider.

SMILISCA BAUDINII (Mexican Treefrog). **DIET.** *Smilisca baudinii* is a moderate to large (55–65 mm SVL) nocturnal treefrog (Savage 2002. The Amphibian and Reptiles of Costa Rica: A Herpetofauna Between Two Continents, Between Two Seas. University of Chicago Press, Chicago, Illinois. 934 pp.). Mexican Treefrogs are known invertivores feeding mostly on insects and spiders (Lee 2000. A Field Guide to the Amphibians and Reptiles of the Maya World: The Lowlands of Mexico, Northern Guatemala, and Belize. Cornell University Press, Ithaca, New York), with grasshoppers reported in the stomachs of specimens collected from Nicaragua (Noble 1918. Bull. Amer. Mus. Nat. Hist. 38[10]:311–347). Here we report the first vertebrate prey item for *S. baudinii*.

At 1015 h on 7 Jan 2007 we located a female *S. baudinii* (6.0 cm SVL, 13.0 g) ca. 2.0 m high on the trunk of an oak tree (*Quercus oleoides*) in Cayo Cochino Pequeño, Cayos Cochinos Archipelago, Islas de la Bahia, Honduras. The frog contained a large food item in its gut and appeared to have a lizard tail protruding from its mouth. After capturing the frog and forcing it to regurgitate the prey item, we identified the partially digested lizard as an adult male (6.5 cm SVL, 12 cm tail, 5.0 g) *Norops lemurinus*. The lizard represented a 38.5% meal by mass and a 108.3% prey item by SVL length. Our observation represents the first report of *N. lemurinus* in the diet of *S. baudinii*, as well as the largest reported meal by mass or length for *S. baudinii*.

We thank the Honduran Coral Reef Foundation and Operation Wallacea for supporting our research in the Cayos Cochinos.

SMILISCABAUDINII (Mexican Treefrog) and ***PACHYMEDUSA DACNICOLOR*** (Mexican Leaf Frog). **REPRODUCTION**. Interspecific mating interactions are known to occur when the reproductive activities of amphibian species overlap temporally and spatially (Höbel 2005. Herpetol. Rev. 36:55–56; Höbel 2005. Herpetol. Rev. 36:439–440; Waterstrat et al. 2008. Herpetol. Rev. 39:458). In some cases, it has been suggested that these encounters may act as reproductive interference leading to negative demographic consequence (Pearl et al. 2005. Am. Midl. Nat. 154:126–134). Herein we report an instance of interspecific amplexus between two hylid species. On 11 June 2008 at ca. 0100 h near the city of Uruapan, Michoacán, México (19.24277°N, 102.05228°W, 931 m elev.) we encountered an extremely large (>1500 individuals) multiple-species breeding chorus of anurans. The chorus included five species: *Pachymedusa dacnicolor*, *Leptodactlyus melanonotus*, *Tlalocohyla smithii*, *Rhinella marina*, and *Smilisca baudinii*. The most frequently encountered species were *P. dacnicolor* and *S. baudinii*. Amidst this majestic euphony we located an amplectant pair consisting of a male *S. baudinii* and a female *P. dacnicolor* (Fig. 1). Although cross-species amplectant behavior has frequently been reported among anurans and can be inferred for a number of temperate hylid species known to hybridize (e.g., Lamb et al. 1990. J. Evol. Biol. 3:295–309), there are few published reports of mating errors in tropical hylids or of amplectant interaction between hylid subfamilies.

FIG. 1. Male *Smilisca baudinii* in amplexus with female *Pachymedusa dacnicolor*, found during large multi-species breeding chorus in western Michoacán, México (UTADC 4000).

We thank J. A. Campbell for assistance. Identifications were verified by E. N. Smith. A photographic voucher of this pairing was deposited in the University of Texas at Arlington Digital Collection (UTADC 4000).The National Science Foundation (DEB-0613802 to J. A. Campbell) provided financial support.

WEATHERMAN**, Golondrinas 94, Campo Verde, Puerto Vallarta, Jalisco, México 48290.

SMILISCA PHAEOTA (Masked Tree Frog). **UNILATERAL MYDRIASIS**. Excessive dilation of the pupil is known as mydriasis. In anurans, fixed mydriasis has been reported during local population declines in conjunction with the presence of the fungal pathogen *Batrachochytrium dendrobatidis* (Hale et al. 2005. USDA Forest Service Proc. 36:407–411). The condition of unilateral mydriasis (excessive dilation of a single pupil) in frogs, defined as an abnormality by the U.S. Fish and Wildlife Service (USFWS Abnormality Classification SOP website via http://www.fws.gov), is rarely reported outside of North America and Europe. Here we report the in situ occurrence of fixed unilateral mydriasis in a tropical hylid species. On 16 March 2008 we made a small collection of anurans near the town of San Lorenzo in Esmeraldas, Ecuador (1.26219°N, 78.79528°W, 40 m elev.). Part of the collection was an adult *Smilisca phaeota* (48.5 mm SVL) that possessed an uneven dilation of its pupils (Fig. 1A). When exposed to daylight, the right pupil of the specimen (Fig. 1B) was excessively dilated whereas the left pupil (Fig. 1C) appeared to respond normally. Most unilateral ophthalmic abnormalities documented in frogs are suggestive of

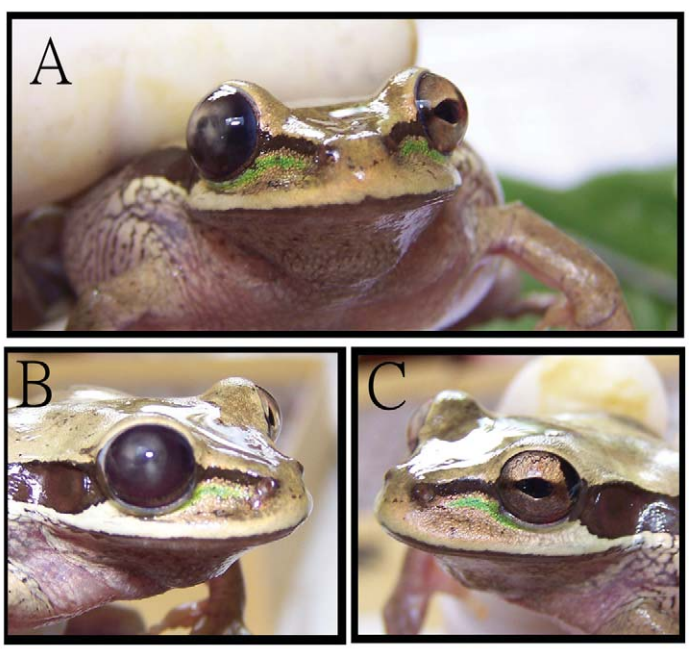

FIG. 1. Unilateral mydriasis in a *Smilisca phaeota* (UTA A-58905) from western Esmeraldas, Ecuador.

trauma or focal disease (Ballard and Cheek 2003. Exotic Animal Medicine for the Veterinary Technician. Blackwell Publishing. 379 pp). Stimulation or damage of sensory nerves is known to cause pupil dilation (Klopper 1951. Acta. Physiol. Pharmacol. Neerl. 2:8–13) as are subcutaneous drug injections and direct exposure to certain chemicals (Meltzer and Auer 1904. Am. J. Physiol. 11:449–454; Wright and Whitaker 2001. Amphibian Medicine and Captive Husbandry. Krieger Publishing, Malabar, Florida. 449 pp.). Based on examination in the field and a subsequent assessment of the preserved animal, there are no obvious external injuries to the specimen. However, it remains unclear whether the condition reported herein resulted from traumatic injury or an association with disease. Additionally, tropical hylids possessing ocular anomalies have been reported to survive in the wild for at least short periods of time (Carvaho et al. 2008. Herpetol. Rev. 39:211), so it is difficult to assess if this case of mydriasis was of relatively recent origin or a longer held affliction.

The specimen was deposited in the herpetological collection of the University of Texas at Arlington (UTA A-58905, Field ID: ENS 12598) and was collected under permit N 001-08 IC-FAU-DN-BAPVS/MA. In vivo images of the frog were deposited in the UTA Digital Collection (UTADC 3718–3720). Financial support was provided to ENS by the Instituto Bioclon (Mexico), UTA (start-up funds), and the National Science Foundation (DEB-0416160).

SPEA MULTIPLICATA (Mexican Spadefoot). **PREDATION.** The fact that spiders prey on anurans is well documented. Much of the literature on the subject was reviewed and summarized by McCormick and Polis (1982. Biol. Rev. 57:29–58) and Toledo (2005. Herpetol. Rev. 36:395–400) and subsequent to the latter, multiple new accounts have appeared in every volume of this journal. Considering the diversity of the two orders however, the extent of published examples specifically identifying the species involved is relatively limited. Toledo (2005, *op. cit.*) recorded 68 post-metamorphic species of anuran preyed upon by 30 species of Araneae documented in the literature. This amounts to only 1.2% of the 5602 anuran species currently listed by Frost (2008. Amphibian Species of the World: an Online Reference. Version 5.2 (15 July 2008). http://research.amnh.org/herpetology/amphibian/index.php) and 0.07% of the 40,462 Araneae species listed by Platnick (2008. The World of Spider Catalog, ver. 9.0 http://research.amnh.org/entomology/spiders/catalog/index.htm/). Jackman et al. (1983. Science 222:515–516) recorded the larvae of the fly *Tabanus punctifer* preying on recently metamorphosed *S. multiplicata*. Pomeroy (1981. Ph.D. thesis. Univ. California, Riverside. *fide* McCormick and Polis 1982, *op. cit.*) identified the nymphs of dragonflies (Odonata), backswimmers (*Notonecta undulata*), dung beetles (Scarabaeidae), and larvae of diving beetles (*Thermonectes* sp.) as predators of *S. multiplicata* tadpoles, and a tiger beetle (*Cicindela sedecimpunctata*) as predators of adults.

This appears to be the first record of an Araneae, in this instance an unidentified tarantula (Theraphosidae), preying on *S. multiplicata*, although Toledo (2005, *op. cit.*) included eight examples of Theraphosidae preying on other species of frogs. The observation occurred at 1819 h on 14 Oct 2006 in the state of Tamaulipas, Mexico, in the municipality of Miquihuana, 1 km SW of the remote village of Aserradero, located on a dirt road 12.5 km. N of the town of Miquihuana (WGS84, 23.6791667°N, 99.7563889°W; 2473 m elev), Temperature was 21°C; barometric pressure 31.33. The habitat at this locality in the Sierra Madre Oriental is pine-oak forest with madrone (*Arbutus xalapensis*) and agaves (*Maguey americana* and *M. asperrima*). It is generally a semiarid environment with surface water limited to a few arroyos and washes that seldom support more than a few isolated shallow pools although afternoon rains occur almost daily throughout the summer. A few distantly located cattle tanks and seasonally active seeps are present in the region. In the immediate area where the observation took place, ca. 2 or 3 hectares had been cleared of the smaller trees and undergrowth, presumably for livestock grazing, leaving only some of the larger trees in a pasture with occasional bunchgrass and an abundance of fallen logs. An arroyo delineates the north side of the pasture.

The event was observed while turning over rocks in the pasture. The initial attack was not witnessed. The tarantula was first seen holding the *S. multiplicata* after a moderately large stone was turned. We observed the spider, which remained motionless for ca. 2–3 minutes, seemingly disturbed from feeding by the rock having been moved. When attempts were made to take photographs, the spider dropped the toad and retreated ca. 10–20 cm and did not return to its prey. The *S. multiplicata* was alive but appeared to be paralyzed, presumably from the effect of the spider's venom. The toad was whole, intact, with no obvious wounds or necroses, suggesting that it had only very recently been caught and the spider had not begun consuming its prey. The elytra and some other body parts from a Beetle (Tenebrionidae), presumably preyed on earlier by the same spider, where found in a small tunnel excavated under the rock, the rock its self providing the ceiling of the chamber before it was turned over. Toledo (2005, *op. cit.*) reported that almost 90% of recorded instances of invertebrates preying on post-metamorphic anurans take place in or at the water's edge, when either recently metamorphosed frogs are leaving the water, or when adults congregate and enter the water for breeding, all circumstances which are not applicable to this case. The *S. multiplicata*, a small adult (2.4 cm SVL; 1.25 g), was weighted and measured in the field before being preserved. It was deposited in the collection of the Universidad Autónoma de Nuevo Leon, UANL 6500 along with a second specimen UANL 6501, measuring 2.6 cm. found under a nearby rock. The spider was left in the field where found. Fieldwork was conducted under SEMARNAT permit no. 00800/06 and funded by HZI.

STEREOCYCLOPS INCRASSATUS (Brazilian Dumpy Frog). **DEFENSIVE BEHAVIOR.** *Stereocyclops incrassatus* is a Brazilian microhylid, found in humid coastal forests in eastern Brazil from Espírito Santo to Bahia (Frost 2009. Amphibian Species of the World: an Online Reference. Version 5.3; http://research.amnh.org/herpetology/amphibia/. American Museum of Natural History, New York). Ecological or behavioral information for this genus is scarce, but includes a description of feeding habits in *S. incrassatus* (Teixeira et al. 2006. Bol. Mus. Biol. Mello Leitão 19:53–58) and a description of defensive behavior in *S. parkeri* (Sazima 1978. Biotropica 10:158). Herein, we describe an unreported defensive behavior for *S. incrassatus*.

At ca. 1700 h on 12 March 2009, we observed the defensive behavior of an adult male *S. incrassatus* (44 mm SVL) against a predation attempt by an adult colubrid snake, *Liophis milliaris merremi* (559 mm SVL. 127 mm TL). The animals were found in the vicinity of the municipality of Itacaré, Bahia state, Brazil (WGS84, 14.2888128°S, 38.984219°W; elev. ca. 10 m). The snake was trying to swallow the frog headfirst. With the head already inside of snake's mouth, the frog was displaying the following defensive position: the head was pressed against the ground, the back was raised, the body inflated, and the fore and hind limbs were strongly retracted against the body, giving the frog a solid and round shape. When we approached, the snake regurgitated the frog and we noticed that its mouth and a small part of the frog's body was covered by a glue-like secretion produced by the frog. The secretion was visibly sticky, as it adhered sand grains to both animals. It was not apparently whitish, but the adhered sand might influence our perception of the color of the secretion. The secretion made it difficult for the snake to open its mouth for approximately a minute. After several unsuccessful attempts, the snake was finally able to open its mouth by itself. During that time, the frog remained in the position described above until, in the hands of one of us, it flattened its body and stretched out its four limbs. When placed on the ground it raised its head and remained in this flattened position for more than a minute (Fig. 1).

This is the first description of defensive behavior for *S. incrassatus*. This is the first time that a defensive posture with all the limbs pressed against the body and the head pressed against the ground has been reported for a Brazilian microhylid. Flattening the body and stretching all the limbs at the same time has also not been previously described for any Brazilian microhylid. We did not see any color in the *S. incrassatus* secretion. Secretion of sticky substances is a useful defensive tactic, as it causes almost immediate liberation of the prey (Evans and Brodie. 1994. J. Herpetol. 28:499–502). All these data support the idea that many anurans may combine secretions with different body positions to increase defense success.

FIG. 1. Posture maintained by a *Stereocyclops incrassatus* after being handled by one of the observers.

The specimens are deposited in the herpetological collection of the Museu de Zoologia da Universidade de São Paulo (MZUSP), São Paulo, Brazil (*Liophis miliaris merremi*, MZUSP 17732, and *S. incrassatus*, MZUSP 141343). We thank IBAMA for collection permits (14555-1).

CROCODYLIA — CROCODILIANS

CROCODYLUS ACUTUS (American Crocodile). **NESTING ECOLOGY.** *Crocodylus acutus* is widely distributed in the Atlantic and Pacific coasts of Mexico, Central America, and northern South America, many Caribbean islands, and southern Florida (Ernst et al. 1999. Cat. Amer. Amph. Rept. 700:1–17). Information on nesting ecology has been documented in Caribbean atolls and coast habitat (Ogden 1978. J. Herpetol. 12:183–196; Platt and Thorbjarnarson 2000. Copeia 2000:869–873; Casas-Andreu 2003. Acta Zool. Mex. [n.s.] 89:111–128; Mazzotti et al. 2007. Herpetol. Rev. 38:285–289; Charruau et al. 2010. J. Nat. Hist., *in press*). However, there is a paucity of information on nesting ecology of *C. acutus* in mainland and man-made habitat. Hence, here we present observations on its nesting ecology in El Cajon Reservoir in central Honduras.

We searched for nests around the main rivers and secondary tributaries of El Cajon Reservoir (15.01078ºN, 87.71149ºW, datum: WGS84, elev. 285 m) in February–April 2005. We found 30 nests of *C. acutus*: two on the Yure River, 16 on the Humuya River, and 12 on the Sulaco River. Nest holes were constructed by *C. acutus* that were found in the shoreline vegetation and elevated areas away from shoreline and creeks. The nest areas were characterized by very steep slopes and the presence of sandy and rocky soil.

We observed hatchlings at each nest site during May and June. The number of hatchlings varied from 10 to 21 per nest on the Yure River, 10 to 27 on the Humuya River, and 10 to 33 on the Sulaco River. Successful nests were determined by the presence of eggshell membranes indicating the nests were excavated by the nesting female. Platt and Thorbjarnarson (2000, *op. cit.*) observed that females defend nests from predators but parental care was minimal or non-active. In El Cajon Reservoir, we observed active parental care during our surveys.

We thank Programa Multifase de Manejo de Recursos Naturales en Cuencas Prioritarias-MARENA who provided financial and equipment support. We wish to acknowledge Roney Buezo, manager of Grupo Facilitador Humuya Medio, and José Francisco

RYNCHOCEPHALIA — TUATARA

SPHENODON PUNCTATUS (Tuatara). **FRUGIVORY.** The unique assemblage of plants and limited animal species in New Zealand, as on many isolated islands, has allowed novel seed dispersal relationships to evolve (Valido and Olesen 2007. *In* Dennis et al. [eds.], Seed Dispersal: Theory and its Application in a Changing World, pp. 124–147. CAB International, Wallingford). Seed dispersal is essential for gene flow and maintaining ecological structure in plant communities. Our understanding of these systems and their dispersal vectors are vital for the conservation of native ecosystems with nearly 70% of woody species in New Zealand possessing fruit suitable for vertebrate seed dispersal (Clout and Hay 1989. New Zealand J. Ecol. 12:27–33). Some New Zealand plants exhibit growth forms that are thought to be conducive to lizard-mediated seed dispersal (Lord and Marshall 2001. New Zealand J. Bot. 39:567–576). Twelve species of frugivorous lizards in New Zealand have been identified as potential seed dispersers (Whitaker 1987. New Zealand J. Bot. 25:315–328). New Zealand's largest lepidosaurian, *Sphenodon punctatus*, has been characterized as a generalized opportunistic carnivore that subsists primarily on beetles, insect larvae, arachnids, and weta (Ussher 1999. New Zealand J. Zool. 26:117–125; Walls 1981. New Zealand J. Ecol. 4:89–97). Seeds in tuatara scat and stomach contents (Ussher 1999, *op. cit.*; Walls 1981, *op. cit.*; Southey, cited in Whitaker 1987, *op. cit.*) have been dismissed as instances of reptile frugivory and seed dispersal because they were thought to be indirectly or accidentally consumed (Valido and Olesen 2007, *op. cit.*). Here we provide the first evidence for intentional frugivory by the tuatara and report on its implications for effective seed dispersal.

During fieldwork on Stephens Island (40.67°S, 174.00°E) in March 2009, two *Sphenodon punctatus* scat samples were discovered that contained a large number of seeds. The first sample (Sample 1) was freshly deposited on 11 March inside the collection bag of an adult male tuatara (SVL = 230 mm, mass = 370 g) and the second sample (Sample 2) was discovered on 23 March deposited by an unknown tuatara on a concrete pathway roughly 75 meters from Sample 1. The distance between these samples make it unlikely to be the same individual, as this species is highly territorial (Moore et al. 2009. J. Herpetol. 43:570–578).

Dissection of Sample 1 and Sample 2, revealed a few arthropod body fragments, identified as common small beetle species with the majority of the sample being comprised of seeds and several stems. Comparison with collected seed samples identified the seeds as Kawakawa (*Macropiper excelsum*), and thorough counts yielded at least 407 intact seeds in Sample 1 and 1343 intact seeds and 41 seed fragments in Sample 2. Seed fragments were considered any seed that had sustained damage that exposed the endosperm. Kawakawa is a common understory shrub in the regenerated and degraded original forest patches on Stephens Island (Mulder and Keall 2001. Oecologia 127:350–360), and was fruiting in abundance in March 2009. Kawakawa possess bright orange, aromatic, aggregate fruit spikes which can contain up to 150 seeds per spike (Burrows 1995. New Zeal J Bot**.** 33:131–140). When Sample 1 was collected it had a distinct orange-tinge aiding in the plant's identification. Comparison with fresh fruit spikes shows that the stems found in the fecal samples were the central stems of the aggregate fruit with three and nine stems found in Sample 1 and Sample 2, respectively. The fruit spikes can fall intact to the ground when the plant is agitated and fruit are ripe (K. C. Burns, pers. comm.) making them available to terrestrial animals. The presence of the fruit spike stems in the scat samples provides evidence for direct consumption of several whole fruit spikes since other frugivores (e.g., geckos and Weta) with smaller mouths remove the fruit flesh from the central stem (pers. obs.). In order to ingest the large number of seeds found in each sample, the number of whole fruit spikes that would need to be consumed is at least two and nine, respectively, for Sample 1 and Sample 2. The absence of large prey remains, the presence of fruit spike stems and the large number of seeds all suggest the direct consumptions of fruit spikes by tuatara.

To examine the viability of these seeds, germination trials were performed on two subsets of seeds that were deemed intact under 10× magnification from fecal Sample 1 (N = 53, 50) and Sample 2 (N = 65, 50), along with two sets of controls comprising defleshed seeds from ripe Kawakawa fruit spikes (N = 66, 50). Once removed from the island, seeds were stored in plastic petri dishes in a cool refrigerator. For the trials, seeds were placed in glass Petri dishes with a saturated filter paper substrate and placed under 12-h light: dark timer controlled fluorescent grow lights. The first sets were started on 16 April 2009 with the second sets beginning on 30 June 2009. Seeds were checked weekly over the following seven weeks by performing counts of radicle and cotyledon emergence. The control, Sample 1, and Sample 2 average percent emergence rates of radicle (93.2%, 79.1%, 99.1%, respectively) and cotyledon (49.5%, 31.3%, 43.1%, respectively) were roughly similar between samples. Critically, this indicates that many seeds passed by the tuatara are still viable.

Excretion of viable seeds provides the possibility of seed dispersal by tuatara regardless of the method of consumption or germination rate. Other examples of seed dispersal by traditionally carnivorous animals have been documented in recent years (Calviño-Cancela et al. 2007. Écoscience 14: 529–534; Otani 2002. Ecol Res. 17:29–38). It has even been suggested that a carnivore's dentition lend them to be more effective seed dispersers than herbivores because they cause less damage to seeds during mastication (Otani 2002, *op. cit.*). Tuatara should not be disregarded as a potential seed dispersal vector because of their primary diet.

A whole suite of potential questions raised by this observation can be divided into two general groups. The first group is those questions about the biology of tuatara: How frequent is this behavior? What implication does this have for the diet of tuatara? With the dense population of tuatara on Stephens Island (Moore et al. 2007. Biol Conserv. 135:181–188), could frugivory be an alternative feeding strategy due to intense resource competition? These fecal samples were found during the mating season of the tuatara; could a high caloric demand be leading to fruit consumption? If tuatara are intentionally eating the Kawakawa fruit, are

they locating them by olfaction, color, or ultraviolet vision? The second group involves questions about the ecological implication for this frugivory: How does the deposition pattern and microhabitat, e.g. clumped or scattered on sunny open soil or down a burrow, of deposited seeds impact germination (Williams et al. 2000. Austral Ecol. 25:523–532; Wotton 2002. New Zealand J. Bot. 40:639–647)? Stephens Island only has a subset of New Zealand plants; could the tuatara's historical range have included access to other fruiting plants they would consume? Does the territorial tuatara move over enough area to effectively disperse seeds? Further research is needed to understand this occurrence of tuatara frugivory and its implications for their diet and seed dispersal in remnant and historical New Zealand ecosystems.

TESTUDINES — TURTLES

ACTINEMYS* (= *EMYS*) *MARMORATA (Western Pond Turtle). **PREDATION**. The Western Pond Turtle is in decline over 80% of its historical range in California, primarily due to habitat loss and competition from introduced species (Stebbins 2003. A Field Guide to Western Reptiles and Amphibians, 3rd ed., Houghton Mifflin, Boston, Massachusetts). Wild pigs *(Sus scrofa)*, hybrids of feral domestic pigs and European wild boars, are a purposely introduced species rapidly increasing in range and population throughout the state (Waithman et al. 1999. J. Wild. Manag. 63[1]: 298–308). Wild pigs are omnivores, and forage for and consume a wide variety of vertebrate prey (Wilcox and Van Vuren 2009. J Mammal. 90[1]:114–118). Worldwide, feral pigs have been documented to consume eggs and young of four chelonian species, including Green Sea Turtles *(Chelonia mydas)*, giant tortoises *(Chelonoidis nigra [=Geochelone elephantopus])* in the Galapagos (Coblentz and Baber 1987. J. Appl. Ecol. 24:103–118), Spur-thighed Tortoises *(Testudo* spp.*)* in Sardinia (Corbett [ed.], 1989. The Conservation of European Reptiles and Amphibians. C. Helms, London), and Texas Tortoises *(Gopherus berlandieri)* (Taylor and Hellgren 1997. Southwest. Nat. 42[1]:33–39). I report below on the first documented case of wild pig predation on the eggs of Western Pond Turtles.

Early on the morning of 21 October 2003, I went to check the progress of a pond-draining project at Cabin Pond (37.37953°N, 121.73146°W) on the Blue Oak Ranch in Santa Clara County, California, USA. In the heat and aridity of the California autumn, the moist basin of the receding pond had attracted wild pigs. Overnight, they had wallowed in the deep mud and thoroughly rooted for earthworms in the moist soil around the shallow end of the pond basin. Three pigs were in the basin when I arrived. Two were rooting beyond where the soil moisture ended in the grass-covered uplands on the slope, ca. 20 m above and beyond the pond. The pigs bolted for cover as soon as they saw me. Moments later, while inspecting the area, I discovered remnants of three turtle eggs in the mounds of soil and dried plant matter where the pigs had rooted. There was a moist, viscous fluid still clinging to the inside of the shells. In the hard earth just below the mound of soil that held the eggs was an elliptical depression about 5 cm across and 3 cm wide. The exact dimensions were difficult to judge due to the rooted conditions.

A number of morphological and behavioral traits make wild pigs ideal predators of turtle nests and eggs. Nest sites of Western Pond Turtles typically are within close proximity of streams and ponds; riparian areas are likewise favored resting and foraging places for wild pigs. Turtle nests typically are no more than 8 cm in depth (Rathbun et al 1992. Southwest. Nat. 37[3]:319–324); wild pigs often root to depths much greater than 8 cm, depending on the soil depth and moisture. Wild pigs' excellent sense of smell may help them detect turtle nests (though they also may encounter turtle eggs in the course of routine rooting). Pigs also have remarkable oral dexterity, which allows them, for example, to detect and swallow earthworms without ingesting soil and may allow them to do the same with small eggs.

In the incident described above, wild pigs were interrupted in the act of predating on turtle eggs—but wild pigs normally swallow their prey whole, leaving no evidence on the ground. The behavior observed serendipitously on the Blue Oak Ranch may therefore happen more often than is witnessed. The spread of wild pigs throughout California could be exacerbating the decline of Western Pond Turtles where these species occur together.

CHELONIA MYDAS (Green Seaturtle). **DISEASES**. Infectious agents such as fungi and bacteria are known pathogens in marine turtles. Derivative of these kinds of diseases, external and internal tumors may be generated and mainly affect immature animals (Herbst 1994. Annu. Rev. Fish. Dis.4:389–425). In *Chelonia mydas*, *Vibrio harveyi* and *Bacillus* sp. have been described as infectious agents (Work et al. 2003. Dis Aquat Org. 53:41–46). Fungi like *Fusarium oxysporum*, *Fusarium solana* and *Pseudallescheria boydii* are found in the eggs of *Chelonia mydas*, *Eretmochelys imbricata*, *Caretta caretta*, and *Natator depressus* and can cause death of embryos (Phillott and Parmenter. 2001. Aust. J. Zool. 49:713–718; Phillott 2004. Herpetologica. 34:44–47). There are reports of *Colletotrichum acutatum* in juvenile *Lepidochelys kempii*, with infection in lungs and kidneys (Manire et al. 2002. J. Clin. Microbiol. 40:4273–4280).

There are apparently no published studies on the incidence of infectious agents in marine turtles and nests in Mexico, even though these agents may be important causes of mortality in embryos and hatchlings. Here we document the presence of fungi and bacteria in nests of *C. mydas* on a beach in Veracruz, Mexico.

We took 26 vitello samples from the beach of the "Centro de Protección y Conservación de Tortugas Marinas" in Santander, Veracruz, Mexico. The eggs tested did not appear damaged or show visible signs of infection. For each nest, we counted living and dead hatchlings. The samples were obtained using sterile cotton applicator and cultured on potato dextrose. The samples were kept at 21°C to 23°C during 72 h of incubation. To identify the differences among the infectious agents we used a Cochran Q test, using a 1-0 matrix.

In the samples of *Chelonia mydas* eggs we found *Candida albicans* fungi in 20 samples, and *Staphylococcus aureus* and *Escherichia coli* bacteria were found in eight and five samples, respectively. Ninety-six per cent of all nests presented with at least one of the three infectious agents, although none of the 26 nests presented with the three agents at the same time.

In nests with *Escherichia coli*, mortality was 100%, even when all the embryos were completely developed. In the nests with *Candida albicans* and *Staphylococcus aureus*, mortality was 15% and 20%, respectively. Some individuals showed malformations, including blindness, absence of anterior flippers, and notable differences in size and weight.

The presence of the infectious agents was similar in all nests ($Q = 12.53$; $P>0.05$), nevertheless, for each agent, significant differences were found ($Q = 15.12$: $P< 0.05$).

The source of bacteria and fungi in the Green Seaturtle nests on Santander beach is unclear. Nest invasion by domestic animals such as dogs and pigs, or the disruption of older nests by later nesting females could be a possible source for infectious agents. When the eggs are broken, protein concentration increases in the sand, stimulating bacterial and fungal proliferation (Acuña et al. 1999. Appl. Environ. Microbiol. 65:336–338). Nesting female turtles can carry infectious agents. For example, *Vibrio mimicus* has been reported from marine turtle vents in Costa Rica. This infectious agent could be picked up during nesting, when the female has contact with the sand, and later dispersed into the sea water (Phillott et al. 2002. Aust. J. Zool. 50:687–695).

Humans can transport the bacteria and fungus as well. In Costa Rica, Bangladesh, India, and United States there have been reports of human infections due to the ingestion of turtle eggs (Campos et al. 1996. Appl. Environ. Microbiol. 62:1141–1144). Human transport of pathogens during the handling of eggs may occur if hygiene protocols in the conservation centers are inadequate.

The most damaging nest pathogen was *Escherichia coli* and is an important cause of infection in captive animals (George 2005. *In* Lutz and Musick [eds.], The Biology of Sea Turtles, pp. 363–385). *Candida albicans* fungus is a common cause of respiratory infections (Hernandez and Stephen 2001. J. Zoo. Wild. Med. 32:352–359), and *Staphylococcus aureus* causes skin and gastrointestinal infections (Bennett et al. 1986. J. Food Sci. 51:1337–1339). However, there are no previous reports of these bacteria and fungi in turtle nests in Mexico.

In conclusion, this is the first record of infectious bacteria in *Chelonia mydas* nests in the state of Veracruz. The proximity of human communities to the nesting sites as well as poor hygiene in the marine turtle protection centers are possible sources for infective agents in turtle nests.

We thank the Santander community, R. I. Cuevas from the Secretaria de Medio Ambiente y Recursos Naturales (SEMARNAT), and Anais Horden for her assistance in editing the English version of the manuscript. The first author received support from CONACYT, scholarship grant No. 165146.

CHELYDRA SERPENTINA (Snapping Turtle). **DEFORMITY.** To our knowledge, there are no previous reports of a wild adult *Chelydra serpentina* found completely lacking a tail. Here we report an adult female *C. serpentina* observed on 23 July 2009 on the Marsh Trail at Rondeau Provincial Park (Ontario, Canada; 42.27830°N, 81.87108°W; 178 m elev.) with no tail. We have examined many Snapping Turtles with partial tail loss but none to this extent. The vertebrae could be felt down from the base of the tail to just past the cloaca and the skin cleanly covered the end. The cloaca was not distorted and was fully intact and there were no signs of scar tissue or wounds from amputation. There were no other deformities through injury or scarring and the turtle appeared to be a healthy adult female. Photographs available from Christina Davy (contact information below).

COOMBES**, Porfell Wildlife Park and Sanctuary, Trecangate, near Lanreath, Liskeard Cornwall, PL14 4RE, United Kingdom (e-mail: suzanne.coombes@hotmail.co.uk); and **CHRISTINA M. DAVY**, Department of Natural History, Royal Ontario Museum and Department of Ecology and Evolutionary Biology, University of Toronto (e-mail: christina.davy@utoronto.ca).

GOPHERUS POLYPHEMUS (Gopher Tortoise). **GROWTH**. On 3 January 2009 a large adult female Gopher Tortoise was captured at Jonathan Dickinson State Park, Martin County, Florida, USA (JDSP; 27.0061°N, 80.1288°W). This tortoise had been previously captured nearly 20 years (7134 days) earlier on 23 June 1989. At the time of first capture this animal weighed 7995 g and had a carapace length (CL) of 358 mm. Upon recapture this animal weighed 9163 g and had a CL of 375 mm. Both CL measurements were performed using calipers and each is the average of 10 replicate measurements (Timmerman and Roberts 1994. Herpetol. Rev. 24:64). The average growth rate of the recaptured tortoise was 0.87 mm CL/year. There exists a substantial literature on growth rates in Gopher Tortoises across the species' range (Ernst and Lovich 2009. Turtles of the United States and Canada. John Hopkins University Press, Baltimore, Maryland. 827 pp). Ashton and Burke (2007. J Wildl. Mgmt. 71:783–787) report an average growth rate of 1.8 ± 1.9 mm CL/year for adult female tortoises from the Lake Wales Ridge of Florida, a habitat similar to JDSP.

The age of the JDSP tortoise was estimated based on counts of abdominal growth rings. At the time of first capture in 1989 age was estimated to be >29 years. Although this aging method has been shown to be unreliable in adults of some turtle species (Wilson et al. 2003. Herpetologica 59:178–194), we are unable to estimate age using growth models based on tortoise populations from central Florida (Mushinsky et al. 1994. Herpetologica. 50:119–128) or southcentral Alabama (Aresco and Guyer 1999. Herpetologica 55:499–506) because the JDSP tortoise exceeds the asymptotic limit of CL for both the 1989 and 2009 captures.

GRAPTEMYS OUACHITENSIS SABINENSIS (Sabine Map Turtle). **COLORATION**. In 2005, six spotting scope observations of aberrantly colored *Graptemys ouachitensis sabinensis* of both sexes (as determined by tail length and head size) were made in the Old Sabine Bottom Wildlife Management Area (OSBWMA) in Lindale, Texas, USA (J. L. Coleman, pers. obs.). Although the striping pattern was typical for *G. o. sabinensis*, the yellow color was replaced with bright red throughout the body and carapace. These individuals were not reported due to a lack of sufficient photographic evidence. A similarly aberrant female *G. o. sabinensis* was trapped along the same stretch of river on 1 July 2009 while sampling using a fyke net and carphorn (Vogt 1980. Copeia 1980[2]:368–371) (Fig. 1). This female was within the documented size range (i.e., carapace length and mass) for *G. o. sabinensis* and bears the typical markings of the subspecies, with the exception of the red coloration and gold colored eyes (Institute of Natural Resource Sustainability at the University of Illinois at Urbana-Champaign, Illinois Natural History Survey photo voucher INHS 2009r). In addition, several other *G. o. sabinensis* captured during the 2009 field season had similar red patterning on their carapaces but lacked the red facial and limb markings.

The only *Graptemys* species reported to exhibit any level of hypererythrinism (increased red pigmentation**)** are Gibbon's Map Turtle (*G. gibbonsi*), the Ringed Map Turtle (*G. oculifera*), and the Texas Map Turtle (*G. versa*) which are described as having yellow to red carapace markings (Buhlman et al. 2008. Turtles of the Southeast. University of Georgia Press, Athens, Georgia. 251 pp.). No record of a completely hypererythristic map turtle of any species has been reported, nor have red carapace markings been reported for *G. o. sabinensis*. Here we note several different individuals of both sexes over a four-year period, indicating that the trait is not restricted to one sex despite its rarity. Although integumental staining due to environmental influences, such as substrate iron deposits, is possible (J. Harding, pers. obs.), it seems unlikely in the instances reported here, given that our observations were species-specific despite the presence of two other *Graptemys* species and other aquatic turtle species utilizing the same habitat. Additionally, the coloration is not patchy as might be expected in integumental staining and aberrant coloration extends to the iris. We hypothesize that this coloration has a genetic basis; however further validation of this hypothesis is needed.

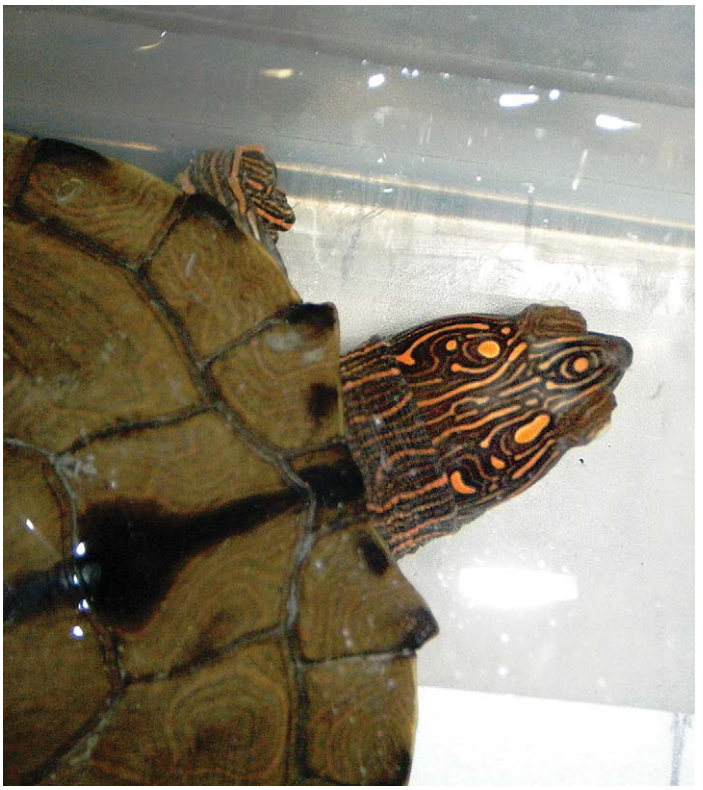

FIG. 1. Aberrent red coloration of a *Graptemys ouachitensis sabinensis* female caught in the Old Sabine Bottom Wildlife Management Area, Lindale, Texas.

Submitted by **SHERI A. SANDERS** (e-mail: sande197@msu.edu), **JESSICA L. COLEMAN,** and **JOHN S. PLACYK, JR.**, Department of Biology, University of Texas at Tyler, 3900 University Blvd., Tyler, Texas 75799, USA.

KINOSTERNON SONORIENSE (Sonoran Mud Turtle). **HATCHLING BEHAVIOR**. For many turtle species, little is known about the behavior of hatchlings in the wild. On 14 August 2009, we observed an interaction between two hatchling *Kinosternon sonoriense* in the Peloncillo Mountains, Coronado National Forest, New Mexico, USA (31.503°N, 109.016°W, NAD83, elev. 1706 m). The interaction lasted ca. 2 min and occurred in a rain-filled rock pool (0.23 m^2) approximately 3.5 cm maximum depth. The water temperature was 25.5°C, and the pool was exposed to full sun. We recorded the last minute of the interaction with a camera, which provided durations of behaviors. When we approached the pool, one hatchling (T1) was on top of the other hatchling (T2), holding onto the carapace of T2 with all 4 limbs. Both turtles were underwater, and it appeared that T2 was attempting to swim away from T1. T1 repeatedly bit at the head and anterior carapace of T2. After 80 sec, T1 bit and held fast to the head of T2 for 4 sec while releasing the carapace of T2. T2 then swam away, and T1 followed and eventually perched on the carapace of T2 for 6 sec. T1 then turned and swam to the opposite end of the pool and attempted to bite a water beetle. At this point we retrieved both hatchlings to determine if they were recaptures and record shell measurements. The midline carapace lengths for T1 and T2 were 22.7 and 22.9 mm, respectively, and the yolk scar and caruncle were still present on both hatchlings.

The context of the behavior we observed is unclear. Most likely we observed precocious courtship or social play, which has been described in hatchling turtles (Cagle 1955. Copeia 1955:307; Morris 1976. Herpetol. Rev. 7:111; Kramer and Burghardt 1998. Ethology 104:38–56). The interaction we observed is similar to the description of courtship behavior for other kinosternids (Mahmoud 1967. Copeia 1967:314–319; Lardie 1975. J. Herpetol. 9:223–227). However, Kramer and Burghardt (1998, *op. cit.*) discussed the possibility of social play instead of courtship. Although we were unable to identify the proper context of the behavior, our observation adds to the limited knowledge about the behavior of hatchling kinosternid turtles in the wild.

We thank K. Locey, B. Stanila, and P. Stone for helpful comments. We also thank the Office of Research and Grants at the University of Central Oklahoma for financial support. This research was conducted under permits issued by the New Mexico Department of Game and Fish (2905) and the U.S. Forest Service

(SUP0080-01).

LEPIDOCHELYS OLIVACEA (Olive Ridley). **EGG SCAVENGING BY FISH.** Sharks and fin-fishes have been documented as significant predators on hatchling sea turtles (Carr 1986. NOAA Tech. Memo. NMFS-SEFC-190, pp. 3–9; Stancyk 1982. *In* K. A. Bjorndal [ed.], Biology and Conservation of Sea Turtles, pp. 139–153. Smithsonian Institution Press, Washington, D.C.). To date, however, there are apparently no reports of fish consumption of sea turtle eggs, presumably because the eggs are buried in a terrestrial nest.

We are studying the ecology of *Lepidochelys olivacea* in the Gahirmatha Marine Wildlife Sanctuary, Orissa, India. The Gahirmatha site is the largest known mass nesting rookery for the Olive Ridley in the world at peak nesting in March and April (Bustard 1976. Tiger Paper 3:3). The Gahirmatha rookery is on a lagoon backed by the Brahmani and Maipura rivers. This mangrove dominated area has notably high fish diversity and productivity (Dash and Kar 1990. The Turtle Paradise: Gahirmatha. Interprint, New Delhi. 295 pp.). Olive Ridleys arrive offshore of Gahirmatha in November and nesting peaks in March and April and continues to May (Dash and Kar 1990, *op. cit.*; Pandav 2000. Conservation and Management of Olive Ridley Sea Turtle Population along the Orissa Coast. PhD. thesis. Utkal University, Bhubaneswar, Orissa. 77 pp.). During the same period, human fishing activities are intensive in the area. In February 2009, three eggs of the Olive Ridley were found in the gut of a catfish, *Arius arius*, which was caught in the Gahirmatha. Diameters of turtle eggs found in the gut ranged from 37.5–37.9 mm.

Unregulated intensive offshore fishing activity has been reported as a major cause for large-scale seaturtle mortality in Orissa (Pandav and Choudhury 1999. Marine Turtle Newsl. 83:10–12). Several thousand dead, gravid Olive Ridleys were found floating on the sea surface during February 2009, possible victims of fishing activities. Therefore, it is presumed that the catfish might have scavenged the eggs from floating dead turtles. Years of research show that Olive Ridleys congregate in small and specific offshore areas of the Orissa Coast, but management programs have failed to provide adequate protection to these congregations from intensive fishing.

SQUAMATA — LIZARDS

AMEIVA AMEIVA (Giant Ameiva) **DIET**. *Ameiva ameiva* is a medium sized teiid lizard found naturally over a wide range at low elevations from Costa Rica (Savage 2002. The Amphibians and Reptiles of Costa Rica: A Herpetofauna Between Two Continents, Between Two Seas. University of Chicago Press, Chicago, Illinois. 934 pp.) to northern South America, and a few Caribbean islands. Introduced populations occur in Florida (Uetz et. al., The JCVI/TIGR Reptile Database, http://www.reptile-database.org, accessed 21 January 2010; Schwartz and Henderson 1985. A Guide to the Amphibians and Reptiles of the West Indies Exclusive of Hispanola. Milwaukee Public Museum, Milwaukee, Wisconsin. 165 pp.). They are active, diurnal foragers known to feed primarily on insects (Duellman 1978. The Biology of an Equatorial Herpetofauna in Amzonian Ecuador. University of Kansas, Lawrence, Kansas. 352 pp.). Lizards and frogs are also known prey items (Duellman *op. cit.*;Vitt and Colli 1994. Can. J. Zool. 72:1986–2008; Pianka and Vitt 2003. Lizards: Windows to the Evolution of Diversity. University of California Press, Berkeley. 346 pp.). Other vertebrate remains have consisted of lizard and frog eggs (Duellman 2005. Cusco Amazonico. Cornell University Press, Ithaca, New York. 433 pp.) The following observations add mammals to the vertebrate taxa eaten by this species.

On 21 November 2003 at 1430 h in the village of Apoteri (confluence of the Rupununi and Rewa rivers), Region 9, Guyana, an adult *Ameiva ameiva* was observed consuming the phalanges of an unidentified species of bat. The lizard had some difficulty swallowing the extended, stiffened but still articulated bones. About 30 minutes later, ca. 5 m distance from where the first observation was made, an *A. ameiva* was observed carrying a bat carcass that was intact, fully furred and appeared relatively fresh. The lizard bit and held the bat in the head/neck region while repeatedly scratching the body with its forefeet. In this manner small pieces of flesh were removed and immediately swallowed. Eventually a hole ca. 1 cm in diameter was created in the bat's skin. At 1520 h the lizard carried the carcass out of view.

These observations were made in the vicinity of a rarely occupied house that supported a large colony of bats. The *A. ameiva* may have been exploiting the natural mortality of this colony as a food source. Alternatively, the lizard could have opportunistically killed a bat that had fallen from its roost.

I thank Peter Taylor for the opportunity to travel in Guyana.

ANOLIS PORCATUS (Cuban Green Anole, Caguayo). **SAUROPHAGY**. *Anolis porcatus* is a Cuban endemic that has also been introduced to Hispaniola (Powell et al. 1990. Amphibia-Reptilia 11:421–425) and Florida (Meshaka et al. 1997. Herpetol. Rev. 28:101–102). It is polytypic (Pérez-Beato 1996–1997. Rev. Biol. Trop. 44/45:295–299), widely distributed in the Cuban Archipelago, and abundant in the gardens associated with homes. Principally in Western Cuba, it is sympatric with several other widely distributed lizards that occur in houses, namely *Anolis sagrei sagrei* and *A. homolechis homolechis*, *Gonatodes albogularis fuscus*, *Hemidactylus haitianus*, *Sphaerodactylus elegans elegans.* Previously published reports on saurophagy in *A. porcatus* include a juvenile *A. homolechis* and younger conspecifics (Socarrás et al. 1988. Misc. Zool. 38:4). Here I provide a second observation of saurophagy in *A. porcatus*, and the first published account of predation on a *Gonatodes a. fuscus*.

At 1630 h on 24 August 2004, an adult (estimated at 50 mm

SVL) female *A. p. porcatus* was observed in the garden of a house in Bejucal (22.925°N, 82.3915°W, elev. 111 m; WGS84), Havana Province, Cuba, devouring a juvenile (~10 mm SVL) *G. a. fuscus*. The *Anolis* lizard was observed with the live juvenile gecko inside its open mouth. The specimen was swallowed poster end first. The *A. porcatus* exhibited some difficulties in swallowing the gecko, probably because of the relatively large size of the juvenile gecko. The posterior part of the gecko body was swallowed quickly but the head was swallowed very slowly. The culmination of the predation was not observed since the animal moved out of view. This episode lasted ca. 15 min.

ANOLIS STRATULUS (Saddled Anole). **DIET**. *Anolis stratulus* is commonly found throughout the Puerto Rico Bank, including the British Virgin Islands (BVI; Powell and Henderson 2009. Natural History of West Indian Reptiles and Amphibians. University Press of Florida, Gainesville.). It is generally considered a trunk-crown species, although in the BVI it is often found closer to the ground than in other parts of its distribution (Lieht 1974. Copeia 1974:215–221; Perry 2005. *In* J. Lazell, Island: Fact and Theory in Nature, pp. 187–188. University of California Press, Berkeley). *Anolis stratulus* is a sit-and-wait predator of small invertebrates, but has also been known to occasionally drink nectar from flowers (Perry and Lazell 1997. Herpetol. Rev. 28:150–151; Powell and Henderson, *op. cit.*) .

In October 2009 we conducted a study of nectivorous bird food preferences on Guana Island, BVI. As part of this study, a sugar water feeder was placed on a small wooden platform hung from a tree. The platform held a bowl of granulated sugar for attracting Bananaquits (*Coereba flaveola*), small local nectivorous bird. Anoles were often observed on the tree and occasionally basked on the platform. On three separate occasions (occurring once on 16 October 2009, and two observations recorded within 30 minutes of each other on 18 October 2009), we observed at least one adult *A. stratulus* drinking from the feeder located on the platform. The feeder contained 10% and 40% sugar solution during the days of observations, respectively. All observations were recorded between 0830 h and 0930 h. In one case, the lizard was feeding along with a Bananaquit. Although another sympatric nectivorous bird, the Antillean Crested Hummingbird (*Orthorhyncus cristatus*), has been reported to sometimes attack Saddled Anoles (Boal 2008. Carib. J. Ornithol. 21:48–49), Bananaquits have not been reported to show such aggression. Over several years, we have also noted *A. stratulus* licking droplets containing dissolved sugar from the bowl following rain, but have never seen them eat granulated dry sugar.

Reptiles capable of utilizing human habitats such as artificial night-lights have an increased potential for such species to become invasive (Perry et al. 2008. *In* Jung and Mitchell [eds.], Urban Herpetology, pp. 239–256. Herpetological Conservation Vol. 3, Society for the Study of Amphibians and Reptiles, Salt Lake, Utah). Although we have never seen *A. stratulus* at night-lights, observations of them supplementing their diet from artificial feeders suggest they have some potential to become invasive, if introduced outside their native range. To date, however, the only record of introduction of this species is associated with a research project (Kraus 2009. Alien Reptiles and Amphibians. Springer, New York).

We thank the Guana Island staff and C. Boal for their assistance and support. Support for this project was provided by The Conservation Agency through a grant from the Falconwood Foundation and by Texas Tech University. This is manuscript T-9-1189 of the College of Agricultural Sciences and Natural Resource Management, Texas Tech University.

ASPIDOSCELIS SONORAE (Sonoran Spotted Whiptail). **SCAVENGING BEHAVIOR.** *Aspidoscelis sonorae* is a moderately large (to 91 mm SVL), parthenogenetic teiid that occurs in northern Sonora, Mexico, southeastern Arizona, and extreme southwestern New Mexico, and known to be an active foraging insectivore (Sredl et al. 2009. *In* Jones and Lovich [eds.], Lizards of the American Southwest: A Photographic Field Guide, pp. 386–389. Rio Nuevo Publishers, Tucson, Arizona). On 24 April 2009 at 0838 h, in the Saguaro National Park East (Rincon Mountains), southeast Arizona, USA, I observed an adult *A. sonorae* scratching in organic litter at the base of a rock outcrop beneath a large saguaro cactus in bloom. As I observed the lizard forage, it tongue-flicked and scratched the substrate with its forefeet and poked the litter with its rostrum. During this foraging process, a dead honeybee (*Apis millifera*) was uncovered. The *A. sonorae* continued to scratch at the litter in the same area glancing over towards the dead honeybee twice, even moving the dead insect with its front right foot once while continuing to dig for a few more seconds (Fig. 1A). However, upon tongue-flicking the bee the *A. sonorae* turned its full attention

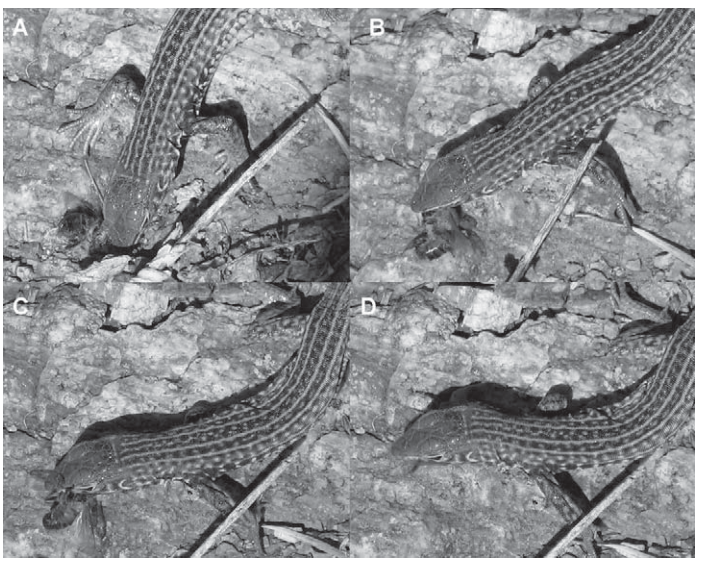

FIG. 1. *Aspidoscelis sonorae* consuming scavenged honeybee at Saguaro National Park East, Arizona, USA.

onto the unresponsive honeybee and after two successive tongue-flicks bit the bee on the head (Fig. 1B) and proceeded to consume the dead honeybee (Fig. 1C–D). To my knowledge, this is the first recorded observation of scavenging by *A. sonorae in situ*.

I thank Wade Sherbrooke for positive identification of the whiptail and comments, and Danny Martin for configuration of the photographs. I would also like to thank Mike Nolan for sharing some of his photographic expertise and hospitality during my trip to Tucson.

Submitted by **DAVID WOJNOWSKI,** University of North Texas, Department of Teaching, Education & Administration, 1155 Union Circle #310740, Denton, Texas 76203-5017, USA; e-mail: david.wojnowski@unt.edu.

BARISIA CILIARIS (Northern Imbricate Alligator Lizard). **ANTIPREDATOR BEHAVIOR**. The defensive loop posture has been observed in other anguid lizards including *Elgaria kingi* (Bowker 1987. Herpetol. Rev. 18:73–75), and *Barisia imbricata planifrons* (Bille 1997. Herpetol. Rev. 28:202). Here we document this defensive behavior in another anguid lizard, *Barisia ciliaris*. This behavior has sequences of occurrence with the following phenotypic categories, as defined by Greene (1988. *In* Gans and Huey [eds.], Biology of the Reptilia, Vol. 16, Ecology B, pp. 1–152. Academic Press, New York), the following models were recognized: 1) locomotory escape (attempting to avoid capture by hiding in forest litter); 2) head hiding (attaining a loop posture, the head is hidden under the tail); and 3) eversion of hemipenes. This behavior is common in most lizards.

Barisia ciliaris is distributed in the mountainous regions of the northern Mexican Plateau, from extreme southern Coahuila to Guanajuato, east to San Luis Potosi, Zacatecas, Durango, and Nuevo Leon (Smith and Taylor 1950. An Annotated Checklist and Key to the Reptiles of Mexico Exclusive of Snakes. Smithsonian Institution, Washington, D.C. 253 pp.; Lemos-Espinal and Smith 2007. Anfibios y Reptiles del Estado de Coahuila, México. Universidad Nacional Autónoma de México y Comisión Nacional Para El Conocimiento y Uso de la Biodiversidad. 550 pp.).

On 28 May 2007 an adult female *Barisia ciliaris* was caught on Cerro El Potosí in the municipality of Galeana, Nuevo Leon, (24.8675°N, 100.248338°W, elev. 3270 m, NAD27). The specimen was found at 1650 h, and was basking on top of a dry log. Upon detection of our presence, it immediately took refuge in a crevice within the log. The lizard was extracted from the log for data collection using a pair of forceps. Immediately after being captured, it rolled its body into a tight coil, attempting to hide its head under its tail. This posture was maintained until the lizard was released a half hour later.

The specimen was 104.9 mm SVL, with 147.2 mm TL, weight 31.5 g, with 17°C dorsal temperature, and 15°C substrate temperature. Surrounding habitat consisted of pine forest with *Pinus hartwegii* as the dominant species.

Financial support was provided through project PAICYT CN-1371-06.

Submitted by **JORGE A. CONTRERAS-LOZANO** (e-mail: pichi_best@hotmail.com), **DAVID LAZCANO** (e-mail: dlazcanov@hotmail.com), and **ARMANDO JESUS CONTRERAS-BALDERAS**, Universidad Autónoma de Nuevo León, Facultad de Ciencias Biológicas, Laboratorio de Herpetología, Apartado Postal- 513, San Nicolas de los Garza, Nuevo León, CP. 66450, México.

CNEMIDOPHORUS OCELLIFER (Spix's Whiptail). **CANNIBALISM.** *Cnemidophorus ocellifer* is a widely distributed neotropical lizard, occurring in Argentina, Bolivia, Paraguay, and throughout Brazil, excluding Amazonia (Vanzolini et al. 1980. Répteis das Caatingas. Acad. Bras. de Ciênc., Rio de Janeiro, Brazil. 161 pp.). The diet of this lizard is composed mainly of arthropods, in which termites, insect larvae, orthopterans, spiders, and beetles are the main food items (Mesquita and Colli 2003. J. Herpetol. 37:498–509; Vitt 1995. Occas. Pap. Oklahoma Mus. Nat. Hist. 1:1–29). Here, we report the first recorded case of cannibalism in a population of *C. ocellifer* from the Caatinga of northeast Brazil.

During an ecological study of a population of *C. ocelllifer* in the Ecological Station of Seridó, Rio Grande do Norte state (06.5767°S, 37.2558°W; datum: WGS84; elev. 192 m), a sample of 70 individuals was collected between September 2008 and August 2009. The stomach contents of an adult female (70.7 mm SVL), collected on 26 June 2009, revealed conspecific ingestion. An undigested juvenile, indicative of recent ingestion, was found whole (32.5 mm SVL, volume = 1170.9 mm^3)(Fig. 1). The juvenile exhibited bite marks on the head, which was pointed toward the distal portion of the predator's stomach. This evidence indicates that the conspecific was captured in an attack and ingested head first, characteristic of a cannibalistic event.

To date, cases of cannibalism in Brazilian lizards have been recorded in nine species belonging to the families Gekkonidae, Liolaemidae, Scincidae, and Tropiduridae (see Siqueira and Ro-

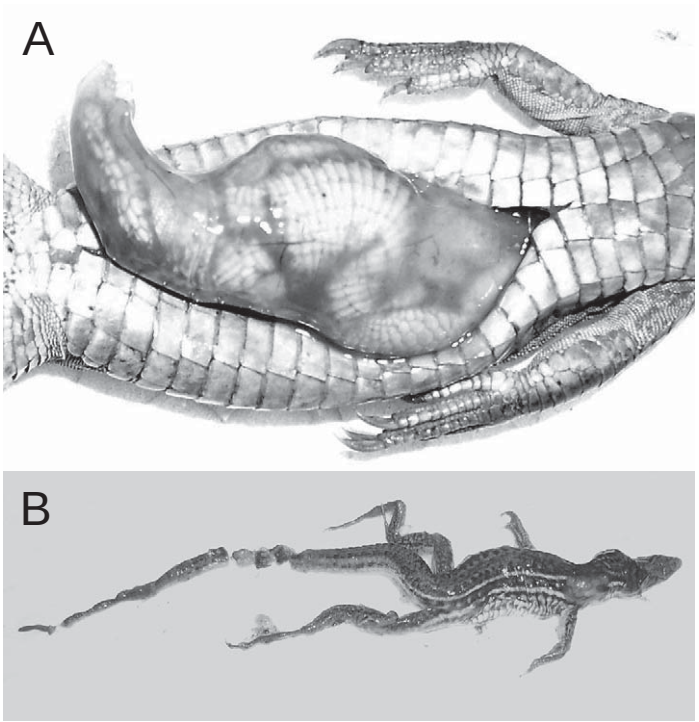

FIG. 1. Cannibalism in *Cnemidophorus ocellifer*: (A) stomach being removed; (B) young conspecific; note signs of bite marks on the head.

cha 2008. S. Am. J. Herpetol. 3:82–87). In the cases involving lizards with sexual dimorphism in body size, and when the sex of the cannibal was reported, the cannibalistic act was always committed by the sex with the larger body size (Siqueira and Rocha 2008, *op. cit.*). In our study, the opposite occurred; cannibalism was practiced by a single female, the sex with the smaller body size in this species.

The frequency of cannibalism occurrence in the population was low (1.4%), a finding consistent with the other reported cases of cannibalism in populations of Brazilian lizards (frequency ranged from 0.7 to 3.8%; Siqueira and Rocha 2008, *op. cit.*). According to Vitt (2000. Herpetol. Monogr. 14:388–400), lizards that capture large prey, such as vertebrates, may not need to forage for several days, owing to the large amount of nutrients provided by the ingested prey. Thus, what seems to be a "rare" event may be an event rarely recorded by investigators.

During the time we recorded the cannibalistic event, we observed an increased number of juveniles in the study area, reflecting a recruitment period. Relatively small body size, lack of experience in detecting potential predators, and the still inefficient recognition of habitat structure make juveniles potential prey for various types of predators (Siqueira and Rocha 2008, *op. cit.;* Vitt 2000, *op. cit.*). The elevated density of juveniles, along with the fact that a predator obtains greater nutritional benefits by capturing conspecifics or phylogenetically similar prey (Mayntz and Toft 2006. J. Anim. Ecol. 75:288–297; Pfennig 2000. Am. Nat. 155:335–345), might have been the main factors that led to the occurrence of this cannibalistic event.

The female specimen of *C. ocellifer* was deposited in the herpetological collection of the Universidade Federal do Rio Grande do Norte, Natal, Brazil (CHBEZ 2681). We thank the Conselho Nacional de Desenvolvimento Científico e Tecnológico (CNPq) for financing the PELD-Caatinga Program entitled Structure and Functioning, and for the research scholarship granted to RFDS (process 127543/2008-2), LBR (process 141993/2006-5), and EMXF (process 304077/2008-9); IBAMA provided a permit (Permit 206/2006 and Process 02001.004294/03-15).

Submitted by **RAUL F. D. SALES** (e-mail: raulsales17@gmail.com), **LEONARDO B. RIBEIRO** (e-mail: ribeiro.lb@gmail.com), and **ELIZA M. X. FREIRE** (e-mail: elizajuju@ufrnet.br), Laboratório de Herpetologia, Departamento de Botânica, Ecologia e Zoologia, Centro de Biociências, Universidade Federal do Rio Grande do Norte, Campus Universitário, 59072-970, Natal, RN, Brazil.

COLEODACTYLUS NATALENSIS (NCN). **PREDATION.** *Coleodactylus natalensis*, described from the Parque Estadual Dunas de Natal (Freire 1999. Bol. Mus. Nac. 399:1–14), is a gecko considered to be endemic to Atlantic forest remnants in Rio Grande do Norte State, Brazil (Sousa and Freire, *in press*). Considered the smallest lizard in South America, it is a denizen of leaf litter within shaded forests (Capistrano and Freire 2009. PublICa 4:48–56; Freire 1999, *op. cit.*; Sousa and Freire, *op. cit.*). Aside from the description of the species (Freire, *op. cit.*), few ecological studies have been performed. Only some aspects of its diet, reproduction, and habitat preference have been published (Capistrano and Freire, *op. cit*; Lisboa et al. 2008. Herpetol. Rev. 39:221; Sousa and Freire, *in press*, Herpetol. Rev.). Few studies are available regarding prey-predator relationships between reptiles and arthropods within Brazilian communities, due to the time required for sampling and the elusive habits of many reptile species (Rocha and Vrcibradic 1998. Ciência e Cultura 50:364–368). Given the limited distribution of this species within remnant forests, additional information on its ecological relationships are essential to understanding its life history. Here, we report on an observation of predation on *Coleodactylus natalensis* by the ant, *Dinoponera quadriceps*.

The ant genus *Dinoponera* contains species with body sizes varying from 3–4 cm (Paiva and Brandão 1995. Ethol. Ecol. Evol. 7:297–312). *Dinoponera* ants are described as solitary foragers with predominantly carnivorous habits, ranging from humid forest soil to dry savannas (Fourcassié and Oliveira 2002. J. Nat. Hist. 36:2211–2227). The neotropical ant *D. quadriceps* is a typical queenless species of the subfamily Ponerinae, found in the isolated forest range (known locally as "Brejos de Altitude") in the semiarid Caatingas, Cerrado, and Atlantic Forest (Paiva and Brandão, *op. cit.*).

During a study of behavioral ecology on 7 March 2009, in the Parque Estadual Mata da Pipa (PEMP), municipality of Tibau do Sul, State of Rio Grande do Norte, Brazil (6.24861ºS, 35.05750°W; datum WGS84; elev. 63 m), PAGS saw an adult male *C. natalensis* (18.3 mm SVL) in the leaf litter of dense forest at 1100 h. The gecko crossed paths with a *D. quadriceps* (~3 cm from the anterior tip of the head to the posterior end of the abdomen) that was foraging in the near vicinity. The ant immediately grabbed the gecko by the neck with its jaws and proceeded to carry it to the nest. The animals were intercepted in order to collect the lizard.

This is the first record of a known predator for *C. natalensis*. We deposited the specimen (CHBEZ 2518) in the herpetological collection of the Universidade Federal do Rio Grande do Norte, Natal, Brazil. We thank the Conselho Nacional de Desenvolvimento Científico e Tecnológico (CNPq) for the research scholarship granted to PAGS (process 127543/2008-2) and EMXF (process 304077/2008-9).

Submitted by **PABLO AUGUSTO GURGEL DE SOUSA** (e-mail: pabloguitar2@hotmail.com), and **ELIZA MARIA XAVIER FREIRE** (e-mail: elizajuju@ufrnet.br), Laboratório de Herpetologia, Departamento de Botânica, Ecologia e Zoologia, Centro de Biociências, Universidade Federal do Rio Grande do Norte, Campus Universitário Lagoa Nova, CEP 59072-970, Natal, RN, Brazil.

COLEODACTYLUS NATALENSIS (NCN). **DIET.** *Coleodactylus natalensis*, described from the Parque Estadual Dunas de Natal (Freire 1999. Bol. Mus. Nac. 399:1–14), is considered endemic to Atlantic Forest remnants in Rio Grande do Norte State, Brazil (Sousa and Freire, *in press*). Considered the smallest lizard in South America, it is a shaded forest leaf-litter dweller (Capistrano and Freire 2009. PublICa 4:48–56; Freire 1999. Bol. Mus. Nac. 399:1–14; Sousa and Freire, *op. cit.*). The diet of *C. natalensis* in Parque Estadual Dunas de Natal is mostly arthropods. Isopods and spiders are the most frequent prey based on numbers, volume, and frequency, implying a preference for large prey that is less abundant in leaf litter (CMCAL, pers. obs.). *Coleodactylus meridionalis* has a similar diet, differing only in its relatively larger prey (Dias et al.

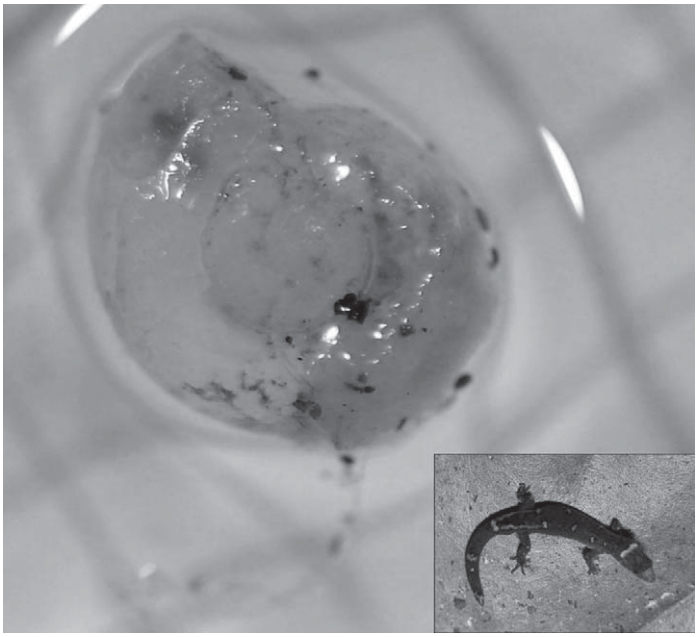

FIG. 1. The *Streptaxis* sp. snail taken from the stomach of *Coleodactylus natalensis* (inset).

2003. Herpetol. Rev. 34:142–143). *Coleodactylus septentrionalis* feeds mainly on termites (Isoptera) and earwigs (Dermaptera) (Vitt et al. 2005. Herpetol. Monogr. 19:137–152). *Coleodactylus amazonicus* seems to prefer collembolans (Collembola) and mites (Acari) (Ramos 1981. Acta Amaz. 11:511–526; Vitt et al., *op. cit.*). Though members of the genus *Coleodactylus* consume a relatively diverse assemblage of invertebrate prey, records of mollusk consumption are lacking. Hence, here we provide the first report of mollusk ingestion in the genus.

During a study of the structure of lizard assemblages in the Parque Estadual Mata da Pipa (PEMP), municipality of Tibau do Sul, State of Rio Grande do Norte, Brazil (6.24861ºS, 35.05750°W; datum WGS84; elev. 63 m), we examined the stomach contents of 16 *C. natalensis*. During this examination, we found a snail of the genus *Streptaxis* (Gastropoda, Streptaxidae) (2.1 mm long, 1 mm width, 10.99 mm^3 volume; Fig. 1), in the stomach of an adult female (20.3 mm SVL, 0.14 g) captured at 1230 h on 13 March 2009 (dry season) in the leaf litter of dense forest.

We deposited the *C. natalensis* (CHBEZ 2509) in the herpetological collection of the Universidade Federal do Rio Grande do Norte, Natal, Brazil. We thank the Conselho Nacional de Desenvolvimento Científico e Tecnológico (CNPq) for the research scholarship granted to PAGS (process 127543/2008-2) and EMXF (process 304077/2008-9). We thank Marc Hayes for helpful comments on this note and Roberto Lima for identifying the snail.

DIPLOGLOSSUS DELASAGRA (Cuban Pale-necked Galliwasp). **REPRODUCTION AND PARENTAL CARE.** Three endemic species of the subfamily Diploglossinae occur in Cuba, including *Diploglossus delasagra*, *D. garridoi*, and *D. nigropunctatus* (Thomas and Hedges 1998. Copeia 1998:97–103), however, information available on the natural history of these species is scarce. This is probably due to the cryptic and elusive habits exhibited by members of this genus, as observed in most anguids. For this reason, we feel that any attempt to gather and provide information on these species may be relevant to the current knowledge and understanding of their biology.

On 15 June 2007, a gravid female *D. delasagra* was collected in the leaf litter of a woodland patch by an unpaved road connecting the Las Palmas rural community (22.200889°N, 78.8394861°W, WGS84) and the town of Enrique Varona (Falla) (22.172875°N, 78.2002889°W), Chambas municipality, Ciego de Avila province, Cuba. These localities are separated from one another by ca. 6.4 km. The animal was brought to the Centro de Investigaciones de Ecosistemas Costeros (CIEC), and kept in captivity in order to collect data on its reproductive biology.

The individual was kept alive in a plastic bucket placed in a dark room for about 48 h from the time it was collected until it was brought to CIEC. Afterwards, the lizard was placed into a 170 × 190 mm plastic terrarium. One sample of the nearby semideciduous forest leaf litter was taken, allowing us to have a 3–4 cm depth layer at the bottom of the container. It was kept at room temperature, avoiding direct sunlight and thus excessive dehydration. Every two days, the leaf litter was sprayed with tap water to maintain relatively constant moisture.

The animal was periodically fed by providing forest soil-dwelling invertebrates, taking into consideration the feeding preferences for this species (Martínez Reyes and Moreno 2003. *In* L. Rodríguez Schettino [ed.], Anfibios y Reptiles de Cuba, pp. 90–97. UPC Print, Vaasa). The invertebrates were mostly spiders, ants, termites, and small mollusks. Around the mouth of the container, a thick mesh was firmly tied up to keep prey from escaping, and provide the lizard access to fresh air.

Behavioral observations were conducted during daylight hours in 90 min intervals for four days, 5–8 July 2007, between 0730 to 1900 h. The observations also comprised one 24 h cycle, but only on 9 July. Each observation period lasted 15 min, which totalled 12 h of direct observations. During the behavioral experiment, leaf litter temperature ranged between 27.5 and 30.6°C.

The female measured 96.0 mm SVL and 8.58 g body mass, and laid six eggs, which coincided with Schwartz and Henderson (1991. Amphibians and Reptiles of the West Indies. Descriptions, Distributions, and Natural History. University of Florida Press, Gainesville. xvi + 720 pp.); however, Cuban species of this genus may have up to nine eggs per clutch (Martínez Reyes and Moreno, *op. cit.*). Oviposition took place between 19 and 25 June; the clutch size was six eggs and after four days (29 June) measurements were made. Three eggs were chosen to be measured because they were laid at a shallow depth of 10 mm. The resulting egg measurements were slightly lower than those obtained by Barbour and Ramsden

FIG. 1. Female *Diploglossus delasagra* protecting its clutch with the body bent around one egg (arrow).

(1919. Mem. Mus. Comp. Zool. 47:69–213) (8.1 × 14.3 mm, 496.0 mm^3 vs. 9 × 17 mm, 720.6 mm^3).

In this study, the female was observed with her body coiled around one of the eggs 11–12 h post-laying (Fig. 1), which coincides with observations made on a female *D. nigropunctatus* (Barbour and Shreve 1937. Bull. Mus. Comp. Zool. 80:377–387). We noticed that the female remained indifferent to several kinds of stimuli such as camera flash and handling of the container. We also observed the female to rest her snout on one egg. Similar behavior has been described by Savage (2002. The Amphibians and Reptiles of Costa Rica: A Herpetofauna Between Two Continents, Between Two Seas. Univ. Chicago Press, Chicago, Illinois. 934 pp.) for a female *D. bilobatus* (Costa Rica).

On some occasions, when the female was completely hidden in the leaf litter layer, we searched the top layer to be certain of her position relative to her clutch. She never showed any evasive behaviors. A few times, she slowly buried herself into deeper levels of the leaf litter, but always stayed close (30–50 mm) to her eggs. Similar behavior was also observed in *D. nigropunctatus* by Barbour and Ramsden (*op. cit.*). The female did not display any aggressive behavior while we poked gently around the eggs, contrary to observation for *D. monotropis* (Central and South America) by Solórzano (2001. Fauna 2:8–12). In our case, the female remained indifferent to this kind of stimulus, but always kept an alert posture during disturbance.

No active feeding behavior was observed during the period in captivity, although food was always available. We interpret this as an indication that nest attendance was a priority, and which might be an energetically low-cost activity. However, during nocturnal cycles of observations, the female spent most of the time under the leaf litter, such that foraging might have gone undetected given that this species is thought to exhibit nocturnal habits (Martínez Reyes and Moreno, *op. cit.*).

Our observations on captive *D. delasagra* indicate that the adult female maintains a close and persistent physical proximity to its clutch, which is supported by observations by Greene et al. (2006. S. Am. J. Herpetol. 1:9–19). Other descriptions dealing with the parental care in this group of reptiles such as ingestion of embryonic remains and the closeness to the neonates by the female parent were not possible in this study, as the female was found dead on the morning of 11 July 2007. The cause of death is unknown.

DRACO BECCARII (Beccar's Flying Dragon). **NESTING**. Nesting is often little-known in secretive animals such as reptiles, and lizards are no exception (Perry and Dmi'el 1994. Amphibia-Reptilia 15:395–401). Anecdotal observations can pave the way for quantitative studies that uncover behaviors associated with nesting and their evolutionary history, and the influence of nest site choice on reproductive success. Little information exists on the nesting habits of flying dragons, genus *Draco*.

On 9 July 2009 at 1245 h we discovered a nesting flying lizard (*Draco beccarii*) near Lapago Base Camp, ~7 km from Labundo Bundo, on the island of Buton in Sulawesi, Indonesia. The mother was on the ground with her head over an open chamber with three visible eggs in the bottom (Fig. 1). The eggs were not dimpled and were arranged in one layer (egg sizes, length followed by width: #1 = 12.6, 7.1; #2 = 12.2, 7.1; #3 = 12.7, 7.2). The mother (SVL = 76.4 mm, TL = 147.2 mm, mass = 5.5 g) was captured for photographs and measurements, palpated and found to contain no other eggs, and released at the nest site the following day. We backfilled the nest (depth to the top egg = 1.8 cm; chamber depth = 3.1 cm; chamber diameter ~3 cm). The nest site was in a small (~10 × 10 cm) spot of bare ground in an area with scattered leaf litter, on a scarcely used trail in rainforest. There was a sparse understory but

COLOR REPRODUCTION SUPPORTED BY THE THOMAS BEAUVAIS FUND

FIG. 1. A female *Draco beccarii* sits over her nest cavity with three eggs she just laid.

no shrubs near the nest site. The overstory was >95% canopy cover and was not visibly different than the surrounding area. The distance to the nearest tree was 1.5 m and there were several other trees within 10 m. The soil was luvisol and was moist but not saturated. Weather conditions during the observation were mostly sunny and ~27ºC, and followed a day of similar conditions but with some patchy, light rainfall.

Two nesting *D. beccarii* were similarly observed in July, 2000 (Table 1). Nine additional individuals were recorded as gravid females due to palpation, dissection, or terrestrial behavior (Table 1). The mean body sizes of gravid or nesting *D. beccarii* were SVL = 72.2 ± 9.99 mm SD; TL = 148.7 ± 9.94 mm SD; mass = 7.0 ± 1.29 g SD. Based on our observations the nesting season in *D. becarrii* spans (at least) all of July and August on Buton (Table 1).

TABLE 1. Female *Draco becarrii* observed or captured during the nesting season on Buton, Sulawesi. 1 = range for the previous 24 hrs (minimum-maximum); 2 = discovered while nesting, captured and palpated; 3 = captured by hand and palpated; 4 = captured in pitfall trap and palpated; 5 = discovered while nesting, not captured; 6 = sighted on ground but not captured 7 = found dead, dissected; S = sunny, C = cloudy, R = rainy; numbers after weather indicate rainfall amounts over the previous 24 hrs. * Sex determined by lack of colorful dewlap.

We are unaware of any published observations of this or other *Draco* species nesting in the wild, although there may be published information in non-indexed regional journals. The nesting behavior of *D. volans* and *D. spilopterus* in captivity was described by Magdefrau (1992. The Vivarium 4:13–15) and Card (1994. Herpetol. Rev. 25:65), respectively. It appears that *D. beccarii* does not seek out sunny places for nesting like most agamids, but rather nests more or less randomly with respect to canopy openness like many other rainforest-inhabiting tropical agamids (Greer 1989. The Biology and Evolution of Australian Lizards. Surrey Beatty and Sons, Chipping Norton, New South Wales). However, *Draco* appears to conform to the agamid pattern of nesting in the substrate on the forest floor (Greer 1989, *op. cit.*), despite its highly arboreal nature. In fact, it is possible that *Draco* only leaves the trees for nesting. Clutch size in the present observation fell between that reported for *D. melanopogon* (mean = 2, N = 14 and N = 90) and *D. volans* (mean = 4, N = 20) by Hendrickson (1966. Bull. Raffles Mus., Singapore 34:53–71) and Shine et al. (1998. J. Zool. Lond. 246:203–213).

We thank Operation Wallacea and Phil Wheeler for logistical support, and the many volunteers for field assistance.

ENYALIUS PERDITUS (NCN) and ***ENYALIUS BILINEATUS*** (NCN). **PREDATION.** *Enyalius perditus* and *E. bilineatus* are typical Brazilian Atlantic forest species. However, *E. perditus* inhabits areas with humid vegetation and closed canopies, whereas *E. bilineatus* has a preference for more open areas (Jackson 1978. Arq. Zool. 30:1–79). Nevertheless, both species are sympatric with the leaf-litter spider, *Ctenus ornatus* (Ctenidae). This spider is nocturnal, spends most of its time hidden inside cracks or holes, has a preference for areas with dense vegetation, and avoids antropized areas (Almeida et al. 2000. Rev. Brasil. Biol. 60[3]: 503–509). We observed two separate predation events involving this spider on the young of two different *Enyalius* species—the first on *E. bilineatus* and the second on *E. perditus*. We believe these observations to be the first records of this spider predating on these respective lizard species.

On 14 October 2008, in the Municipal Park of Lajinha, in the municipality of Juiz de Fora, state of Minas Gerais, Brazil (21.792417°S, 43.380889°W; WGS84, 893 m elev.), we observed a young *E. bilineatus* (31.3 mm of SVL) being consumed by a *C. ornatus* spider with a cephalothorax length of 28.2 mm during the inspection of a funnel trap used in a reptile survey study. This animal had already been captured by the spider and was held by the neck region at the moment of the initial observation, with no signs of necrosis, which suggests that the capture probably occurred a short time before it. On 22 October, 2008, a young *E. perditus* (31.8 mm of SVL) was found being ingested by a spider of 21.8 mm (cephalothorax length). Upon intial observation, the spider was present inside the trap together with the lizard, with no signs of a predation event. As we initially attempted to take the lizard out of the trap, it evaded capture and approached the spider. It was then captured by the spider, also being held at the neck region. The observation of the necrosis evolution in both animals was carried out and, after about 7 h they were totally consumed, with the exception of a part of each animal's tail.

Because they inhabit the same environment, we believe that this kind of predation may commonly occur in the area. The spiders were deposited in the collection of terrestrial invertebrates of Universidade Federal de Juiz de Fora (CIUFJF 002–003). We thank the Cordenação de Aperfeiçoamento de Pessoal de Nível Superior (CAPES) for financial support and also IBAMA for issuing collection permit 16895-1.

GEKKO GECKO (Tokay Gecko). **PREY.** *Gekko gecko* is an introduced species to Florida from SE Asia (King and Krakauer 1966. Quart. J. Florida Acad. Sci. 29:144–154). Known to be a highly aggressive predator (Smith 1935. The Fauna of British India. Reptilia and Amphibia Vol. II. Taylor and Francis, London. xiii + 440 pp.), *G. gecko* preys on a wide variety of food items in Florida (Meshaka et al. 1997. Florida Field Nat. 25:105–107; Love 2000. Herpetol. Rev. 31:174) and in SE Asia (Aowphol et al. 2006. Amphibia-Reptilia 27:491–503). *Romalea guttata* (Eastern Lubber Grasshopper), native to SE United States, is a chemically defended arthropod, which produces a highly complex defensive secretion when stressed (Whitman et al. 1991. Can. J. Zool. 69:2100–2108). Yosef and Witman (1992. Evol. Ecol. 6:527–536) reported that *Lanius ludovicianus* (Loggerhead Shrike) was the only species of 21 birds and lizards observed during laboratory and field studies to successfully feed on *R. guttata*. Common reactions by various species having ingested *R. guttata* are gagging, regurgitation, and death (Yosef and Witman 1992, *op. cit*.). Here we report the observation of an adult *G. gecko* successfully predating on an adult *R. guttata*.

On 6 June 2008 at ca. 0945 h (DST), an adult *G. gecko* was observed on the eastern-facing wall of a house in a residential community in Broward County, Florida, USA (26.0490°N, 80.3984°W). After turning to leave the area where the gecko was observed, a rustling sound followed by a crunching sound was heard. Upon investigation, the adult *G. gecko* was observed to have seized an adult *R. guttata* cross ways in its jaws. The gecko then moved to another wall of the house where it finished eating the grasshopper. The entire process took approximately ten minutes and at no time did the gecko flinch, gag, or regurgitate the grasshopper. Repeated examinations (1, 3, and 24 h) afterwards of the gecko and feeding locations produced no evidence of regurgitation.

Submitted by **JEFFREY S. BEAUCHAMP** (e-mail: jbeach@ufl.edu), and **FRANK J. MAZZOTTI**, University of Florida, Ft. Lauderdale Research and Education Center, 3205 College Ave, Davie, Florida 33314, USA.

GERRHOSAURUS NIGROLINEATUS (Black-lined Plated Lizard). **ENDOPARASITES.** *Gerrhosaurus nigrolineatus* is known from Uganda, Rwanda, Tanzania, northeastern South Africa, west to Congo-Brazzaville, southwest to Angola (Spawls et al. 2002. A Field Guide to the Reptiles of East Africa. Academic Press, San Diego. 543 pp.). We established an initial helminth list for *G. nigrolineatus* by examining three specimens (two females, one male) (SVL = 160, 132, 143 mm) collected in February 1968 from Rakai District, Uganda and deposited in the Natural History Museum of Los Angeles County, Los Angeles, California USA (LACM 39470, 39474, 39483). The lizards were opened by a mid-ventral incision. The digestive tract was removed and examined for endoparasites using a dissecting microscope. The body cavity was also searched. Six cestodes were found, three in the small intestines of LACM 39474 and 39483. The cestodes were cleared in xylol, regressively stained in haematoxylin, mounted in balsam, studied under a compound microscope and identified as *Oochoristica truncata* (prevalence, lizards infected/lizards examined × 100 = 67%). Cestodes were deposited in the United States National Parasite Collection (USNPC), Beltsville, Maryland, USA as *Oochoristica truncata* (USNPC 102415).

Oochoristica truncata is likely the most common tapeworm in reptiles in southern Africa and has been reported from agamid, chamelonid, gekkonid and scincid lizards and boid and colubrid snakes (Spasskii 1951. Anoplocephalate Tapeworms of Domestic and Wild Animals. Acad. Sci. USSR, Moscow. 783 pp.; Goldberg and Bursey 2004. Afr. Zool. 39:111–114; Goldberg et al. 1999. Comp. Parasitol. 66:78–80). Although the life cycle of *O. truncata* is not known, Conn (1985. J. Parasitol. 71:10–16) reported beetles acted as intermediate hosts for the congener, *O. anolis*. *Oochoristica truncata* in *Gerrhosaurus nigrolineatus* represents a new host record and the Gerrhosauridae represents a new host family record for *O. truncata*.

We thank Christine Thacker (LACM) for permission to examine specimens and Cecilia Nava (Whittier College) for assistance with dissections.

Submitted by **STEPHEN R. GOLDBERG,** Department of Biology,Whittier College, Whittier, California 90608, USA (e-mail: sgoldberg@whittier.edu); and **CHARLES R. BURSEY,** Department of Biology, Pennsylvania State University, Shenango Campus, Sharon, Pennsylvania 16146, USA (e-mail: cxb13@psu.edu).

GONATODES ATRICUCULLARIS (Cajamarca Gecko). **ENDOPARASITES.** *Gonatodes atricucullaris* is known only from Bellavista, Cajamarca Department, Peru (Uetz and Hallermann 2009. www.reptile-database.org. Accessed 2 February 2010). To our knowledge there are no reports of helminths from this species. The purpose of this note is to establish the initial helminth list for *G. atricucullaris*.

Four *G. atricucullaris* (mean SVL = 31.5 mm ± 1.3 SD, range: 30–33 mm SVL) collected in November 1968, from Bellevista, (7.06667°S, 76.5333°W, datum WGS84; elev. 295 m) Cajamarca Department, Peru, were borrowed from the herpetology collection

of the Natural History Museum of Los Angeles County (LACM), Los Angeles, California: LACM 49352, 49355, 49358, 49359.

The body cavities were opened and the digestive tracts were removed. Contents were examined under a dissecting microscope. Found in the stomachs of LACM 49355 and 49359 were 5 and 21 mature nematodes, respectively. In the large intestine of LACM 49352 was one 3rd stage larva. These were each placed in a drop of glycerol on glass slide, cover-slipped and identified using a compound microscope as *Physaloptera retusa.* Prevalence (number infected lizards/total lizards examined × 100) was 75%. Mean intensity (mean number of worms/infected host ± SD) was 9.0 ± 10.6 SD, range: 1–21. Voucher helminths were deposited in the United States National Parasite Collection (USNPC), Beltsville, Maryland, USA as USNPC 102885.

Physaloptera retusa is widely distributed in lizards in the western hemisphere and is known from North and South America, the Caribbean and Mexico (Goldberg et al. 2007. Comp. Parasitol. 74:327–342). Species of *Physaloptera* utilize insects as intermediate hosts; lizards become infected by ingesting insects that contain infective larvae (Anderson 2000. Nematode Parasites of Vertebrates: Their Development and Transmission 2nd ed. CABI Publishing, Oxfordshire, UK. 650 pp.) *Gonatodes atricucullaris* represents a new host record for *Physaloptera retusa*.

We thank C. Thacker (LACM) for permission to examine specimens and O. Mac (Whittier College) for assistance with dissections.

Submitted by **STEPHEN R. GOLDBERG,** Whittier College, Department of Biology, Whittier, California 90608, USA (e-mail: sgoldberg@whittier.edu); and **CHARLES. R. BURSEY**, Pennsylvania State University, Shenango Campus, Department of Biology, Sharon, Pennsylvania 16146, USA (e-mail: cxb13@psu.edu).

GYMNODACTYLUS GECKOIDES (Naked-toed Gecko). **ENDOPARASITES.** *Gymnodactylus geckoides* is known from northeastern Brazil to Central Brazil (Vanzolini 2004. An. Acad. Brasil. Cien. 76:663–698). Three subspecies are recognized (Vanzolini, *op. cit.*). Kossack (1910. Centralbl. Backteriol. Parasit. 56:114–120) found a digenean in a liver cyst of *G. geckoides*. Herein we add to the helminth list for this species.

Thirty-five *G. geckoides amarali* (mean SVL = 38.8 mm ± 9.7 SD, range = 22–49 mm) collected in Brazil, Tocantins State, Caseara (09.2111111°S, 49.8369444°W; WGS 84; elev. 210 m) in September–October 2005 by LJV and deposited in the Sam Noble Oklahoma Museum of Natural History, Norman, Oklahoma as OMNH 42362–42396 were examined for helminths.

The body cavity was opened and the digestive tract was removed and examined under a dissecting microscope. Stomachs had been previously removed and were not available for examination. Eight female nematodes were found in the large intestine of OMNH 42366. Prevalence (infected lizards/lizards examined × 100) was 3%. Nematodes were cleared in glycerol, studied under a compound microscope and identified as *Spauligodon oxkutzcabiensis.* They were deposited in the United States National Parasite Collection, Beltsville, Maryland, USA as USNPC 102694.

Spauligodon oxkutzcabiensis is known from lizards in Mexico, Central and South America. Records are listed in Goldberg and Bursey (2009. Herpetol. Rev. 40:224). To this list should be added: *Microlophis occipitalis* from Peru (Goldberg and Bursey 2009. Salamandra 45:125–128); *Phyllodactylus inaequalis, P. johnwrighti, P. microphyllus* from Peru (Goldberg and Bursey 2010. Comp. Parasitol. *in press*) and *P. unctus* from Mexico (Goldberg and Bursey 2010. Herpetol. Rev. 41:84–85). The life cycle of *S. oxkutzcabiensis* is not known, however, infection of the congener *S. giganteus* occurs by ingestion of eggs in fecal contaminated substrate (Goldberg and Bursey 1992. J. Parasitol. 78:539–541). *Spauligodon oxkutzcabiensis* in *G. geckoides* is a new host record. Brazil is a new locality record.

We thank Cecilia Nava (Whittier College) for assistance with dissections.

HEMIDACTYLUS MABOUIA (Tropical House Gecko). **CANNIBALISM**. Intraspecific predation of juveniles by adult lizards has been reported in some species (Polis and Myers 1985. J. Herpetol. 19:99–107; Germano and Williams 1994. Herpetol. Rev. 25:26–27; Siqueira and Rocha 2008. S. Am. J. Herpetol. 3:82–87). Among 67 stomachs examined of *Hemidactylus mabouia* specimens, only a single adult stomach contained a conspecific juvenile (Zamprogno and Teixeira 1998. Herpetol. Rev. 29:41–42). Herein, we report the second observation of cannibalism in this gecko.

At ca. 0100 h on 4 January 2010, outside of a house in an urban area (22.9091667°S, 47.0477778° W, 680 m elev.), municipality of Campinas, State of São Paulo, southeastern Brazil, we observed an adult *H. mabouia* with the head of a conspecific juvenile inside its mouth (Fig. 1). The adult gecko had a SVL of ca. 120 mm and the smaller lizard was ca. 50 mm SVL. However, ingestion of the

FIG. 1. An adult *Hemidactylus mabouia* preying upon a conspecific juvenile in municipality of Campinas, State of São Paulo, Brazil.

juvenile was not successful by the adult gecko and the juvenile escaped. We do not know if the unsuccessful predation is result of photographer disturbance. JPP thanks CNPq for financial support.

HOLBROOKIA APPROXIMANS (Speckled Earless Lizard). **PREDATION.** This phrynosomatid lizard has a wide distribution throughout the southwestern United States and much of the northwest central portion of Mexico (Conant and Collins 1998. A Field Guide to the Reptiles and Amphibian of Eastern and Central North American, 3rd ed. Houghton Mifflin, Boston, Massachusetts. 450 pp.; Stebbins 2003. A Field Guide to Western Reptiles and Amphibians, 3rd ed. Houghton Mifflin, New York. 533 pp.). Smith (1979. Handbook of Lizards. Comstock Publishing Associates, Cornell University Press, Ithaca, New York. 557 pp.) mentioned that a specimen of this species had been consumed by a large *Bufo alvarius* (=*Incilius alvaria*), and another by a "small hawk" but did not provide any specific species. The Burrowing Owl (*Athene cunicularia*) has a wide distribution throughout much of North and South America including the Caribbean (American Ornithologists Union 1983.Check-list of North American Birds, 6th ed. Allen Press, Inc. Lawrence, Kansas. 877 pp.; Wellicome and Holroyd 2001. J. Raptor Res. 35:269–273). This species has been the focus of extensive study in the last twenty years (McDonald et al. 2004. The Burrowing Owl (*Athene cunicularia*): A Technical Conservation Assessment. USDA Forest Service, Rocky Mountain Region. http://www.fs.fed.us./r2/projects/scp/assessments/burrowingowl.pdf). Reports of its food habits have been documented (Coulombe 1971. Condor 73:162–176; Grant 1965. Loon 37:2–17; Marti 1974. Condor 76:45–61; Valdez-Gómez 2003. Dieta del tecolote llanero occidental *Athene cunicularia* [Bonaparte 1825], durante su estancia invernal en el bajío mexicano. Las Agujas Zapopan, Universidad de Guadalajara. Licienciatura 41 pp.) but most predation records are for mammals, birds, and invertebrates, with a limited number of herpetofaunal species (Moulton et al. 2006. J. Wildl. Manag. 70:708–716). Here, we add *Holbrookia approximans* as prey to this owl's diet.

On 12 December 2002, during analysis of regurgitated owl pellets collected during a survey on the winter ecology of *A. cunicularia*, a skull (14.3 mm) of an adult *H. approximans* was discovered in one of 128 pellets examined from Llano de la Soledad (25.0958111°N, 100.8104056°W; datum WGS84, elev. 1850 m), in the municipality of Galeana, Nuevo Leon, Mexico. Native vegetation of the study area consists of open grassland bordered by an association of *Larrea tridentata*, *Flourensia cernua*, *Rhus microphylla*, *Prosopis* sp., and *Acacia* sp. The study area has been modified by extensive potato culture.

IGUANA IGUANA (Green Iguana). **PREDATION.** Both juvenile and adult Green Iguanas are preyed on by a wide variety of avian, mammalian, and reptilian predators (Greene et al. 1978. J. Herpetol. 12:169–176; Rivas et al. 1998. Herpetol. Rev. 29:238–239). In general, juvenile Green Iguanas suffer higher mortality from birds while larger size classes are taken more frequently by reptilian and mammalian predators (Rivas et al. 1998, *op. cit*). Here we report a nocturnal predation event on a subadult *Iguana iguana* by an avian predator at the Iguana Verde Foundation (IVF) located in the Gandoca-Manzanillo Wildlife Refuge (09.63818°N, 82.70496°W; datum WGS84), Limón, Costa Rica. The IVF is an education and conservation breeding facility with several natural iguana open-air exclosures (up to 2000 m^2) of mixed male and female age classes.

At 1830 h on 28 May 2009, we observed an adult Spectacled Owl, *Pulsatrix perspicillata*, flying overhead with a subadult (ca. 20 cm SVL) *I. iguana* in its talons. Nocturnal predation events are observed rarely and to our knowledge this is the first account of predation on *I. iguana* by any avian species in the family Strigidae and augments our knowledge of nocturnal predators of Green Iguanas.

JAPALURA SWINHONIS (Swinhoe's Tree Lizard). **SPINAL DEFORMITY**. Scoliosis and kyphoscoliosis have been recorded in lizards, snakes, and a few chelonians and crocodilians, and may appear at birth or hatching, or after some period of apparent normal skeletal growth and development (Frye 1991. Biomedical and Surgical Aspects of Captive Reptile Husbandry. Krieger Publ. Co., Malabar, Florida. 637 pp.). As for the latter, the etiologies may be due to an expression of sub-lethal genetic defects, or may be caused by some acquired environmental condition such as thermal or physical trauma, metabolic bone diseases, or osteomyelitis (Frye, *op. cit*.).

At ca. 1000 h on June 4 2008, JHW observed two male *Japalura swinhonis* engaged in a territorial dispute next to a paved road in Yunlin County, Taiwan (23.6092ºN, 120.5784ºE; TWD97, elev. 178 m). After capturing one of them as part of a study of internal parasites, we noted that it had a deformed spine and base of tail (Fig. 1). The lizard had a SVL, tail length, and mass of 66 mm,

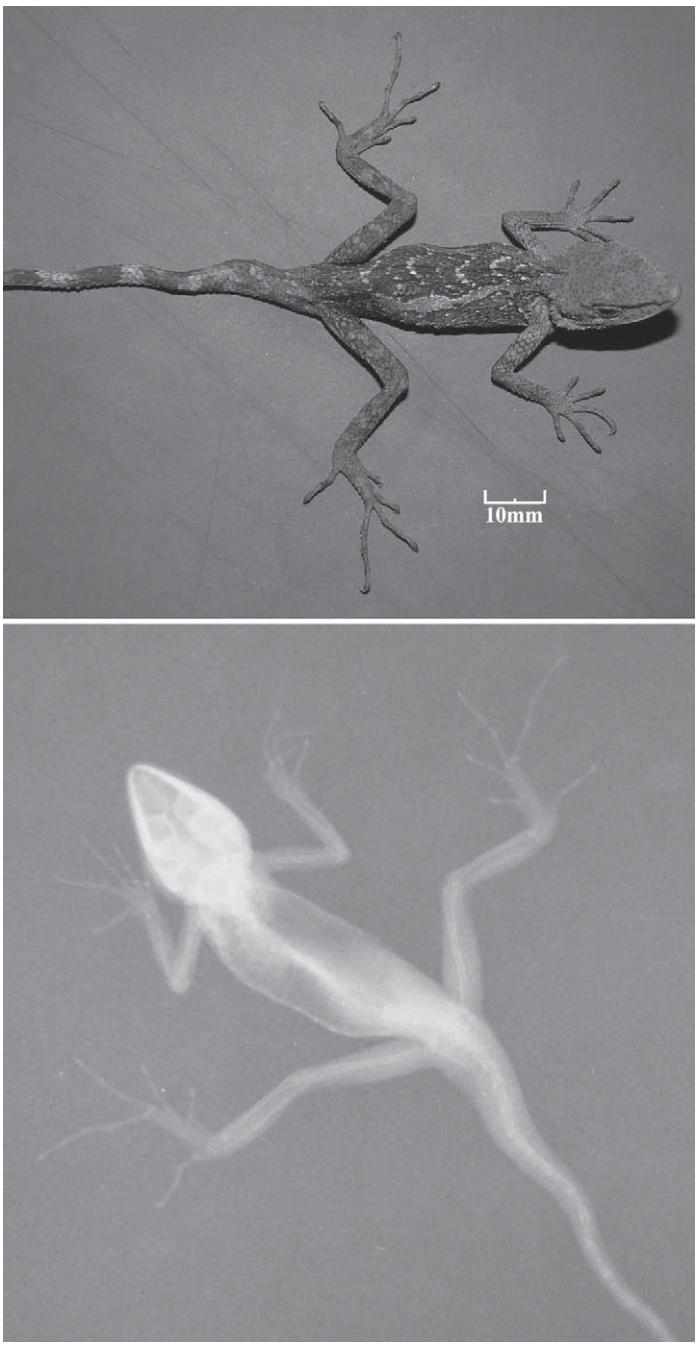

FIG. 1. The dorsal view (top), and radiograph (bottom) of the Swinhoe's Tree Lizard (*Japalura swinhonis*), illustrating the deformed spine.

159 mm, and 6.9 g, respectively. A radiograph was taken, but we observed no fractures or other abnormalities (Fig. 1). The common symptoms of osteodystrophy—fractured limbs or hindlimb paresis, swollen limbs and digits, swollen mandibles, dull coloration, anorexia and lethargy, and/or hypocalcaemic tetany and seizures (O'Malley 2007. Irish Vet. J. 60:303–309)—were not observed, and the lizard appeared healthy. After flushing its stomach for internal parasites, the animal was maintained in captivity for a month, and was then released back into the wild at the same location where it was collected. During the period of captivity, the condition of the lizard did not visibly deteriorate or improve, and since the animal was free-living, we believe that this condition is due to a sub-lethal genetic defect. To our knowledge, this appears to be the first reported instance of such a condition in *J. swinhonis* in the wild.

KENTROPYX VANZOI (NCN). **ENDOPARASITES.** The poorly known teiid *Kentropyx vanzoi* is a medium-sized lizard that inhabits open habitats along river systems in central Brazil (Gallagher and Dixon 1980. Copeia 1980:616–620). To the best of our knowledge no reports on endoparasites have been published for this species. Herein, we provide information on helminth parasites of *K. vanzoi* from two localities of Mato Grosso state, Central Brazil.

Three *K. vanzoi* specimens were examined for endoparasites from the Coleção Zoológica de Vertebrados da Universidade Federal de Mato Grosso. The lizards were collected from two localities dominated by Cerrado (savanna-like vegetation) in the Mato Grosso state in the municipality of São José do Rio Claro (13.8122°S, 56.6900°W; datum: SAD69); and in the municipality of Primavera do Leste (15.2267°S, 54.0469°W; datum SAD69). The specimen (UFMT 398) from São José do Rio Claro was an adult female collected from a pit-fall trap on 27 May 2001. The specimens (UFMT 1757, 1758) from Primavera do Leste were an adult female and an adult male, respectively, also collected from pitfall traps between 10–14 July 2008. We opened and separately examined the specimens for helminths in the body cavity, esophagus, stomach, lungs, and small and large intestines under a stereomicroscope. Helminths were cleared in phenol, identified, and deposited in the Coleção Helmintológica do Instituto de Biociências da Unesp de Botucatu. The nematode *Physalopteroides venancioi* was found in the body cavity of the female specimen from São José do Rio Claro. Larvae of the cestode *Oochoristica* sp. were recovered from the body cavity and two females of the nematode *Parapharyngodon senisfaciecaudus* were recovered from the large intestine of the female specimen from Primavera do Leste. The male specimen from Primavera do Leste was uninfected.

Reports on endoparasites from *Kentropyx* species in Brazil are scarce and restricted to *K. calcarata*, and include *Kentropyxia sauria* (Baker 1982. Proc. Helminthol. Soc. Washington 49:252–257; Goldberg et al. 2007. Comp. Parasitol. 74:327–342), *Oswaldocruzia* sp. (Ávila and Silva 2009. J. Helminthol. 83:267–269), *Piratuba shawi* (Vicente et al. 1993. Rev. Bras. Zool. 10:19–168), *P. digiticauda* (Ávila and Silva, *op. cit.*), *Physalopteroides venancioi* (Ávila and Silva, *op. cit.*), and *Physaloptera retusa* (Ávila and Silva, *op. cit.*; Goldberg et al., *op. cit.*). Thus, *K. vanzoi* represents a new host record for *Oochoristica* sp., *P. senisfaciecaudus*, and *P. venancioi*. To the best of our knowledge, Brazil represents a new country record for *P. senisfaciecaudus* and Mato Grosso state represents a new locality record for *Parapharyngodon senisfaciecaudus*.

LEIOSAURUS CATAMARCENSIS (NCN). **CLUTCH SIZE**. *Leiosaurus catamarcensis* is an inhabitant of the Monte phytogeographical province (Cei. 1993. Mus. Reg. Sci. Nat. Torino Monogr. 14:1–949). The biology of this species is poorly known. Blanco and Acosta (2003. Herpetol. Rev. 34:145) reported on clutch size for one female of this species, observing 10 eggs. Villavicencio et al. (2006. Actas de Congreso Argentino de Herpetología, Corrientes. 15 pp.), established the thermal parameters for this species. In this note we report the clutch size for one lizard under laboratory conditions in order to contribute to the limited knowledge of this species' reproductive biology.

During December 2008, a basking female *L. catamarcensis* (84 mm SVL, 21 g) was hand-captured in the field at 0930 h, in San Juan Province, Calingasta Department, on Nacional Route Nº 149 (31.14°S, 69.01°W; datum WGS 84, elev. 2500 m).

Six days after capture on 11 December 2008, this lizard laid a clutch of seven eggs in the laboratory (25ºC and 30% relative humidity). Total egg mass was 6 g, 28.5% of the female mass. Mean egg length was 17.67 ± 0.53 mm and mean egg width was 10.97 ± 0.45 mm. Mean egg volume was estimated (114.5 ± 7.07 mm^3), using the equation [V= 4/3π (L/2) $(W/2)^2$] for an elliptical sphere (Dunham 1983. *In* Huey et al. [eds.], Lizard Ecology, pp. 261–280. Harvard University Press, Cambridge, Massachusetts). To our knowledge, this is the second report of clutch size for this species.

PHRYNOSOMA BRACONNIERI (Short-tailed Horned Lizard). **DEFENSIVE BLOOD-SQUIRTING BEHAVIOR.** On 6 June 2007, one of us (CR) picked up an adult *Phrynosoma braconnieri* (sex unknown) at 1400 h in hills 8.0 km NW of Cacaloapan, Municipio de Tepanco de López, Puebla, México. The lizard was carried by hand up the trail a short way until it was realized that it had ejected blood from its right eye. Blood on the lizard's eyelids, face, and lower jaw was photographed. It may have been the result of a single or a few squirts. There were no canids in the field with the collector. Six other encounters (CR) involving hand collection of the same species failed to elicit blood-squirting behavior: (N = 1) 5.3 k further west of Cacaloapan (later the same day; 1600 h); (N = 1) at (San Juan Bautista) Cuicatlan, Oaxaca, México (17 June 2006); and (N = 4) at Rancho Tejas (near Ixtlan de Juarez), Oaxaca, México (27 September 2009). All animals were of subadult to adult size (sexes 0.2.2). Similar encounters with *P. braconnieri* (N = 5) in Puebla, México, in 2003 all failed to elicit blood-squirting during hand-capture by humans (Sherbrooke and Mendoza-Quijano 2005. Herpetol. Rev. 36:65–66). Combining our similar encounters (human capture-by-hand), 8% (1 of 12) of the lizards squirted blood.

In the first recognition of the possibility of differences in the occurrence of anti-predator blood-squirting responses between living species of horned lizards (*Phrynosoma* spp.) Sherbrooke and Middendorf (2001. Copeia 2001:1114–1122) predicted, based on purported phylogenetic relationships, that *P. braconnieri* would be determined to be a species utilizing a blood-squirting defense. That prediction was based solely on *P. braconnieri* being a sister taxon of *P. taurus*, a species previously reported to be capable of blood-squirting (Ruthling 1919. Copeia [72]:67–68). Subsequently, following reevaluation of the occurrence of blood-squirting in *P. taurus* that involved both field collection by humans and canid (dog-bioassay) trials, the earlier report (Ruthling 1919, *op. cit.*) of blood-squirting by *P. taurus* was questioned (Sherbrooke et al. 2004. Herpetol. Rev. 35:345–347). With that apparent reversal of designation of *P. taurus* (from a blood-squirting to an apparent non-blood-squirting species) it was suggested that *P. braconnieri* might also have lost its defensive blood-squirting. This attribute appears to be plesiomorphic in the genus (Sherbrooke and Middendorf 2001, *op. cit.*; Leaché and McGuire 2006. Mol. Phylogen. Evol. 39:628–644). The conclusion that *P. braconnieri* may have lost its blood-squirting defense was further supported by negative results during limited dog-bioassay trials (Sherbrooke and Mendoza-Quijano 2005. Herpetol. Rev. 36:66–67). It had also been noted that the earlier prediction that *P. braconnieri* might be a blood-squirting species (Sherbrooke and Middendorf 2001, *op. cit.*), based on its sister-taxon relationship with *P. taurus*, was premature. In addition, Hodges (2004. Southwest. Nat. 49:267–270) reported no blood squirting in response to human hand-capture of *P. braconnieri* (N = 6) and *P. taurus* (N = 20). The negative results, from field encounters by humans and from dog-bioassay trials, and the apparent reversal in status of *P. taurus* did not fully resolve the blood-squirting status of *P. braconnieri*. Confounding factors such as the occurrence of eyelid puffiness during dog trials (a precondition to blood ejection; Middendorf and Sherbrooke 1992. Copeia 1992:519–527) and the inherent difficulty in establishing negative conclusions from negative results remained.

Shortly thereafter a field report of an apparent single squirt of blood during human hand-capture of a *P. taurus* (Garcia-Vazquez and Canseco-Marquez 2006. Herpetol. Rev. 37:347) brought into question the earlier suggestion that *P. taurus*, and, by implication, possibly *P. braconnieri* were non-blood-squirting species (Sherbrooke et al. 2004, *op. cit.*). In a similar apparent "reversal" in evaluation of blood-squirting status for a species (see discussion below), we here report the first evidence of a blood-squirting response (to human handling) by *P. braconnieri*, the other member of its sister-taxon pair *braconnieri-taurus*.

This report leaves unresolved questions surrounding the natural conditions under which a horned lizard's defense of squirting blood from ocular blood-sinuses may be employed by *P. braconnieri*, with canids or other predators (Middendorf and Sherbrooke 1992, *op. cit.*; Sherbrooke and Mason 2005. Southwest. Nat. 50:216–222; Sherbrooke and Middendorf 2004. Copeia 2004:652–658). In addition, our report, with that of Garcia-Vazquez and Canseco-Marquez (2006, *op. cit.*) for *P. taurus*, suggests the need for cau-

tious revisions to interpretations of the phylogenetic history of blood-squirting presented by Sherbrooke and Middendorf (2001, *op. cit.*) and by Leaché and McGuire (2006, *op. cit.*). The *braconnieri-taurus* lineage can probably no longer be considered as one in which blood-squirting has been "lost," certainly not completely. Can such decisions regarding evolutionary trends/changes in a species be based on a one-time observation of a single individual? The frequency of occurrence, effectiveness, and taxonomic range (of target predators) (natural: coyotes, foxes, etc.; unnatural: humans) of horned lizards utilizing this defense remain largely unknown (but see Middendorf and Sherbrooke 1992, *op. cit.*; Sherbrooke and Middendorf 2001, 2004, *op. cit.*). And, in both cases, the "reversals" in blood-squirting status of *P. braconnieri* and *P. taurus* are based on single observations with humans. Under stress of capture by a human other lizards may rarely exhibit ocular bleeding (*Sceloporus jarrovii* and *Urosaurus ornatus*, Sherbrooke 2000. Herpetol. Rev. 31:243; *Sceloporus occidentalis* Klauber 1939. Bull. Zool. Soc. San Diego 14:80–100, and J. Shedd, pers. comm.).

Without the presentation of a proper stimulus or stimuli, and other possibly unknown conditions, we should not expect to elicit a defensive blood-squirting response from a horned lizard even if it is capable of the response. One species, *P. ditmarsi*, was evaluated in two series of dog-bioassay trials before it was shown to squirt ocular-sinus blood (Sherbrooke and Middendorf 2001, *op. cit.*; Hodges 2004, *op. cit.*).

The history of evaluations of *P. braconnieri* and *P. taurus* as blood-squirting or non-blood-squirting serves as a cautionary tale for those trying to come to conclusions regarding the occurrence, presence or absence, of blood-squirting in species of horned lizards. Note should be made that the "nonblood-squirting" designation used by Sherbrooke and Middendorf (2001, *op. cit.*) called attention to the low frequency of blood squirting (relative to *P. cornutum*, *P. hernandesi*, and *P. solare*) within the clade *mcallii-modestum-platyrhinos* of horned lizards, not to its complete absence (two of the three species within this clade were reported to have squirted blood on rare occasions). Without knowing more about the frequency of occurrence of blood squirting within and between geographic populations of a species and under a broader array of potential predator-prey encounters, it remains difficult to conclude that a species has lost blood squirting as a defense, even if it has never been recorded. Conclusions based solely on an absence or reduced frequency of blood-squirting during limited field encounters with humans (probably not representative of evolutionarily determined predator-threat stimuli) and on dog-canid trials (as in the cases of *mcallii-modestum-platyrhinos* and *braconnieri-taurus*) may be suggestive of evolutionary trends but may also lead to confusion. This could be due to their limited scope and subtleties in the nature of the evolved role(s) of blood-squirting in horned lizard species. Lower frequencies of occurrence in some species may be influenced by lack of appropriate elicitation stimuli (type of predator), the physiological condition of lizards, or factors such as individual, population or species dietary history (types and predominance of ants; a potential source of anti-predator chemical compounds [Sherbrooke and Middendorf 2004, *op. cit.*; Sherbrooke and B. A. Kimball, unpubl. data]).

Thus, we are left with questions; are species of horned lizards in which blood squirting remains unreported (*P. douglassi* and *P. mcallii*; also *P. coronatum*, *P. cerroense*, *P. wigginsi*, *sensu* Montanucci 2004. Herpetologica 60:117–139, and Leaché et al. 2009. PNAS 106:12418–12423) or has been reported at low frequencies to humans and canids (*P. braconnieri*, *P. goodei*, *P. modestum*, *P. platyrhinos*, *P. taurus*) "non-blood squirting" species? Are these species in some stage of losing the defense, or is their apparent "non-blood squirting" designation the result of our own restricted insights into its frequency and distribution of occurrence under varied conditions in nature? We hope that awareness of these issues can help us formulate and test hypotheses that may lead to a better understanding of this fascinating defense.

Submitted by **WADE C. SHERBROOKE,** Southwestern Research Station, American Museum of Natural History, P.O. Box 16553, Portal, Arizona 85632, USA (e-mail: wcs@amnh.org); and **CHRIS RODRIGUEZ**, SOCAL Bio-Environmental Associates, 1276 N. Deborah Avenue, Azusa, California 91702, USA (e-mail: sleepingbird@aol.com).

PHRYNOSOMA HERNANDESI (Greater Short-horned Lizard). **PREDATION**. Although arthropods are well known predators of vertebrates (review in McCormick and Polis 1982. Biol. Rev. 57:29–58), the impact of arthropod predation on lizards has received little attention (Vitt 2000. Herpetol. Monogr. 14:388–400). Among arthropods, spiders are often reported to prey on vertebrates, especially anurans (review in Toledo 2005. Herpetol. Rev. 36:395–400), although they infrequently include lizards (Cokendolpher 1977. J. Arachnol. 5[2]:184; Corey 1988. J. Arachnol. 16[3]:391–392). Blondheim and Werner (1989. Brit. Herpetol. Soc. Bull. London 30:26–27) reported the lacertid lizard, *Mesalina guttulata*, predated by the widow spiders (*Latrodectus pallidus* and *L. revivensis;* Theridiidae), Schwammer and Baurecht (1988. Herpetozoa, Wien 1[1/2]:73–76) reported the lacertid, *Podarcis melisellensis*, as prey of the widow spider (*L. mactans*), and Hodar and Sanchez-Piñero (2002. J. Zool. Lond. 257:101–109) reported the lacertids, *Acanthodactylus erythrurus*, *Psammodromus hispanicus*, and *P. algirus*, and the gekkonid, *Tarentola mauritanica* as prey of the widow spider, *L. lilianae*. Large arthropods incapable of capturing adult lizards are likely significant predators of neonatal lizards, especially those < 50 mm SVL (Vitt 2000, *op cit.*).

On 21 July 2009 one of us (LKK) discovered a subadult female Western Black Widow Spider (*Latrodectus hesperus*; ca. 9 mm body length) that had completely ensnared a neonate *Phyrnosoma hernandesi* (SVL 21 mm; TL 9 mm) that was caught in a large funnel trap set for terrestrial snakes in grassland habitat. The observation occurred in New Mexico, Bernalillo County, Albuquerque, Kirtland Air Force Base, USA. The *P. hernandesi* was dead and was being attended by the Black Widow as if feeding on the lizard. Both were collected and are deposited in the Museum of Southwestern Biology Division of Arthropods (*L. hesperus* MSBA 23492) and Division of Herpetology (*P. hernandesi* MSB 76339). To our knowledge this is the first report of *P. hernandesi* being preyed upon by the Western Black Widow Spider.

Submitted by **CHARLES W. PAINTER**, New Mexico Dept. Game and Fish, 1 Wildlife Way, Santa Fe, New Mexico 87507, USA (e-mail: charles.painter@state.nm.us); and **LARRY K. KAMEES**, Keystone Ecological Services, 99 Ranchitos Road Sandia Park, New Mexico 87047, USA (e-mail: lkamees@yahoo.com).

PHRYNOSOMA MODESTUM (Round-tailed Horned Lizard). **BLOOD-SQUIRTING**. *Phrynosoma modestum* was heretofore thought to be a member of a "non-blood-squirting" clade including *P. mcallii* and *P. platyrhinos* (Sherbrooke and Middendorf III. 2001. Copeia 2001:1114–1122). Here we report blood-squirting by *P. modestum*.

At 1530 h on 14 August 2009 we collected an adult male (50 mm SVL, 6.4 g) Round-tailed Horned Lizard (*Phrynosoma modestum*) ca. 7 km SE of Fowler in Otero County, southeastern Colorado, USA. When first captured, the specimen squirmed and ultimately wriggled out of DW's hand. The animal darted several meters while evading capture, and was subsequently pinned to the ground with more pressure than normal to prevent a second escape. At this time the specimen squirted a small amount of blood (ca. 0.025 ml) from an ocular sinus of the right eye. Blood was also visible surrounding the right eye, which was still swollen and engorged a few moments following the blood-squirting event when photos were taken (Fig. 1A). While photographing this individual at close range (<1 m) following its release, DM noted rapid swelling and subsequent rapid dissipation of swelling of the upper and lower lids around the left eye (Fig. 1B–1D). It is presumed that the lizard was preparing to squirt blood again, this time from the other eye, but found it unnecessary.

Blood-squirting is thought to be primarily a defense against predation attempts by canids (Middendorf and Sherbrooke 1992. Copeia 1992:519–527); potential canid predators in the area include Coyotes (*Canis latrans*), Domestic Dog (*C. lupus familiaris*), and Swift Fox (*Vulpes velox*), but can also be elicited by human contact (Hodges 2004. Southwest. Nat. 49:267–270). To our knowledge this is the first substantiated incidence of *P. modestum* squirting blood (confirmed by W. Sherbrooke, pers. comm.). Field work was conducted under Colorado Division of Wildlife scientific collection license 09HP927 and with permission of the landowner.

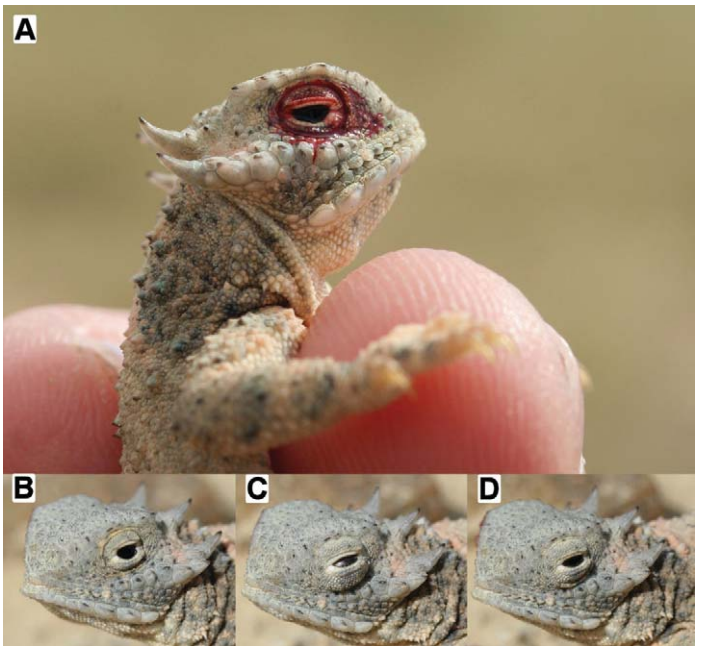

FIG. 1. A) Adult male *Phrynosoma modestum* after squirting blood from the ocular sinus of the right eye. B–D) The same individual after release at 15:43 h, apparently preparing to squirt blood from the left eye, demonstrating the lizards eye before swelling (B, 15:44:55 h), during swelling (C, 15:45:07 h), and after dissipation of swelling (D, 15:45:10 h). Photographed in the field in Otero County, Colorado, 14 August 2009.

PLESTIODON FASCIATUS (Five-lined Skink). **PREDATION**. Few reports document spider predation on small squamates, and most involve larger spiders, i.e. wolf spiders or orb weavers. Cokendolpher (1977. J. Arachnol. 5:184) observed an orb weaver (*Argiope aurantia*) eating a Broad-headed Skink (*Plestiodon laticeps*); Corey (1988. J. Arachnol. 16:392–393) observed a wolf spider (*Lycosa ammophila*) feeding on a Green Anole (*Anolis carolinensis*); and Hampton et al. (2004. Herpetol. Rev. 35:269–270) observed a wolf spider (*Hogna carolinensis*) feeding on a Ground Skink (*Scincella lateralis*). To our knowledge, no prior records exist of predation of lizards by cobweb spiders (Family Theridiidae), a family of spiders with relatively small body sizes (cephalothorax length range: 1–8 mm; Craig 1987. Am. Nat. 129:47–68). Here we provide an observation of predation by an American House Spider, *Achaearanea tepidariorum,* on a juvenile *Plestiodon fasciatus*.

At ca. 1000 h on 11 August 2006, we observed an *A. tepidariorum* with its fangs deployed in a juvenile (36.0 mm SVL) *P. fasciatus* inside a building at the Tennessee Aquarium Conservation Institute at Cohutta Springs, ca. 1.2 km S of Red Clay, Georgia (34.9739°N, 84.9503°W; datum: WGS84, elev. 259 m). The skink was near death and struggling listlessly. After photographing the scene, we preserved both the spider and the skink. The skink had lost a portion of its tail. As the spider appeared to be actively feeding on the skink at the time of capture, we discount the possibility that the spider was merely investigating a disturbance in its web.

Specimens are deposited in the California Academy of Sciences collections (*Plestiodon*, CAS 235426; *Achaearanea*, CASENT 9024310). We thank J. Miller and J. Vindum for confirming identifications and accessioning the specimens.

NEELY**, California Academy of Sciences, 55 Music Concourse Drive, Golden Gate Park, San Francisco, California 94118, USA (e-mail: dave.neely@gmail.com).

PODARCIS MURALIS (Common Wall Lizard). **CONTROL.** *Podarcis muralis* is a medium-sized European lizard that has been introduced into at least three states/provinces (Ohio, Kentucky, and British Columbia; Burke and Deichsel 2008. *In* Jung and Mitchell [eds.], Urban Herpetology, pp. 347–353. Herpetol. Conserv., Vol. 3, SSAR). Walker and Deichsel (2005. Herpetol. Rev. 36:202) report

the discovery of this exotic species at The Falls of the Ohio State Park, Indiana. Werner Mayer (Museum of Natural History, Vienna, Austria) determined the subspecies as *Podarcis muralis maculiventris*, western clade based on mtDNA sequences. This form is identical to that of specimens observed within Cincinnati, Ohio for over 50 years now. Here we report on measures of controlling this alien species in Indiana and its impact on a native one.

Concerns regarding the presence of *Podarcis muralis* in Indiana resulted in the Indiana Department of Natural Resources (IDNR) enacting an executive order to control this species. The executive order was designed to address two concerns regarding the presence of this species. The first concern was that *Podarcis muralis* might displace native Five-lined Skinks (*Plestiodon fasciatus*) where both species are sympatric. The second concern was to act quickly before the lizards became established and spread to adjacent habitats. The control program was first conducted from 7 July to 15 August 2005 by Nick Burgmeier, and subsequently by two contractors in 2006 and 2007. A total of ca. 30 *P. muralis* were removed from the park and euthanized, most of which were discarded. Two specimens were deposited at the Purdue University Biology collection in West Lafayette, Indiana (25.021, 25.022). One specimen from the Falls of the Ohio State Park is in the Field Museum collection (FM 265504).

The control program was accompanied by visual surveys inside and outside the State Park. As sightings of *Podarcis* decreased, there were increased observations of *P. fasciatus.* However, there were fewer *Podarcis* observed and subsequently captured than predicted. This might be attributed to the flooding of the Falls of the Ohio State Park during the winter of 2004–2005. During this time, the riprap below the interpretative center's observation deck (the focus of *Podarcis* occurrence) was submerged. This flood event possibly drowned many of the *Podarcis* hibernating there. Additionally, local predators might have helped to reduce the *Podarcis* population. Feral Cats (*Felis silvestris catus*) and Mockingbirds (*Mimus polyglottos*) were seen preying upon *Podarcis* within the state park.

After control programs were concluded, GD inspected the area from 11–13 October 2007. Surveys were performed under excellent weather conditions but no *Podarcis* were observed. However, two *P. fasciatus* were seen during this same time period. In the summer of 2008, park personnel and visitors reported additional sightings of juvenile and adult *P. muralis* as well as several *P. fasciatus* (Sarabeth Klueh, pers. comm.). During 2009, park personnel reported only sightings of *P. fasciatus*, but no sightings of *Podarcis* as of 18 September (Bett Etenohan, pers. comm.)

We conclude that the return of *P. fasciatus* after *Podarcis* removal is a good indication that the exotic species likely has had a negative impact on natives. However, the quick recovery of the *Podarcis* population during 2008 might indicate that there is a flow of lizards into the park from illegal release and/or from rafting on driftwood originating from places upriver from Clarksville and as far as Cincinnati. We suggest that the population dynamics of both species be further observed. We would further recommend that land managers take appropriate measures to control the introduced species as necessary.

Submitted by **GUNTRAM DEICHSEL**, Friedrich-Ebert-Str. 62, Biberach, Germany DE-88400 (e-mail: Guntram.Deichsel@gmx.de); and **ZACHARY WALKER**, Wyoming Game and Fish Department, 3030 Energy Lane, Casper, Wyoming 82604, USA (e-mail: Zack.Walker@wgf.state.wy.us).

SCELOPORUS SPINOSUS SPINOSUS (Spiny Lizard). **BROOD**. *Sceloporus spinosus* is distributed along the central plateau of Mexico. Three subspecies are recognized: *spinosus* is the most widely distributed, while two others—*apicalis* and *caeruleopunctatus*—are endemic to the state of Oaxaca (Bell et al. 2003. Acta Zool. Mex. [n.s.] 90:103–174; Sites et al. 1992. Bull. Am. Mus. of Natl. Hist. 213:1–110; Smith 1939. Zool. Ser. Field Mus. Nat. Hist. 26:59–172; Smith and Taylor 1950. U.S. Natl. Mus. Bull. 199:1–253). Here we report record egg size and dimensions for the species and incubating time under laboratory conditions.

Mean size of sexually mature females varies among populations (69–106 mm SVL), courtship occurs in early spring, and eggs are laid mainly during middle or late summer (Calderón-Espinosa et al. 2006. Herpetol. Monogr. 20:47–158). Females of some populations lay a single clutch per season while females in other populations may lay more than one (Castro-Franco 2002. M.Sc. dissertation, Facultad de Ciencias, Universidad Nacional Autónoma de México; Valdéz-Gonzáles and Ramírez-Bautista 2002. J. Herpetol. 36:36–43). Oviposition is asynchronous within populations as females at all stages of gravidity are found at any one time during the reproductive season (Calderón-Espinosa. et al. 2006, *op. cit*).

On 23 June 2007, a gravid female *S. spinosus spinosus* was obtained from Los Reyes La Paz, Estado de Mexico, Mexico, (19.3543°N, 98.9403°W, 2633 m elev.), and brought into the laboratory and assigned collection number 4401-E. The lizard weighed 50.55 g before oviposition, and was maintained in a plastic box measuring 32 × 20 × 14 cm, with newspaper as substrate, fresh water in a dish, and ambient temperature at 26–28ºC.

On the morning of 4 July 2007, the female laid a clutch of 13 eggs (female weighed 35.74 g post-oviposition), which were placed in plastic boxes with agrolite substrate. An incubator was used to provide a 28–30ºC thermal gradient and relative humidity fluctuated between 50–70%. Mean measurements of the eggs were as follows: length 16.2 ± 01.5 mm and width 10.8 ± 00.7 mm, mean mass 1.13 ± 0.12 g.

Four hatchlings emerged on 28 August 2008 and the remaining nine the next day. The mean incubation time was 55.5 ± 0.5 days at 28–30ºC. Mean measurements were as follows: 27.6 ± 01.7 mm SVL, 34.1 ± 01.2 mm tail length and the neonates weighed 0.86 ± 0.03 g. Hernández-Ibarra et al. (2001. XVI Congreso de Zoología, Memorias, Zacatecas, p. 43) reported that this species lays clutches ranging from 10 to 30 eggs, and Valdez-González (1998. Graduate dissertation, Facultad de Estudios Superiores Iztacala, Universidad Nacional Autónoma de México) reported clutch numbers of 15.3 ± 1.2 eggs; mean measurements of the eggs were as follows: length 15.1± 0.65 mm and width 8.8 ± 0.3 mm, with mean weight of 1.69 ± 0.808 g.

TRACHYLEPIS PLANIFRONS (Tree Skink). **REPRODUCTION.** *Trachylepis planifrons* is known from Kenya, Tanzania, Somalia, eastern Ethiopia, northern Zambia, and southeastern Democratic Republic of Congo (Spawls et al. 2002. A Field Guide to the Reptiles of East Africa, Kenya, Tanzania, Uganda, Rwanda and Burundi. Academic Press, San Diego, California. 543 pp.). Other than a report that *T. planifrons* is oviparous (Spawls et al., *op. cit.*), I know of no information on the reproduction of this species. The purpose of this note is to report information on the reproduction of Kenya *T. planifrons* from a histological examination of gonadal material.

A sample of 11 *T. planifrons* consisting of four adult males (mean SVL = 87.0 mm ± 14.0 SD; range: 70–90 mm) and seven adult females (mean SVL = 98.4 mm ± 5.4 SD; range: 90–104 mm) collected 1971 or 1973 were examined from the herpetology collection of the Natural History Museum of Los Angeles County (LACM), Los Angeles, California (by Kenya District): Lamu: LACM 93191–93196; Samburu: 65770–65772, 65899, 65902. The left testis was removed from males and the left ovary was removed from females for histological examination. Tissues were embedded in paraffin and cut into sections at 5 μm. Slides were stained with Harris hematoxylin followed by eosin counterstain. Slides of testes were examined to determine the stage of the spermatogenic cycle. Slides of ovaries were examined for the presence of yolk deposition. Histology slides are deposited in LACM.

The only stage noted in the testicular cycle was spermiogenesis (= sperm formation) in which the seminiferous tubules are lined by clusters of sperm or metamorphosing spermatids. Spermiogenesis was noted in one male from February and three from June. The smallest reproductively active male (spermiogenesis in progress) measured 70 mm SVL (LACM 65772) and was from June. Ovaries were classified (sample size in parentheses) as to their reproductive state: quiescent (no yolk deposition): February (1); early yolk deposition (yolk granules in the cytoplasm): February (2), June-July (1); oviductal eggs: February (2), 8 and 9 oviductal eggs, respectively; corpora lutea: June-July (1). Eight and nine eggs are the first clutch sizes reported for *T. planifrons*. The smallest reproductively active female (corpora lutea present) measured 90 mm SVL (LACM 65902) and was from June–July. The presence of reproductive activity in February and June-July suggests *T. planifrons* exhibits a prolonged period of reproduction.

I thank Christine Thacker (LACM) for permission to examine specimens.

Submitted by **STEPHEN R. GOLDBERG,** Department of Biology, Whittier College, Whittier, California 90608, USA; e-mail: sgoldberg@whittier.edu.

TRACHYLEPIS SULCATA (Western Rock Skink). **REPRODUCTION.** *Trachylepis sulcata* is viviparous and occurs from karroid areas of the Cape and adjacent Free State of the Republic of South Africa through Namibia to southern Angola (Branch 1998. Field Guide to Snakes and Other Reptiles of Southern Africa. Ralph Curtis Books, Sanibel Island, Florida. 399 pp.). Information on its reproduction in the Republic of South Africa was summarized by Bates (1995. Afr. Herp News 24:23–25). The purpose of this note is to compare information on *T. sulcata* reproduction from the Republic of South Africa with data from Namibia taken from a histological examination of museum specimens.

A sample of eight females from Namibia collected in 1972, 1976, 1977 (mean SVL = 64.3 mm ± 8.4 SD, range: 57–83 mm) was examined from the herpetology collection of the Natural History Museum of Los Angeles County (LACM), Los Angeles, California USA. Specimens examined by the Namibia region are: Erongo LACM 127496, 127497; Karas LACM 77017; Khomas LACM 77432, 77433, 77435, 77437, 77439. For histological examination the left ovary was removed from females to check for vitellogenesis (yolk deposition). Counts were made of oviductal eggs/embryos or enlarged ovarian follicles (> 5 mm length). Tissues were embedded in paraffin, sections cut at 5 μm, and stained with Harris hematoxylin followed by eosin counterstain. Histology slides are deposited in LACM.

One October female (LACM 77437) contained corpora lutea from a previous litter and concomitant yolk deposition for a subsequent litter verifying *M. sulcata* may produce multiple litters in the same reproductive season as stated by Bates (*op. cit*) and Branch (*op. cit.*). Mean litter size for four females was 3.5 ± 2.4 SD, range: 2–7. Seven embryos is a new maximum litter size for *T. sulcata* and was recorded from LACM 127497, collected in May. It is not known when these embryos would have completed development. Another October female of the same size (LACM 77433) had quiescent ovaries (no yolk deposition). It was not possible to count litter sizes for two females from October with enlarged follicles that had been shot (LACM 77017, 77439). The smallest reproductively active female from Namibia (enlarged follicles > 5 mm) measured 57 mm (LACM 77439) and was from October. In contrast, Bates (1995, *op. cit*.) reported the smallest reproductively active female *T. sulcata* from the Free State Province of South Africa to measure 63 mm SVL and that parturition occurred from November to March. The presence of two October females from Namibia reported herein, one with two full-term embryos (LACM 77432) and one with corpora lutea (LACM 77437) from a previous litter October suggests there may be geographic variation in the ovarian cycle of *T. sulcata*.

I thank Christine Thacker (LACM) for permission to examine *T. sulcata.*

Submitted by **STEPHEN R. GOLDBERG,** Whittier College, Department of Biology, PO Box 634, Whittier, California USA; e-mail: sgoldberg@whittier.edu.

TROPIDURUS ITAMBERE (Rock Lizard). **HAEMOPARASITES.** *Plasmodium* (*Sauramoeba*) *tropiduri* (Apicomplexa: Plasmodiidae) is a malaria parasite that can infect lizards of the genus *Tropidurus*. This parasite was described by Aragão and Neiva (1909. Mem. Inst. Oswaldo Cruz 1:44–50) in individuals of *T. torquatus* from Minas Gerais state, southeastern Brazil. Carini (1941. Arq. Biol. São Paulo 235:46–47) subsequently reported it in *T. torquatus* from Goiás state, central Brazil. Later, its presence was reported in *Tropidurus* species from other Brazilian states (Pessoa and Souza Lopes 1963. Inst. Med. Trop. São Paulo 5:133–139; Rocha-Silva and Rodrigues 1974. Rev. Saúde. Publ. São Paulo 8:163–170) and from Venezuela (Scorza 1971. J. Protozool. 18:403–410). During our literature review, we could not find any reports of *P. tropiduri* infecting *Tropidurus* lizards after the 1970s. Considering that the taxonomy of this genus was later

revised (Rodrigues 1987. Arq. Zool. São Paulo 31:105–230; Frost et al 2001. Mol. Phylogenet**.** Evol. 21:352–371) and consequently new species were described, one of which was *Tropidurus itambere*, new studies regarding the presence of this haemoparasite in the *Tropidurus* genus are important.

Herein, we provide the first report of *Plasmodium* (*Sauramoeba*) *tropiduri* in the blood of the lizard *Tropidurus itambere*. It is a medium-sized lizard (mean adult SVL = 71.8 mm) (Rodrigues 1987, *op. cit*.) belonging to the *torquatus* group (Frost et al. 2001, *op. cit*.). It commonly occurs in open, and sometimes rocky, areas in central and southeastern Brazil (Rodrigues 1987, *op. cit*.).

This study was accomplished with 12 adult individuals of *T. itambere* (eight males and four females) collected in a rocky outcrop area located at Ibitipoca State Park (21.696667°S, 43.889167°W; elev. 1200 m), Minas Gerais state, southeastern Brazil, between February and May 2007. We made sanguine smears of collected circulating blood from the abdominal vein of the lizards. The parasitemia was calculated through the number of parasites found in 100 homogeneous microscopic fields of each sanguine smear (parasite density), and the value found was multiplied by 100 and divided by 10.000 (×*100/10.000).

We identified the parasite *P. tropiduri*, with a low parasitemia (mean = 0.16%), in three lizards (two females and one male) of the 12 examined. The low parasitemia of this lizard species was also reported by other authors (Carini 1941, *op. cit*.; Laison and Shaw 1969. Parasitology 59:163–170; Rocha-Silva and Rodrigues 1974, *op. cit*.). The diagnosis of *P. tropiduri* was based on the following characters: all the intraerythrocytic stadia (trophozoites, schizonts, and gametocytes) were identified and usually located in the polar or lateropolar region of the erythrocyte (host cell); rounded gametocytes; schizonts with about 18 merozoites; hypertrophied and lightly deformed erythrocytes.

The morphological analysis of the intraerythrocytic stadia of *P. tropiduri* revealed circular, rounded, prolonged, and ellipsoidal forms. The same was reported by Aragão and Neiva (1909, *op. cit*.), Carini (1941, *op. cit*.), Gahram (1966. Malaria Parasites and Other Heamosporidia. Blackwell Scientific Publications, Oxford. 1114 pp.), Laison and Shaw (1969, *op. cit*.) and Rocha-Silva and Rodrigues (1974, *op. cit*.).

The lizard specimens are deposited in the herpetology collection of the Department of Zoology of the Federal University of Juiz de Fora (numbers: 466, 467, 489, 491, 506–508, 515–517, 614, 618).

We thank CAPES for financial support and the Commission of Ethics in Animal Experimentation from the Research Rectory of Federal University of Juiz de Fora, IBAMA and the IEF of Minas Gerais for the permission to undertake this study.

Submitted by **JULIANA VAZ E NUNES** (e-mail: juvazenunes@yahoo.com.br), **BERNADETE MARIA DE SOUSA** (e-mail: bernadete.sousa@ufjf.edu.br), **THIAGO ELISEI** (e-mail: thiagoelisei@yahoo.com.br), Programa de Pós-graduação em Ciências Biológicas – Comportamento e Biologia Animal, Universidade Federal de Juiz de Fora, Campus Universitário Martelos, CEP 36.036-900, Juiz de Fora, Minas Gerais, Brazil; and **CARINA ELISEI** (e-mail: carinaelisei@yahoo.com.br), Laboratório de Biologia Molecular Sanidade Animal, Embrapa Gado de Corte, Campo Grande, Mato Grosso do Sul, Brazil.

TROPIDURUS OREADICUS (Neotropical Ground Lizard). **PREDATION**. Many arthropods are predators of lizards (McCormick and Polis 1982. Biol. Rev. 57:29–58). Lizards of the genus *Tropidurus* (Tropiduridae) are widely distributed in Brazil and species of the *torquatus* group are abundant in savanna and semi-arid vegetation (Rodrigues 1987. Arq. Zool. 31:105–230).

Tropidurus oreadicus is generally abundant in openly vegetated habitats (Colli et al. 1992. J. Herpetol. 26:66–69) and common in Cerrado areas and open enclaves in the Amazon forest (Rodrigues 1987, *op. cit.*). Carvalho-Filho (2008. Herpetol. Rev. 39:230) observed a juvenile *T. oreadicus* predated by a Guira Cuckoo (*Guira guira*) in Belém, Pará state. However few predation events have been recorded involving this species by other vertebrates or arthropods. Herein, we report predation of *T. oreadicus* by a spider in Cerrado area.

At 1116 h on 16 April 2008, we found an adult of *T. oreadicus* (783 mm SVL, 127 mm tail) in Fazenda Floryl (14.04670ºS, 45.89124ºW; datum: SAD69, elev. 900 m), municipality of Jaborandi, Bahia, Brazil. This lizard had been captured and eaten by an adult wolf spider *Lycosa erytrognata* (Lycosidae, Aranae) in a 60-liter bucket pitfall trap in cerrado. In their review, McCormick and Polis (*op. cit.*) considered wolf spiders as predators of amphibian and fish. This is the first record of predation by this wolf spider on a lizard.

We thank Fazenda Floryl/Jatobá for assistance and Janaína C. A. Rodrigues (Laboratório de Aracnídeos/UnB) for spider identification.

Submitted by **ADRIANA BOCCHIGLIERI**, Programa de Pós-graduação em Ecologia, Universidade de Brasília, 70919-970, Brasília, DF, Brazil (e-mail: adriblue@hotmail.com); and **ANDRE FARIA MENDONÇA**, Departamento de Pós-graduação em Zoologia, Museu Nacional, Laboratório de Vertebrados, Universidade Federal do Rio de Janeiro, 21941-590, Rio de Janeiro, RJ, Brazil.

TROPIDURUS OREADICUS (NCN). **CANNIBALISM AND PREY.** *Tropidurus oreadicus* belongs to the *torquatus* group (Frost et al. 2001. Mol. Phylogenet. Evol. 21:352–371) and is distributed in the states of Mato Grosso, Mato Grosso do Sul, Minas Gerais, Goiás, Maranhão, Bahia, and Piauí, from the margins of the lower Tocantins River to Belém. It usually occurs in open areas (Rodrigues 1987. Arq. Zool. 31:105–230). Species of the *torquatus* group are, in general, heliothermic, diurnal, and mostly insectivorous (Rodrigues 1987, *op. cit*.), though sometimes they may also consume small vertebrates (Kiefer and Sazima 2002. Herpetol. Rev. 33:136; Dias and Rocha 2004. Herpetol. Rev. 35:398–398). Here, we report on cannibalism in *T. oreadicus* and on the predation of the gymnophtalmid lizard *Cercosaura schreibersii* by this same tropidurid.

The observations were carried out in the municipality of Porto Velho, state of Rondônia, northern Brazil (08.7619°S, 63.9038°W). The cannibalism was observed in an urban area on 4 August 2009 at 0950 h. An adult male *T. oreadicus* (93 mm SVL, 23 g after prey removal) was standing on a wall, when it noticed the movement of a conspecific juvenile (34 mm SVL, 1.2 g) near the ground; it approached and ate the juvenile. The predator lizard was captured four hours later and its stomach was examined, from which the

smaller lizard was removed pre-digested. The two specimens were deposited as vouchers in the herpetological collection of Universidade Federal do Acre - Campus Floresta (UFACF 2632, UFACF 2633).

The observation of predation on *Cercosaura schreibersii* took place on the 6 August 2009 at 1140 h, in an open area next to a forest edge in a city park in Porto Velho. A juvenile female *T. oreadicus* (35 mm SVL, 1.8 g after prey removal) was caught after ingesting a juvenile gymnophtalmid lizard *C. schreibersii* (19 mm SVL, 0.3 g). The *C. schreibersii* had still been struggling to free itself from the mouth of the *Tropidurus* when first encountered by the observer. The *T. oreadicus* specimen was collected after a few minutes and the prey was removed from its stomach, which accounted for 16.6% of its body mass. The two lizards were deposited as vouchers in the herpetological collection of Universidade Federal do Acre – Campus Floresta. (*T. oreadicus* UFACF 2634; *C. schreibersii* = UFACF 2635).

Submitted by **SAYMON DE ALBUQUERQUE**, Programa de Pós-Graduação em Ecologia e Manejo de Recursos Naturais, Universidade Federal do Acre, 69915-900, Rio Branco, Acre State, Brazil; e-mail: albuquerquesaymon@gmail.com.

TROPIDURUS TORQUATUS (NCN). **AVIAN ATTACK.** *Tropidurus torquatus* is distributed throughout west-central, northeastern (south of the Bahia state), and southern regions of Brazil (Rocha 2000. Ecologia de Restingas e Lagoas Costeiras. NUPEM/UFRJ, Macaé, Rio de Janeiro, Brazil, pp. 99–116; Rodrigues 1987. Arq. Zool. São Paulo 31:105–230). It is active throughout the year and is easily found in open areas and in environments altered by anthropogenic action, such as "roçados," back yards, and gardens. They are seen mainly on rocks, termite mounds, fallen logs, and on the forest floor, and can climb easily on walls and logs (Araújo 1987. Anais de Etologia 5:189–197).

The House Sparrow (*Passer domesticus*) originates from the Middle East. However, this bird spread throughout Europe and Asia reaching the Americas around 1850 (Silva et al. 2007. Anais do VIII Congresso de Ecologia do Brasil, 2 pp.). It was introduced to Brazil early in the 20th century in the city of Rio de Janeiro and spread throughout the south, southeast, west-central, and northeast portions of of Brazil (Sick 1985. Ornitologia Brasileira, uma Introdução, v.II. Brasília: Editora UnB). Today this bird occurs in almost all countries of the world, and is often characterized as an exotic and bioinvasive species (Silva et al. 2007, *op. cit*.). Bioinvasion is defined as the arrival, establishment, and expansion of an exotic species into a region that is outside its known natural distribution, resultant of accidental or intentional dispersion through human activities (Carlton 1996. Biol. Cons. 78:97–106). Introduced exotic species are adaptive not only by their ability to easily establish new populations, but also by becoming invasive, affecting native communities in their respective ecosystems, altering the structures and function of those ecosystems (Reusch and Williams 1998. Oecologia 113:428–441). Here we report the attack of a juvenile lizard *Tropidurus torquatus* by an adult female *Passer domesticus*.

On 22 Nov 2008 at 1800 h, in a residential garden in the city of Araçatuba, state of São Paulo, Brazil, a juvenile *T. torquatus* was observed exhibiting escape behavior from a House Sparrow. The lizard climbed down from a tree, crossed a street, and climbed a residence wall by a garden. The lizard stayed immobile in alert position. At this time, a female House Sparrow that was nesting in the tree from which the lizard had descended flew down in an apparent aggressive attack. The bird pecked at the lizard's head several times. The lizard fled into the vegetation of the garden.

Female House Sparrows are more aggressive than males around nesting sites due to the lack of rivalry between males (which do not establish territories around the nest) (Sick 1997. Ornitologia Brasileira. Nova Fronteira, Rio de Janeiro, 912 pp.). We believe that the female House Sparrow displayed this aggressive behavior in response to the lizard's presence near the bird's nest.

We thank Diego H. Oda for field assistance.

TUPINAMBIS MERIANAE (Common Tegu). **FEEDING BEHAVIOR.** Tegus are diurnal, terrestrial, actively foraging omnivores that often feed on fruit, invertebrates, and small vertebrates (Vanzolini et al. 1980. Répteis das Caatingas. Acad. Bras. Ciências, Rio de Janeiro, RJ, Brazil. 161 pp.; Mercolli and Yanosky 1994. Herpetol. J. 4:15–19; Vitt 1995. Occ. Pap. Oklahoma Mus. Nat. Hist. 1:1–29). Although tegus are known to commonly consume vertebrate eggs (e.g., alligators: A. Lima, pers. comm.; turtles: Gonçalves et al. 2007. Rev. Bras. Zool. 24:1063–1070), eggs are poorly represented (birds: Mercolli and Yanosky, *op. cit*.) or absent (Kiefer and Sazima 2002. Amphibia-Reptilia 23:105–108) in systematic studies of tegu diet. However, this bias might result from the methods typically used to describe lizard diets. For instance, soft or quickly digested food items might not be present or distinguishable in stomach content analysis, a method commonly employed to assess lizard diets. Therefore, the poor representation (or absence) of eggs in tegu diet may simply reflect lizard feeding behavior. Here, I report on an opportunistic observation of predation of an egg of the Solitary Tinamou *(Tinamus solitarius)* by a *Tupinambis merianae* (locally known as *teiú*) that puts perspective on this bias.

At 1245 h on 17 October 2002, I witnessed an adult tegu (ca. 40 cm SVL) eat the egg of a *Tinamus solitarius* at the margin of an old dirt road (19.71°S, 41.825°W; elev. 430 m), in the northern part of the Reserva Particular do Patrimônio Natural Feliciano Miguel Abdala (RPPN-FMA), eastern Minas Gerais, Brazil. I encountered the lizard apparently just after it had begun eating the egg. As soon as it became aware of my presence, the lizard took the egg in its mouth and moved about one meter away. The tegu then placed the egg on the ground, and after a few seconds of watching me, resumed eating. Following this initial movement, it was not disturbed again, a pattern unlike that commonly observed during other encounters with basking tegus in this reserve. My presence may not have further disturbed the tegu because I became immobile at a distance of approximately six meters as soon as I saw it. To access the inside of the egg (62 mm length, 46 mm width), the lizard made a small (25 mm radius) hole on its side through which it lapped up the entire contents. This process lasted approximately two minutes. The tegu then abandoned the eggshell and disappeared into the forest. I collected the eggshell and took it to the RPPN-FMA field laboratory for examination.

It may be that eggs are a resource that tegus often consume, but are rarely recorded because only the egg contents are typically eaten and the eggshell is discarded. As a consequence, soft portions of eggs are unlikely to be recognized in stomach content analyses. This observation emphasizes the importance of direct observations to complement studies of lizard diets in order to fully understand the food resources they use.

I thank R. Cintra, C. Keller, M. Hayes, and J. Shedd for kindly editing and suggestions on the manuscript. A Zoological Society of San Diego graduate fellowship supported the author.

VARANUS MITCHELLI (Mitchell's Water Monitor). **DIET AND FORAGING BEHAVIOR**. The diet of *Varanus mitchelli*, a small arboreal and terrestrial monitor lizard inhabiting tropical Australia, was summarized by Shultz and Doody (2005. *In* Pianka and King [eds.],Varanoid Lizards of the World. Indiana University Press, Bloomington). The species is considered a generalist predator, consuming a wide range of small vertebrates and large invertebrates (Shine 1986. Herpetologica 42:346–360; Losos and Green 1986. Biol. J. Linn. Soc. 35:379–407). However, our knowledge of its diet is based almost solely on dissections of limited museum specimens (but see one account of foraging behavior in Vincent and Wilson 1999. Australian Goannas. Reed New Holland, Sydney). The foraging habits and diet of this species have been little studied in nature.

At 1345 h on 7 June 2009 we observed a pair of Crimson Finches (*Neochmia phaeton*) vocalizing and assuming defensive postures near their nest on a tree limb (*Pandanus aquaticus*) overhanging the water, on the Ord River, ~20 km upstream of Kununurra, Western Australia (15.968611°S, 128.743056°E). Closer inspection revealed a juvenile *V. mitchelli* inside the nest. Our presence flushed the goanna from the nest and it fled along the tree limb to the shore. Inspection of the nest revealed one broken egg and two intact eggs. We were unable to return to the nest site to determine if further predation occurred on the eggs. The weather was partly cloudy with an air temperature of 29.3ºC.

At Mornington Wildlife Sanctuary (MWS), approximately 340 km WSW of the Ord River site, one of us (OM) has monitored Crimson Finch nests for three consecutive breeding seasons between 2006 and 2009. During that study, 397 nests were found that had begun clutch initiation, and of these 237 (59.7%) were preyed upon either during the egg stage or nestling stage. Due to competing objectives, systematic data on predation events were not collected. However, some observations were made that are relevant to the abovementioned predation attempt. *Varanus* species were found in four Crimson Finch nests, of which three were identified as *V. mitchelli*, and the fourth was unidentified. Also, *V. mitchelli* were found within two meters of three additional active finch nests. For comparative purposes, we list the observations of other (potential) predators: An Olive Python (*Liasis olivaceus*) was found in one nest, two unidentified snakes were within 2 m of two nests, and one nest was infested with Green Ants (*Oecophylla smaragdina*). One additional nest preyed upon had a hole opened up in the back of the nest, and seven other nests were 'destroyed' or 'torn apart' by unknown predators (possibly avian predators or monitor lizards).

The three confirmed cases of *V. mitchelli* predation on Crimson Finch nests occurred during the egg stage. However, nestlings may also be taken. Both Crimson Finches and *V. mitchelli* are riparian habitat specialists (Higgins et al. 2006. Handbook of Australian, New Zealand & Antarctic Birds (HANZAB): Boatbill to Starlings Part B. Oxford University Press, South Melbourne; Schultz and Doody, *op. cit.*). Between 55% and 98% of Crimson Finch nests are found in Pandanus (Todd 2002. Austral. Bird Watcher 19:161–171; O. Milenkaya, unpubl. data), a microhabitat often used by *V. mitchelli* (Schultz and Doody, *op. cit.*). It is possible that *V. mitchelli* is a major predator of Crimson Finch nests due to their shared microhabitat. It is also likely that *V. mitchelli* prey upon nests of other riparian bird species nesting in the *Pandanus* such as Purple-crowned Fairy Wrens, *Malurus coronatus* (Rowley and Russell 1993. Emu 93:235–250). At MWS, Purple-crowned Fairy Wrens are obligate-Pandanus nesters, and Bar-shouldered Doves, (*Geopelia humeralis*) and Double-barred Finches (*Taeniopygia bichenovii*) occasionally nest in Pandanus (M. Hall, unpubl. data; O. Milenkaya, unpubl. obs.). Finally, while *V. mitchelli* may prey heavily on bird eggs during the wet season, this may constitute a smaller portion of their diet during the dry season. Crimson Finches, for example, nest mainly during the wet season (December to early June; Todd, *op. cit.*).

The Cane Toad (*Bufo marinus*) is moving rapidly toward the Kimberley region. In the Northern Territory invasive toads caused 71–97% declines in *V. mitchelli*, which die after attempting to ingest the toxic toads (Doody et al. 2008. Anim. Cons. 12:46–53). It is likely that toad-induced declines in *V. mitchelli* at Ord River and MWS will occur, and will greatly reduce *V. mitchelli* predation on nests of Crimson Finches and Purple-crowned Fairy Wrens. Studies are underway to determine the importance of *V. mitchelli* as nest predators on those species, and thus to determine the indirect impact of cane toads on nest success of these Pandanus-nesting birds as cane toads invade.

We are grateful to the Australian Wildlife Conservancy for fund-

ing the Crimson Finch research. We thank J. R. Walters, S. Legge, R. Churchwell, E. Rehm, and the personnel at Mornington Wildlife Sanctuary for their support.

XANTUSIA WIGGINSI (Wiggins' Night Lizard). **DEFENSIVE BEHAVIOR**. With recent morphological and molecular work on the genus *Xantusia*, the number of recognized species in the state of California has grown from three to six in the last decade (Bezy et al. 2008. J. Herpetol. 42:680–688; Leavitt et al. 2007. Mol. Ecol. 16:4455–4481; Lovich 2001. Herpetologica 57:470–487; Sinclair et al. 2004. Am Nat. 163:396–414). The more isolated and geographically restricted of these species (e.g., *X. gracilis*, *X. sierrae*, and *X. wigginsi*) remain poorly known and in need of study. The purpose of this note is to add to the limited knowledge of the behavioral biology of one of these species, *X. wigginsi*.

On 2 January 2010 at 1355 h, an adult *X. wigginsi* was uncovered beneath a decaying *Agave deserti* ca. 7.2 km E of Jacumba, San Diego County (32.636178°N, 116.114167°W; datum WGS84). Once grasped by hand, the night lizard immediately defecated on the captor and initiated mouth-gaping behavior, threatening to bite. The mouth-gaping behavior lasted for ca. one to two minutes while the lizard was in hand and initially positioned for photographs. The mouth-gaping was not elicited by high temperatures as a means of panting, as air temperature at the time of capture was ca. 21°C and the temperature (not taken) within the decaying *Agave* refuge was substantially cooler and damp. The gaping behavior ceased soon after the lizard was placed on a dead piece of *Agave* for the photographs.

Mouth-gaping is a common threat display among Lacertilia, including the much larger congeneric *Xantusia riversiana* (Mautz et al. 1992. Herpetologica 48:271–279). However, this behavioral observation involving *X. wigginsi* is of interest because of the incredibly small size of the species (44 mm maximum snout–vent length; Bezy 2009. *In* Jones and Lovich [eds.], Lizards of the American Southwest: A Photographic Field Guide, pp. 440–443. Rio Nuevo Publishers, Tucson, Arizona), in that the lizard's diminutive mouth appeared incapable of inflicting a bite to a human finger. An attempt to bite was never made by the lizard.

SQUAMATA — SNAKES

BOTHROPS JARARACA (Jararaca). **ALTITUDINAL RECORD.** *Bothrops jararaca* is a generalist species that inhabits several environments in Brazil (from Bahia to Rio Grande do Sul states), Argentina, and Paraguay, from sea level to 1200 m elevation (Sazima 1992. *In* Campbell and Brodie Jr. [eds.], Biology of the Pitvipers, pp. 199–216. Selva, Tyler, Texas; Campbell and Lamar 2004. The Venomous Reptiles of the Western Hemisphere. Cornell University Press, Ithaca, New York. 870 pp.). On 15 October 2006, a *B. jararaca* (SVL = 500 mm) was found in a high altitude field (elevation ca. 1565 m) at the Caraíbas Farm (13.118664°S, 41.381491°W; datum: SAD 69), Chapada Diamantina, municipality of Mucugê, state of Bahia, Brazil. This record increases the altitudinal range of the species by ca. 365 m from previous reports (Sazima, *op. cit.*). The specimen is deposited in Zoological Museum of Universidade Estadual de Santa Cruz (MZUESC 6326).

Submitted by **MARCO ANTÔNIO DE FREITAS,** Programa de Pós-graduação em Zoologia, Universidade Estadual de Santa Cruz, CEP 46.500-000 Rodovia Ilhéus/Itabuna, Ilhéus, Bahia, Brazil (e-mail: philodryas@hotmail.com); **THAÍS FIGUEIREDO SANTOS SILVA,** Biogeographia publicações e consultoria ambiental, Rua E quadra D lote 11, Jardim Aeroporto, CEP 42700-000, Lauro de Freitas, Bahia, Brazil (e-mail: biogeographia@yahoo.com.br); and **DANIEL LOEBMANN**, Departamento de Zoologia, Instituto de Biociências, Universidade Estadual Paulista, Rio Claro, São Paulo, Brazil, Caixa Postal 199, CEP 13506-970 (e-mail: contato@danielloebmann.com).

BOTHROPS LEUCURUS (Jararaca/Bahia Lancehead). **DIET.** *Bothrops leucurus* is a medium-sized terrestrial viperid snake, widespread in the Atlantic Forest of northeastern and eastern Brazil (Campbell and Lamar 2004. The Venomous Reptiles of the Western Hemisphere. Cornell University Press, Ithaca, New York. 870 pp.). The diet of the species consists of small vertebrates with an ontogenetic shift from frog and lizard prey as juveniles to rodents as adults (Freitas 2003. Serpentes Brasileiras. Malha-de-Sapo Publicações, Lauro de Freitas, Bahia, Brazil. 160 pp.). On the morning of 10 November 2002, we collected a juvenile *B. leucurus* (ca. 400 mm SVL) on the ground of the forest at Palmeira farm (15.950833°S, 39.627778°W; datum: SAD 69), municipality of Itapebi, state of Bahia, Brazil. The snake subsequently regurgitated a Marbled Swamp Eel, *Symbranchus marmoratus* (Pisces, Actinopterygii, Synbranchidae). To our knowledge, this is the first record of *B. leucurus* preying on a fish. The specimen is deposited in the Zoological Museum of Universidade Estadual de Santa Cruz (MZUESC 4119).

Submitted by **MARCO ANTÔNIO DE FREITAS,** Programa de pós-graduação em zoologia, Universidade Estadual de Santa Cruz, CEP 46.500-000 Rodovia Ilhéus/Itabuna, Ilhéus, Bahia, Brazil (e-mail: philodryas@hotmail.com); and **DANIEL LOEBMANN**, Departamento de Zoologia, Instituto de Biociências, Universidade Estadual Paulista, Rio Claro, São Paulo, Brazil, Caixa Postal 199, CEP 13506-970 (e-mail: contato@danielloebmann.com).

CAUSUS RHOMBEATUS (Rhombic Night Adder). **PREY SIZE**. Snakes are well known for their ability to consume large prey relative to their body size. In particular, viperids are documented to have high prey to predator mass ratios, with prey exceeding 100% of the snake's mass in some cases (Greene 1983. Am. Zool.

23:431–441). Reports of maximum prey size are important for understanding a species' foraging ecology and the evolution of gape size throughout the evolutionary history of snakes. Yet, detailed records of maximum prey sizes are lacking in many snake clades, particularly those from the Old World. The African viper *Causus rhombeatus* commonly consumes frogs and toads. Herein I report a large prey item for *C. rhombeatus*.

I examined a specimen of *C. rhombeatus* at the Field Museum of Natural History in Chicago (FM 74241). The specimen was collected from Huila, Angola and contained a fully intact toad (probably *Amietophrynus* sp.). The snake measured 566 mm SVL, 20.27 mm head length, 17.21 mm head width and weighed 79 g. The prey item was 95.67 mm SVL, 183 mm total length, 37.59 mm maximum width and weighed 64 g. The prey to predator mass ratio was 81.0% and the prey width to head width ratio was 218.4%. To my knowledge this is the largest prey to predator weight ratio reported for this species.

I thank A. Resestar and the staff at the Field Museum of Natural History in Chicago for their assistance and financial support.

Submitted by **PAUL M. HAMPTON**, Department of Biology, University of Louisiana at Lafayette, Lafayette, Lousiana 70504, USA; e-mail: pmh3227@louisiana.edu.

CROTALUS HORRIDUS (Timber Rattlesnake). **HABITAT USE**. *Crotalus horridus* is threatened or endangered throughout much of its range due largely to human alteration of habitat (Brown 1993. SSAR Herpetol. Circ. 22, 78 pp.). An understanding of habitat use in relation to human impacts will be important in conservation of this species. In the southern Appalachian Mountains, extensive logging and fire suppression in the 20th century resulted in large areas of even-aged closed canopy forest and a reduction in canopy gaps which can be important for reptile species (Greenburg 2001. For. Ecol. Manage. 148:135–144). More recently, rapid suburban development is fragmenting forest habitats across this region (Turner et al. 2003. Landscape Ecol. 18:449–464). Although *C. horridus* are highly dependent on winter dens and summer gestation sites, males and non-gestating females in summer have been reported to favor closed canopy forests with few fallen logs or rocks (Reinert and Zappalorti 1988. Copeia 1988:964–978; Reinert and Rupert 1999. J. Herpetol. 33:45–61). This note describes varying degrees of selection for open canopy sites among four adult *C. horridus* in Jackson County, North Carolina, USA during spring–fall of 2007 and 2008.

In 2007, two adult female *C. horridus* (020 and 040) were captured in early June gestating on a rock dam within a municipal watershed, and two adult males (060 and 081) were captured in early July within an active housing development. Both areas have been extensively logged and are dominated by second growth, closed canopy forests with dense understory shrubs in many areas. Both sites have numerous roads from past logging with road use highly restricted in the watershed and increasing in the development. In the watershed, female 040 remained on the dam until parturition in early September while female 020 left the dam in late July 2007, presumably due to a failed pregnancy. Of the 16 non-gestation locations for 020, three occurred in open canopy sites (Fig. 1). Two of these locations were directly on a seldom used road and one occurred in a natural tree fall opening. After parturition, 040

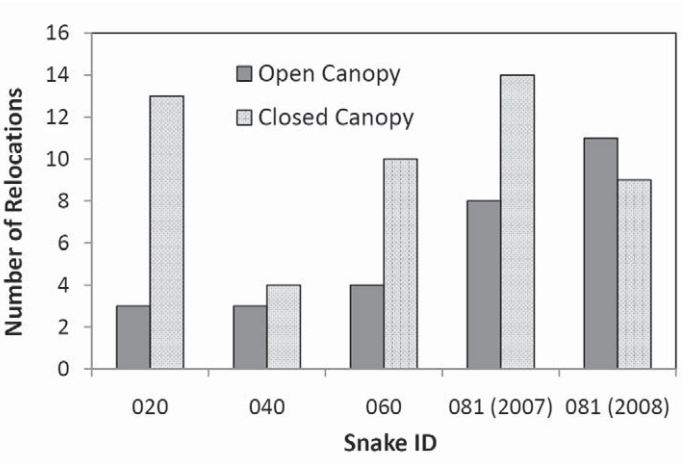

FIG. 1. Use of open vs. closed canopy habitats by four *Crotalus horridus* at two southern Appalachian study sites during Spring–Fall 2007–2008.

moved immediately into adjacent forests using a secondary road as a corridor before moving to a natural tree fall opening. Both snakes used natural log piles while in open sites, and on one occasion 020 used a sapling tree which overhung a log pile.

Within the housing development, male 060 moved onto adjacent private residential lands by August 2007 and used open areas in 4 of 16 of his summer-fall locations (Fig. 1). Three of these locations occurred at road edges (thick grass or shrub cover but no trees) with the remaining location in an old field with thick grass but no tree cover. Male 080 was captured and released within a commercially thinned forest and had eight of 22 locations in 2007 distributed between two such forest stands (Fig. 1). In 2008, 11 of 20 locations for 080 occurred in the same thinned stand in which he was captured. The other thinned stand was avoided entirely in 2008, presumably because of home construction. Of the remaining open canopy locations, one occurred at a road edge just before hibernation in 2007 and the other two occurred in natural openings in the spring of 2008. This male used both natural log piles (spring 2008) and a slash pile from thinning (4 locations in August 2007).

With the predominance of even-aged closed canopy forest in this region, natural and human induced canopy gaps provide benefits to some reptile species and appear to be used to some extent by *C. horridus*. Given limited data, it is unclear if snakes were responding to increased sunlight, shelter from logs and thick shrubs, potential food sources, or other factors. Future investigations should assess the use of open canopy sites, particularly thinned forests, in order to inform potential habitat management for this species.

CROTALUS LEPIDUS (Rock Rattlesnake). **DIET**. The diet of *Crotalus lepidus* reportedly includes arthropods, frogs, small rodents, and reptiles, especially lizards (Ernst and Ernst 2003. Snakes of the United States and Canada. Smithsonian Institution Press, Washington, D.C. 668 pp.). The species has also been shown to feed on *Gyalopion canum* (Chihuahuan Hook-nosed Snake) in the wild and on a *Virginia striatula* (Rough Earthsnake) in captivity (Milstead et al. 1950. Texas J. Sci. 2:543–562; Wright and Wright 1957.

FIG. 1. Adult *Crotalus lepidus* ingesting a freshly killed *Hypsiglena jani* at Indio Mountains Research Station, Hudspeth Co., Texas, USA.

Handbook of Snakes of the United States and Canada. Comstock Publ. Co., Ithaca, New York. 1105 pp.). In addition, Williamson (1971. Herpetol. Rev. 3:18) described cannibalism on two neonate *C. lepidus* born in captivity; one was eaten by a brood mate that five days later was itself consumed by the mother. From the scant information on feeding behavior in the wild, it is assumed that *C. lepidus* consumes nearly any small animal that it can subjugate, although lizards, because they are usually abundant in habitats used by this rattlesnake, are probably the primary diet item (Beaupre 1995. Herpetologica 51:45–56). We report the first known record of *C. lepidus* preying on *Hypsiglena jani* (Chihuahuan Nightsnake), a small colubrid commonly found in the Chihuahuan Desert.

On 27 June 2008, at 2020 h, an adult male *C. lepidus* (SVL = 565 mm; tail length = 60 mm; 175 g), fitted with a 5.0 g temperature-sensitive radio-transmitter (Holohil Systems Ltd, Ontario, Canada), was tracked on Indio Mountains Research Station (IMRS), Hudspeth Co., Texas, USA (30.4635°N, 105.0055°W; datum: WGS84; elev. 1215 m). IMRS is controlled by the University of Texas at El Paso and situated in an area containing rocky mountainous substrates covered by Chihuahuan Desert scrub vegetation. The snake was positioned in a loose coil within an arroyo next to a Prickly Pear (*Opuntia engelmannii*) and was ingesting a freshly killed adult *H. jani* (Fig. 1). The *H. jani* was being swallowed head first in a folded position, which allowed easily identification of the prey item. When the rattlesnake became aware of our presence, it stopped swallowing for about one minute, but then continued on for approximately 20 more minutes until the entire snake was consumed.

We thank A. Rocha, A. Gandara, L. Miranda, and C. Tweedie for their help in the field. Partial funding for field work was supplied by a grant from T&E Inc., the Joseph Family Trust Fund, a G. A. Krutilek Fellowship, and a F. B. Cotton Trust Scholarship to V. Mata-Silva.

DRYMARCHON CORAIS CORAIS (Yellowtail)**. DIET.** *Drymarchon corais corais* is known to prey upon a wide range of vertebrates, including other snakes (Beebe 1946. Zoologica 31:11–52; Cunha and Nascimento 1978. Publ. Avul. Mus. Par. Emílio Goeldi 31:1–128). On 2 February 2006 at 1000 h, while conducting fieldwork in riparian forest at the Acangaú Reserve (17.181389°S, 47.070278°W; datum: Córrego Alegre; elev. 665 m) in the municipality of Paracatu, Minas Gerais, Brazil, one of us (AS) found an adult *D. c. corais* (total length ca. 1250 mm) preying on an adult *Liophis miliaris* (ca. 700 mm total length) on the leaflitter of the forest floor. The snakes were left undisturbed and the *D. corais* swallowed the *L. miliaris* head first over the course of approximately 20 minutes. To the best of our knowledge, this is the first published description of a wild *D. corais* preying upon a snake in Brazil and documents a novel prey species for *D. corais*.

FRANCO** and **MARCELO R. DUARTE**, Laboratório de Herpetologia, Instituto Butantan, CEP 05503-900, São Paulo, SP, Brazil; and **ALEXANDRE SALINO**, Depto. de Botânica, Instituto de Ciências Biológicas, UFMG, CEP 30123-970, Belo Horizonte, MG, Brazil.

HETERODON NASICUS (Plains Hog-nosed Snake). **DIET AND PREY SIZE.** At 1650 h on 20 September 2007, a juvenile female *Heterodon nasicus* (SVL = 178 mm; tail length = 34 mm; 7.6 g without prey item) was collected in the Assiniboine Corridor Wildlife Management Area, Manitoba, Canada (49.6667ºN, 99.5676ºW; datum = NAD83, elev. 348 m). The *H. nasicus* had an enlarged mid-body and after gentle palpation the snake regurgitated an adult *Plestiodon septentrionalis* (Prairie Skink; Fig. 1) that had been recently swallowed tail first (SVL = 77 mm; tail length = 105 mm; 3.9 g). The skink had damage to its tail with punctures at the base of its tail, presumably a consequence of the struggle with the snake. After being scale-clipped for future identification the snake was released at the capture site.

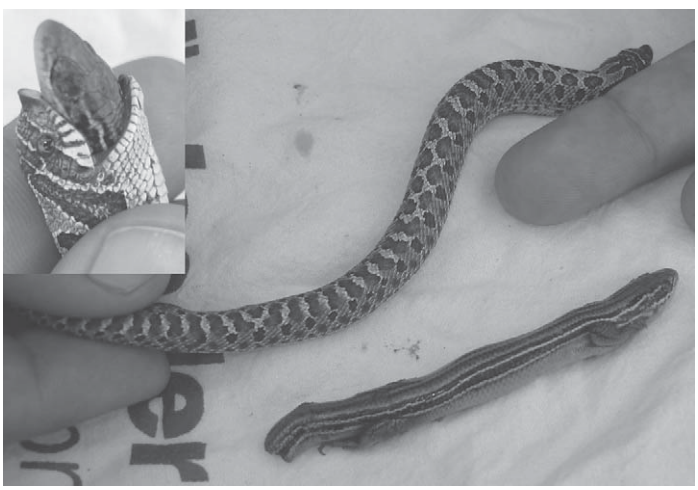

FIG. 1. Juvenile *Heterodon nasicus* with recently regurgitated adult *Plestiodon septentrionalis*. The prey item is also evident in the mouth of the snake prior to regurgitation (inset).

Heterodon nasicus is known to frequently feed on amphibians with a preference for toads, although they also prey upon small mammals, nestlings of ground nesting birds, small lizards, reptile eggs, and snakes (Pendlebury 1976. Can. Field Nat. 90:416–422; Platt 1969. Univ. of Kansas Publ. 18:253–420). *Plestiodon septentrionalis* have been reported in the diet of *H. nasicus* (Oldfield and Moriarty 1994. Amphibians and Reptiles Native to Minnesota. University of Minnesota Press, Minneapolis. 237 pp.), although this the first detailed description. Of considerable note is the size of the prey item (prey/predator mass ratio of 0.51), which is well above the typical meal size for a colubrid snake. Similarly, large anuran prey items (prey/predator mass ratio of 1.06–1.33) recently have been reported for *H. platirhinos* (Steen et al., *in press*. Herpetol. Rev.)

Submitted by **PAMELA L. RUTHERFORD** (e-mail: rutherfordp@brandonu.ca), **NICHOLAS A. CAIRNS**, and **NEIL C. GUSHULAK**, Department of Biology, Brandon University, Brandon, Manitoba, R7A 6A9, Canada.

LEPTODEIRA CUSSILIRIS (Duellman's Cat-eyed Snake). **DIET, CANNIBALISM**. On 26 August 2007 we collected an adult female *Leptodeira cussiliris* (SVL = 220 mm; tail length = 170 mm), in tropical dry forest habitat in Copala, Guerrero, México (16.555975ºN, 98.89425ºW; datum WGS84). When the specimen was examined by dissection, we discovered a partially digested male *L. cussiliris* (verified by Rubén Castro Franco) in the stomach. Duellman (1958. Bull. Amer. Mus. Nat. Hist. 114:1–150) reports that this genus prefers anurans (e.g., Bufonidae, Hylidae, and Ranidae) and lizards (e.g., *Anolis*, *Ctenosaura*, *Ameiva*) as prey. To our knowledge, this represents the first record of cannibalism in *Leptodeira*. Both specimens were deposited in the Colección de Anfibios y Reptiles de la Universidad de Morelos (CARUM).

We thank Rubén Castro Franco for assistance.

PHILODRYAS PATAGONIENSIS (Parelheira). **FEEDING BEHAVIOR**. *Philodryas patagoniensis* is a medium to large terrestrial colubrid that feeds on a wide variety of prey, including mammals, birds, frogs, lizards and other snakes (including conspecifics) (Rocha and Vrcibradic 1998. Ciência e Cultura 50:364–368; Hartmann and Marques 2005. Amphibia-Reptilia 26:25–31; França et al. 2008. Copeia 2008:23–38; López and Giraudo 2008. J. Herpetol. 42: 474–480). Nevertheless, limited information is available on its predatory behavior, particularly in the wild.

On 19 November 2007 the first author observed two events of predation on lizards (*Ameiva ameiva*) by *P. patagoniensis* in the restinga habitat of Massambaba (22.937111ºS, 42.292056ºW; datum WGS 84), Praia Seca district, municipality of Araruama, state of Rio de Janeiro, Brazil. The first event occurred at the border of a trail at 1026 h. An adult *P. patagoniensis* was seen close to the base of a ground bromeliad. Startled by the presence of the observers, the snake started to move away and it was then seen that it was carrying an adult *A. ameiva* in its mouth. The lizard was being held by the side of the body and was apparently alive. Unfortunately, the snake moved into vegetation and disappeared from view before the outcome of the event could be observed.

The second observation occurred about 18 min later, 150 m from the first encounter. This time, the snake was seen moving towards the lizard and capturing it as it ran. During the ensuing struggle, the snake threw two coils of its body around the lizard, bit its head, and then slowly moved its jaws forward until they completely engulfed the immobilized lizard's head (Fig. 1). They remained in that position for about 22 min, during which the lizard occasionally struggled and the snake responded by quickly jerking its head to the side and/or moving its jaws, presumably using its rear fangs to inject toxic secretions into its prey. After the lizard had stopped moving, the snake let it free of its coils and started to swallow it, a process that was completed in about 6 min. It is also noteworthy that, in spite of being venomous (Araújo and Santos 1997. Rev. Soc. Bras. Med. Trop. 30:517–519), *P. patagoniensis* may use a combination of constriction and envenomation to subdue relatively large prey. *Ameiva ameiva* has been reported as prey of many snake species, including *P. patagoniensis* (França et al., *op. cit.*). This medium-sized teiid is one of the most widely distributed lizard species in South America and is probably a frequent component of the diet of *P. patagoniensis*.

FIG. 1. Adult *Philodryas patagoniensis* immobilizing its prey, an adult *Ameiva ameiva*.

SISTRURUS CATENATUS EDWARDSII (Desert Massasauga). **DIET, PREY SIZE, AND FEEDING RELATED MORTALITY**. *Sistrurus catenatus edwardsii* feeds on lizards, small mammals, small snakes, centipedes, and anurans (Holycross and Mackessy 2002. J. Herpetol. 36:454–464). Whiptails of the genus *Aspidoscelis* have been reported to be in the diet of *S. c. edwardsii*, however *A. marmorata* (Marbled Whiptail) has not yet been identified as prey (Holycross and Mackessy, *op. cit.*). This is rather intriguing, given the overlap that exists for both species' known geographic ranges (Degenhardt et al. 1996. Amphibians and Reptiles of New Mexico. Univ. New Mexico Press, Albuquerque. 431 pp.). Furthermore, little published information exists regarding prey size for *S. c. edwardsii*. Here, I report feeding related mortality of an *S. c. edwardsii* following consumption of an adult *A. marmorata*.

At 1018 h on 7 August 2008, I discovered a deceased female *S. c. edwardsii* (TCWC 93556) lying in the bottom of a large sand dune blowout in Lea County, New Mexico, USA (32.7847°N, 103.8089°W; datum: WGS 84, elev. 1173 m). The individual was lying dorsum up, appeared bloated, and had recently died. Both lizard and snake tracks were observed near the dead snake. The individual was collected and dissected to determine what was causing the large bulge in the snake's mid-section. Upon dissection, I discovered that the snake had consumed a female *A. marmorata* (TCWC 93557). The lizard's girth had caused a 35 mm long rupture in the snake's stomach which was likely the cause of death for the snake.

The *S. c. edwardsii* measured 310 mm SVL and 18 g mass post mortem and the *A. marmorata* measured 100 mm SVL and 21 g mass post mortem. This indicates that the snake attempted to ingest a prey item 1.17 times its own mass. This measurement is slight in comparison to the record for snakes (relative prey mass = 1.72; Mulcahy et al. 2003. Herpetol. Rev. 34:64). However, perhaps it illustrates a differential consumption/mortality threshold exists among species or individuals.

This observation is noteworthy for two reasons. First, although the ranges of *S. c. edwardsii* and *A. marmorata* overlap, their trophic relationship had not yet been clarified. Second, it indicates the consumption of large prey items may result in increased energy stores for *S. c. edwardsii*, but the potential threat of death due to a ruptured stomach exists.

THAMNOPHIS MARCIANUS (Checkered Gartersnake). **DIET**. *Thamnophis marcianus* hunt in a variety of habitats and are known to feed on a more diverse group of prey items than many of their congeners (Ernst and Ernst 2003. Snakes of the United States and Canada. Smithsonian Books, Washington, D.C. 668 pp.). During a two-week survey in the state of Coahuila, Mexico, on 31 July 2007 between 2100 and 2200 h, we found a foraging adult *T. marcianus* near Mota de Corona (27.41528ºN, 101.17090ºW; datum: WGS84, elev. 353 m). When captured, the individual immediately regurgitated a partially digested adult *Coleonyx brevis* (Texas Banded Gecko). The prey item was deposited in the herpetological collections of the University of Texas at Arlington (UTA R-55494) along with a photographic voucher of its predator (UTADC 2055). Only three genera of lizards, *Cophosaurus*, *Holbrookia*, and *Aspidoscelis* have been documented as prey for *T. marcianus* (Hampton and Fontenot 2007. Herpetol. Rev. 38:94–95). This is the first report of predation on *C. brevis* or any gecko by *T. marcianus* in the wild.

We thank J. A. Campbell and R. C. Jadin for assistance. The National Science Foundation (DEB-0613802) provided financial support.

THAMNOPHIS SIRTALIS INFERNALIS (California Red-sided Gartersnake). **DIET.** *Thamnophis sirtalis* is a terrestrial-aquatic generalist predator that feeds on a wide variety of prey groups (Fitch 1941. California Fish and Game 27:1–32). Although the diet is broad, amphibians often constitute a major component of their prey (Cunningham 1959. Herpetologica 15:17–19; Fitch, *op. cit.*; Fox 1952. Herpetologica 8:4–8). *Thamnophis sirtalis* can shift prey species in response to temporal availability of prey (Fitch, *op. cit.*) and due to gape limitation, may exhibit ontogenetic shifts in diet. Here I describe the diet of *T. s. infernalis* at a seasonal marsh in California.

I examined *T. s. infernalis* diet at Ledson Marsh, an 11-ha seasonal wetland, located in Annadel State Park, Sonoma County, California, USA (38.4086°N, 122.5995°W; datum: NAD83). The marsh is situated in hilly terrain surrounded by oak woodland and Douglas-fir forest. Winter rains typically fill the marsh to a maximum depth of ca. 150 cm that gradually recedes and the marsh is usually dry by early fall. The marsh is densely vegetated with wetland plants and is inhabited by an abundance of amphibians including: *Pseudacris regilla* (Northern Pacific Treefrog), *Taricha torosa* (California Newt), *T. granulosa* (Rough-skinned Newt), *Rana draytonii* (California Red-legged Frog), and *R. catesbeiana* (American Bullfrog). These species breed during the winter or spring and larvae typically metamorphose from mid-summer through early fall, before the marsh dries. Although abundant in

summer, *R. catesbeiana* tadpoles rarely metamorphose at the marsh due to late-season breeding and a protracted tadpole life stage.

I captured garter snakes at the marsh on 12, 13, 19, and 20 September 1998 using 12 drift fence and trap arrays located along the marsh shoreline, supplemented with hand captures. I hand palpated each snake captured until stomach contents were regurgitated and marked each snake by scale clipping. I grouped snakes into sub-adult and adult age groups based on review of a length frequency histogram that showed a clear bimodal size distribution.

Of the 62 *T. s. infernalis* captured during this study (no recaptures), 19 contained retrievable stomach contents and four snakes had multiple prey items (Table 1). I identified three prey species in the stomachs of snakes including: newly metamorphosed *P. regilla*, larval *Taricha* (species undetermined), and newly metamorphosed *R. draytonii*. No *R. catesbeiana* tadpoles were retrieved. *Rana draytonii* with a mean SVL of 32.1 mm (N = 14) was the largest prey consumed followed by larval *Taricha* with a mean SVL of 22.7 mm (N = 7). A single *P. regilla* was recovered with an SVL of 12 mm. The age (size) of *T. s. infernalis* corresponded to prey species taken (Table 1). Adult snake diet consisted of 84.2% *R. draytonii*, 10.5% larval *Taricha*, and 5.2% *P. regilla*. In contrast, the smaller sub-adult snakes consumed larval *Taricha* exclusively.

This diet study indicates that pre- and post-metamorphic amphibians are important seasonal prey for the Ledson Marsh *T. s. infernalis* population. The relatively high species richness of amphibians at Ledson Marsh apparently maintains a sizeable *T. s. infernalis* population, based on lack of recaptures during this study. *Thamnophis s. infernalis* consumed four of the five amphibian species that occurred at the marsh, the exception being the non-native *R. catesbeiana*. I suspect that *R. catesbeiana* were not taken because during the time of the study, they occurred as either small-sized tadpoles or large adults, both of which are likely outside the size preference for *T. s. infernalis*. Small *R. catesbeiana* tadpoles may be energetically too costly to forage for and adults are too large for snakes to consume. Finally, my results suggest that young *T. s. infernalis* may have a more specialized diet than adults, a pattern that has been noted for *T. sirtalis* in general (Rossman et al. 1996. The Garter Snakes: Evolution and Ecology. Univ. Oklahoma Press, Norman. 332 pp.) and *T. s. tetrataenia* (San Francisco Gartersnake; Larsen et al. 1991. Trans. West. Sect. Wildl. Soc. 27:37–41).

Fitch (*op. cit.*) reported that *R. draytonii* is an important food item for *T. sirtalis*. In my study, *R. draytonii* also appeared to be an important prey item. Juvenile *R. draytonii* were the dominant and largest prey taken by adult snakes, and presumably contributed the largest proportion of consumed biomass. This frog has declined substantially during the past century and is listed as threatened under the Federal Endangered Species Act (Miller et al. 1996. Fed. Reg. 61:25,813–25,833). Although *T. s. infernalis* is not considered rare, *T. s. tetrataenia* has been state and federally listed as endangered since 1971 and 1967, respectively, and the South Coast garter snake (*T. s.* sp.) is a state species of concern (Jennings and Hayes 1994. Amphibian and Reptile Species of Special Concern in California. California Dept. Fish and Game, Rancho Cordova, California. 255 pp.). Recovering *R. draytonii* populations could have substantial benefits for populations of *T. sirtalis* and other species of *Thamnophis*.

TABLE 1. Diet of *Thamnophis sirtalis infernalis* at Ledson Marsh, Sonoma County, California, USA. Prey species included: newly metamorphosed *Pseudacris regilla*, larval *Taricha* spp., and newly metamorphosed *Rana draytonii*.

	Snakes		Stomach Contents		
Snake age class	Mean total length (cm)	N	*Pseudacris regilla*	*Taricha* spp.	*Rana draytonii*
Sub-adult	19.3	26	0	6	0
Adult	41.3	36	1	2	16
All	32.0	62	1	8	16

AMBYSTOMA OPACUM (Marbled Salamander). USA: INDIANA: Gibson Co.: Patoka River National Wildlife Refuge and Management Area. (38.36869ºN, 87.32598ºW; NAD 83). 28 April 2009. Alisha Maves. Verified by Chris Phillips, Illinois Natural History Survey (INHS 2009af). New county record (Minton 2001. Amphibians and Reptiles of Indiana. 2nd ed., revised. Indiana Academy of Science. vii–404 pp.). Single individual found under a wooden pallet among moist leaf litter.

Submitted by **ALISHA MAVES** and **LINDSEY LANDOWSKI,** US Fish and Wildlife Service, Patoka River National Wildlife Refuge, 510 1/2 West Morton Street, P.O. Box 217, Oakland City, Indiana 47660, USA (e-mail: Lindsey_Landowski@fws.gov).

AMPHIUMA TRIDACTYLUM (Three-toed Amphiuma). USA: ARKANSAS: Nevada Co.: 9.7 km E of Prescott off St. Hwy. 24 (33.790561ºN, 93.280106ºW; WGS 84). 06 September 1973. H. W. Robison. Verified by R. Tumlison. Henderson State University Herpetological Collection (HSU 1476). New county record. Specimen is an adult collected from a flooded roadside ditch. *Amphiuma tridactylum* has now been reported from 26 of 75 (35%) counties of the Coastal Plain of Arkansas (Trauth et al. 2004. The Amphibians and Reptiles of Arkansas. Univ. Arkansas Press, Fayetteville. 421 pp.; Plummer et al. 2008. Herpetol. Rev. 39:103).

Submitted by **CHRIS T. McALLISTER**, RapidWrite, 102 Brown Street, Hot Springs National Park, Arkansas 71913, USA (e-mail: drctmcallister@aol.com); and **HENRY W. ROBISON**, Department of Biology, Southern Arkansas University, Magnolia, Arkansas 71754, USA (e-mail: hwrobison@yahoo.com).

DESMOGNATHUS AENEUS (Seepage Salamander). USA: GEORGIA: Bartow Co.: Pine Log WMA, at Stamp Creek Rd. and Stamp Creek; seepage at head of first order branch N of bridge (34.25530°N, 84.68699°W; WGS 84). 12 March 2010. S. Graham and Z. Felix. AUM 38307–38310. Paulding Co.: Paulding Forest WMA, seepage along ravine and first order branch, ~ 50 m S of U.S. Hwy 278; headwaters of Raccoon Creek (33.93520°N, 84.96891°W; WGS 84). 12 March 2010. S. Graham and Z. Felix. AUM 38311–38313. All verified by Craig Guyer. New county records (Jensen et al. 2008. Amphibians and Reptiles of Georgia. University of Georgia Press, Athens. 575 pp.).

Although range maps currently illustrate the distribution of seepage salamanders as continuous from the Blue Ridge Mountains of Georgia southwest through the Talladega Uplands to high elevation sites in Alabama (e.g., Petranka 1998. Salamanders of the United States and Canada. Smithsonian Institution Press, Washington. 587 pp.), few or no records actually support this (Jensen et al. 2008, *op. cit*.; Graham 2009. Herpetol. Rev. 40:232–233). Disjunct populations of this salamander apparently exist (Mount 1975. Amphibians and Reptiles of Alabama. Auburn Printing Co., Auburn, Alabama. 347 pp.; Graham 2009, *op. cit*.), and it was therefore possible that a distribution gap occurred in this area. These new records fill this substantial distribution gap (~ 70 km) between the nearest recorded populations to the NE in Cherokee County, Georgia, and to the SW in Haralson and Carroll Counties, Georgia, confirming that the distribution of this species is indeed continuous along the Talladega Uplands in Georgia as range maps suggest.

Sean Graham is supported in part by NIH grant R01-A149724 to T. Unnasch.

HEMIDACTYLIUM SCUTATUM (Four-toed Salamander). USA: MASSACHUSETTS: Nantucket Co.: Nantucket, southeast shore of Sesachacha Pond near a small tributary stream (41.29231°N, 69.98880°W; WGS 84). 02 October 2009. Collected under a plywood cover board by Andrew A. McKenna-Foster. Color digital photo voucher verified by J. Martinez and J. Rosado. Museum of Comparative Zoology (MCZ A-139525). New county record (Cardoza and Mirik 2009. Massachusetts Division of Fisheries & Wildlife, State Reptiles and Amphibians List). This is the first record of this species on the island of Nantucket.

Submitted by **ANDREW A. MCKENNA-FOSTER**, Maria Mitchell Association, 4 Vestal St., Nantucket, Massachusetts 02554,

USA (e-mail: andrew.mckennafoster@gmail.com); and **SCOTT D. SMYERS**, Oxbow Associates, Inc., P.O. Box 971, Acton, Massachusetts 01720, USA (e-mail: smyers@oxbowassociates.com).

ANURA — FROGS

HYLA VERSICOLOR (Gray Treefrog). USA: PENNSYLVANIA: Clarion Co.: State Gamelands 63 wildlife pond ca. 0.15 km S from Buckhorn Rd. access (41.23532°N, 79.48662°W; WGS 84). 26 June 2009. Luke P. Bobnar and Kurt J. Regester. Verified by Charles Williams. Clarion University Vertebrate Collections and Museum (CUP A024). Adult male. New county record (Hulse et al. 2001. Amphibians and Reptiles of Pennsylvania and the Northeast. Cornell University Press, Ithaca, New York. xii + 419 pp.).

Submitted by **LUKE P. BOBNAR** (e-mail: s_lpbobnar@clarion.edu), and **KURT J. REGESTER**, Department of Biology, Clarion University, Clarion, Pennsylvania 16214, USA.

PSEUDACRIS BRACHYPHONA (Mountain Chorus Frog). USA: ALABAMA: Randolph Co.: Seepage E of U.S. Hwy. 431, 0.64 km S of Big Buck Rd. intersection (33.43538°N, 85.55646°W; WGS 84). 07 March 2010. S. Graham. AUM AHAP-D 269. Digital video file with audio. New county record (Mount 1975. Amphibians and Reptiles of Alabama. Auburn Printing Co., Auburn, Alabama. 347 pp.). Chorus of calling males recorded. GEORGIA: Haralson Co.: (Mountain View Rd. East, 50 m N of Tallapoosa River (33.87875°N, 85.16297°W; WGS 84). 12 March 2010. S. Graham. AUM AHAP-D 271. Video file with audio. Single male recorded calling. GEORGIA: Polk Co.: At intersection of Cobb Mountain Rd. and Mountain View Rd. (33.90718°N, 85.19728°W; WGS 84). 12 March 2010. S. Graham. AUM AHAP-D 270. Video file with audio. Single male recorded calling. New county records (Jensen et al. 2008. Amphibians and Reptiles of Georgia. University of Georgia Press, Athens, Georgia. 575 pp.). All identifications verified by Craig Guyer.

Range maps illustrate the distribution of *Pseudacris brachyphona* as continuous from the Blue Ridge Mountains of Georgia west through the Talladega Uplands to high elevation sites in Alabama (Mount 1975, *op. cit.*; Jensen et al. 2008, *op. cit.*), however, records are lacking for portions of this presumably continuous range. These new records fill a distribution gap (~ 70 km) between the nearest recorded populations to the E in Paulding County, Georgia, and to the SW in Cleburne County, Alabama, confirming that populations occur along the Georgia section of the Talladega Uplands, and that the distribution of this species is indeed continuous here as range maps suggest.

Submitted by **SEAN P. GRAHAM,** Auburn University, Department of Biological Sciences, 331 Funchess Hall, Auburn, Alabama 36849, USA; e-mail: grahasp@auburn.edu.

PSEUDACRIS CRUCIFER (Spring Peeper). USA: GEORGIA: Haralson Co.: Coppermine Rd., 100 m E of intersection of Coppermine Rd. and Corinth-Five Points Rd. (33.83487°N, 85.12062°W; WGS 84). 12 March 2010. S. Graham. AUM AHAP-D 272. Video file with audio. Verified by Craig Guyer. New county record (Jensen et al. 2008. Amphibians and Reptiles of Georgia. University of Georgia Press, Athens, Georgia. 575 pp.). Chorus of multiple males recorded.

Submitted by **SEAN P. GRAHAM,** Auburn University, Department of Biological Sciences, 331 Funchess Hall, Auburn, Alabama 36849, USA; e-mail: grahasp@auburn.edu.

PSEUDACRIS CRUCIFER (Spring Peeper). USA: TENNESSEE: Hamilton Co.: Volunteer Army Ammunition Plant site (35.10437°N, 85.13053°W; WGS 84). 20 April 2009. Daniel S. Armstrong, Joseph F. Simpson, Thomas P. Wilson. Verified by C. Manis. UT Chattanooga Natural History Museum (TPW/UTCH-ERP 4657). First record for Hamilton County (Redmond and Scott 1996. Atlas of Amphibians in Tennessee. Misc. Publ. No. 12, The Center for Field Biology, Austin Peay State University, Clarksville, Tennessee, 19 pp. Hard copy and Internet [http://www.apsu.edu/amatlas/]. Accessed 20 April 2009). Specimen collected using a drift fence/pitfall array surrounding an ephemeral wetland. Voucher collected under Tennessee Wildlife Resources Agency Permit 3082 and UTC AUP No. 0408TPW-04.

Submitted by **JOSEPH F. SIMPSON** (e-mail: joseph-simpson@utc.edu), **DANIEL S. ARMSTRONG** (e-mail: daniel-armstrong@utc.edu), and **THOMAS P. WILSON**, Department of Biological and Environmental Sciences, University of Tennessee at Chattanooga, 615 McCallie Avenue, Chattanooga, Tennessee 37403, USA (e-mail: thomas-wilson@utc.edu)

PSEUDACRIS FERIARUM (Upland Chorus Frog). USA: GEORGIA: Haralson Co.: Coppermine Rd., 100 m E of intersection of Coppermine Rd and Corinth-Five Points Rd. (33.83487°N, 85.12062°W; WGS 84). 12 March 2010. S. Graham. AUM AHAP-D 272. Video file with audio. Chorus of calling males recorded. Paulding Co.: Seepage at head of first order branch S of U.S. Hwy. 278 (33.93227°N, 84.97599°W; WGS 84). 12 March 2010. Z. Felix. AUM AHAP-D 267. Audio file. Chorus of calling males recorded. All verified by Craig Guyer. New county records (Jensen et al. 2008. Amphibians and Reptiles of Georgia, University of Georgia Press, Athens, Georgia. 575 pp.).

Submitted by **ZACH I. FELIX,** Biology Department, Reinhardt College, Waleska, Georgia 30183, USA (e-mail: zif@reinhardt.edu); and **SEAN P. GRAHAM,** Auburn University, Department of Biological Sciences, 331 Funchess Hall, Auburn, Alabama 36849, USA (e-mail: grahaspauburn.edu).

GYMNOPHIONA — CAECILIANS

GEOTRYPETES SERAPHINI (Gaboon Caecilian). REPUBLIC OF CONGO. Mayongongo Village (04.11ºS; 14.57ºE; no datum available; elev. 331 m.) 09 December 2008. USNM 576262. Verified by George Zug. First records from the southern Republic of Congo. Two individuals (one collected) captured by villager, Célestine Louboko, while digging at edge of river in degraded forest near manioc field. Specimens were preserved, including tissue sampling and testing for chytrid fungus by Ange-Ghislain Zassi-Boulou and Sylvestre Boudzoumou, Groupe D'Etude et de Recherche sur la Diversité Biologique, Brazzaville, Republic of Congo. Previously reported from Gabon, Democratic Republic of Congo, Ivory Coast, and Ghana (Dumeril 1859. Arch. Mus. Natl. Hist. Nat. Paris 10:222; Laurent 1974. Copeia 1974:787–788; Rödel and Branch 2002. Salamandra 38:245–268; Rödel et al.

2005. Salamandra 41:107–127). Presence in southern Republic of Congo assumed (e.g., www.amphibiaweb.org), but not previously documented.

Submitted by **ANGE-GHISLAIN ZASSI-BOULOU** and **SYLVESTRE BOUDZOUMOU**, GERDIB (Groupe D'Etude et de Recherche sur la Diversité Biologique), BP: 2400, Brazzaville, Republic of Congo; and **KATE JACKSON**, Whitman College, Walla Walla, Washington 99362, USA (e-mail: jacksok@whitman.edu).

***POTAMOTYPHLUS KAUPII*.** BRAZIL: MARANHÃO: Municipality of Estreito (06.58459ºS, 47.44936ºW; no datum available), Tocantins River, Estreito hydroelectric power plant (UHE Estreito). 16 September 2007. I. Martins. Herpetological collection Museu de Zoologia da Universidade de São Paulo, São Paulo, Brazil (MZUSP 141871). Verified by H. Zaher. Previous general references to Amazon and Orinoco drainage systems of Colombia, Venezuela, Ecuador, Peru, and Brazil, below 500 m (Caramaschi and Pombal 2000. Herpetol. Rev. 31:49; Frost 2010. Amphibian Species of the World: an Online Reference. Version 5.4 [8 April 2010]. Electronic database accessible at: http:research.amnh.org/vz/herpetology/amphibia/, American Museum of Natural History, New York; Taylor 1968. The Caecilians of the World. A Taxonomic Review. Univ. Kansas Press, Lawrence. xiv + 848 pp.; Wilkinson et. al. 2004. IUCN Red List of Threatened Species. Version 2009. A Taxonomic and Geographical Reference. Allen Press, Inc., Lawrence, Kansas. vi+732 pp.). First record for the state of Maranhão and upper Tocantins River and also the first record for Cerrado biome. this is southern limit of the distribution, located 800 km from the previous southern limit of distribution at Amapá (Caramaschi and Pombal 2000, *op. cit.)*.

CROCODILIA — CROCODILIANS

ALLIGATOR MISSISSIPIENSIS (American Alligator). USA: GEORGIA: Miller Co.: Mayhaw Wildlife Management Area, 0.26 mi NE junction Griggs Lucille Road and Cypres Creek (31.19848°N, 84.79229°W; WGS84). 03 March 2006. Collected by A. M. Durso and UGA herpetology class. Verified by Kenneth L. Krysko. FLMNH 157207. First county record documented by a voucher (Jensen et al. 2008. Amphibians and Reptiles of Georgia. University of Georgia Press, Athens, Georgia. 575 pp.). The carcass of a subadult *A. mississipiensis* was found by the margin of a pond. This record lies ca. 18.7 km S of a 1997 record from Early County, Georgia (Moulis 1997. Status Survey of Barbour's Map Turtle [*Graptemys barbouri*] in Georgia. Unpubl. report to Georgia DNR. 38 pp. + appendices).

Submitted by **ANDREW M. DURSO**, Eastern Illinois University, Department of Biological Sciences, Charleston, Illinois 61920, USA; e-mail: amdurso@gmail.com.

TESTUDINES — TURTLES

APALONE MUTICA MUTICA (Midland Smooth Softshell). USA: IOWA: Butler Co.: S bank of West Fork Cedar River, ca. 1 km NE of Co Rd T-55 bridge, 9.2 km N of New Hartford (42.636867°N, 92.6379°W; WGS84). 278 m elev. 28 June 2004. Jeffrey W. Tamplin and Matt Keller. Verified by James W. Demastes. University of Northern Iowa Vertebrate Collection (UNI-JWT13). New county record. Extends the species' range into the West Fork Cedar River drainage in Iowa. *Apalone mutica* inhabits the Missouri, Mississippi, lower Cedar, Iowa, and Des Moines river drainages in Iowa but is thought to be absent from interior river systems in northern Iowa (Christiansen and Bailey 1997. The Lizards and Turtles of Iowa. Iowa Department of Natural Resources, Nongame Technical Series No. 3. Des Moines, Iowa. 20 pp.; Ernst and Lovich 2009. Turtles of the United States and Canada. 2nd edition. Johns Hopkins Univ. Press, Baltimore, Maryland. 828 pp.; http://www.herpnet.net/Iowa-Herpetology/). Adult *A. mutica* have been trapped and released along the West Fork Cedar River in Butler County, Iowa since 2004 and successful nesting has been observed since 2006. Habitat is riverine with a sand and gravel bottom, containing sand bars and sandy stream banks; banks are lined with patchy clearings of grasses and willow (*Salix* sp.) saplings, interspersed among deciduous woodlands.

Submitted by **JEFFREY W. TAMPLIN**, Department of Biology, University of Northern Iowa, 1227 W 27th Street, Cedar Falls, Iowa 50614, USA; e-mail: jeff.tamplin@uni.edu.

MORENIA PETERSI (Indian Eyed Turtle). INDIA: UTTARKHAND: Haridwar, Bhikampur, Laksar Road (29.44ºN, 78.02ºE; no datum available). Archana Bahuguna. 29 August 2009. ZSI NRC 02. Verified by Indraneil Das. First record from Uttarakhand State. From marshy area. Previously known from Assam, Bihar, West Bengal, and Uttar Pradesh in India, as well as Nepal and Bangladesh (Das 1995. Turtles and tortoises of India. Oxford University Press, Bombay. x + 176 pp.). Extends range west ca. 400 km from Dudhwa National Park, Uttar Pradesh, reported by Javed and Hanfee (1995. Hamadryad 20:21–26).

Submitted by **ARCHANA BAHUGUNA**, Northern Regional Centre, Zoological Survey of India, 218, Kaulagarh Road, Dehra Dun 248 195 Uttarakhand, India; e-mail: archana.bahuguna65@gmail.com.

TERRAPENE CAROLINA (Eastern Box Turtle). USA: INDIANA: Gibson Co.: Patoka River National Wildlife Refuge and Management Area (38.37535ºN, 87.35398ºW; NAD 83). 22 April 2009. Sarabeth Klueh, Angela Garcia, and Alisha Maves. Verified by Chris Phillips, Illinois Natural History Survey (INHS 2009ah). New county record. (Minton 2001. Amphibians and Reptiles of Indiana. 2nd ed., revised. Indiana Academy of Science. vii + 404 pp.)

Submitted by **SARABETH KLUEH** (e-mail: sklueh@dnr.in.gov) and **ANGELA GARCIA**, Wildlife Diversity Section, Indiana Department of Natural Resources Division of Fish and Wildlife, 553 E. Miller Drive, Bloomington, Indiana 47401, USA; **ALISHA MAVES** and **LINDSEY LANDOWSKI** (e-mail: Lindsey_Landowski@fws.gov), US Fish and Wildlife Service, Patoka River National Wildlife Refuge, 510 1/2 West Morton Street, P.O.

Box 217, Oakland City, Indiana 47660, USA.

TRACHEMYS VENUSTA (Mesoamerican Slider). USA: FLORIDA: Gilchrist Co.: Santa Fe River, 1.2 km downstream from Rum Island (29.834354°N, 82.690575°W; datum WGS84). 19 January 2010. Matthew H. Kail. Verified by Kurt Buhlmann and Michael Seidel. Florida Museum of Natural History (UF 157304). New state record. Adult male (straight carapace length 243 mm, plastron length 216 mm, mass 1690 g) captured by hand at 2130 h along the northern shoreline. High leech load (80–100 leeches) and presence of algae on carapace suggest that this is not a recently released captive. This non-native species may potentially harm the closely related native Yellow-bellied Slider (*Trachemys scripta scripta*) population through interbreeding and genetic introgression.

DAREVSKIA BRAUNERI SZCZERBAKI (Rock Lizard). GEORGIA: ABKHAZIA: Gudauta District: Lzaa village, Pitsunda-Myussera Hills. ZISP 24397, 25816–25818. 17 April 2006. Three specimens found by Konstantin Milto and Mark Pestov. Several specimens were registered in 5–7 July, 7–9 August 2008, and 7–12 August 2009 by Mark Pestov and Olga Bezman-Moseyko. Verified by Ilya S. Darevsky. Lizards observed on clay-rock cliffs of Black Sea coast between Lzaa settlement (43.16813ºN, 40.4108ºE; no datum available) and mouth of Mysra River (43.15009ºN, 40.45921ºE). Known from a small territory on northeastern coast of Black Sea in Krasnodar Region, Russia, and a subspecies endemic to Crimea-Novorossisk subprovince of East Mediterranean Province in Caucasus, inhabiting narrow coastal zone from Anapa

town to Cape of Utrish. This new locality, 297 km to southeast from earlier localities, may be the southernmost border of the range, and is a first record for the country.

Submitted by **KONSTANTIN D. MILTO** (e-mail: coluber@zin.ru), **MARK V. PESTOV**, and **OLGA S. BEZMAN-MOSEYKO**, Zoological Institute, Department of Herpetology, St. Petersburg, Universitetskaya emb., 1, 199034, Russia.

MESALINA BREVIROSTRIS (Short-nosed Desert Racer). IRAN: SISTAN & BALUCHISTAN PROVINCE: Gando Protected Area: Garm Beet (61.30ºN, 25.47ºE; ca. 146 m elev.). Nastaran Heydari. 20 October 2008. Verified by Steven C. Anderson. Zoology Museum Golestan University, ZMGU 2429. First confirmed record for Sistan and Baluchistan Province. Associated with *Phoenixdactylifera*, *Prosopis cineraria*, and *Nannorhops ritchieana* in lowland sandy hills. 850 km E of nearest record (Qeshm Island and Mahor Birinji; Anderson 1999. The Lizards of Iran. Society for the Study of Amphibians and Reptiles, Ithaca, New York. 415 pp.; Haas and Werner 1969. Bull. Mus. Comp. Zool., Harvard Univ. 138[6]:327–405).

PLESTIODON FASCIATUS (Five-lined Skink). CANADA: ONTARIO: Lambton Co.: Village of Point Edward, ca. 60 m from shore of St. Clair River (42.992970ºN, 82.410727ºW; WGS 84). 20 May 2009. Daniel W. A. Noble and Jonathan D. Choquette. Verified by Ross D. MacCulloch. Royal Ontario Museum photographic vouchers (ROMdm 00251–00254). First municipality record and first observations in vicinity since 1932. Nearest record is historical from ca. 6 km S in the city of Sarnia, Ontario in 1932 (NMC 1740; Patch 1934. Copeia 1934:50–51). The Sarnia population (NHIC EO 16753) is considered extirpated by Ontario Ministry of Natural Resources Natural History Information Centre (NHIC). Records exist for only two other distant locations in Lambton County (both extant): Walpole Island (NHIC EO 1218) 45 km S and Pinery Provincial Park (NHIC EO 1212) 55 km NE. Three skinks (1 male, 1 female, 1 juvenile) were observed in a pile of logs, railway ties, and metal pipes in an isolated marina waste area. Two juveniles were observed 26 August and five juveniles on 11 September 2009 at same site. All were actively foraging or basking.

HETERODON PLATIRHINOS (Eastern Hog-nosed Snake). USA: ILLINOIS: Schulyler Co.: 2.3 km SW of Sugar Grove, 0.2 km N of jct. Co. Rd. 1700E (La Grange Lock Road.) and Co. Rd 270N (Quarry Road.) on Co. Rd. 1700E (40.0122°N, 90.5871°W; NAD 83). 10 May 2007. J. E. Petzing and K. L. Knuffman. Verified by C. A. Phillips. Illinois Natural History Survey (INHS) 20531. First county record (Phillips et al. 1999. Field Guide to Amphibians and Reptiles of Illinois. Illinois Nat. Hist. Surv. Manual 8, Champaign, Illinois. 300 pp.). DOR adult.

Submitted by **JOHN E. PETZING**, 1018 Prickett Avenue, Edwardsville, Illinois 62025, USA; e-mail: jepetzing@yahoo.com.

OPHEODRYS VERNALIS (Smooth Green Snake). USA: MINNESOTA: Houston Co.: County Hwy 26 ca. 4.8 km N of Reno (43.64493°N, 91.27580°W; WGS 84). 19 September 2009. Found DOR, photographic records were deposited in the James Ford Bell Museum (JFBM P316). Verified by Kenneth H. Kozak and Amy M Luxbacher. Oldfield and Moriarty (1994. Amphibians & Reptiles Native to Minnesota. Univ. Minnesota Press, Minneapolis. 237 pp.) list no museum record for this species in Houston County but do plot its occurrence with a symbol representing sightings or literature records. To the best of our knowledge this is the first vouchered specimen for Houston County.

Submitted by **ERICA P. HOAGLUND**, Minnesota Department of Natural Resources, Division of Ecological Resources, Nongame Wildlife, 1335 Oakdale Ave. Apt. 209, West Saint Paul, Minnesota 55118, USA (e-mail: Erica.Hoaglund@dnr.state.mn.us); and **CHRISTOPHER E. SMITH**, Department of Fisheries, Wildlife, and Conservation Biology, University of Minnesota, 1980 Folwell Avenue, Saint Paul, Minnesota 55108, USA; (e-mail: smit4155@umn.edu).

SONORA SEMIANNULATA SEMIANNULATA (Variable Groundsnake). USA: NEVADA: Lander Co.: Shoshone Range, 34.8 air miles N of Austin (39.99452°N, 117.14979°W; WGS84), elev. 1680 m. 12 June 2009. J. Shedd. Verified by J. Vindum. California Academy of Sciences photo voucher (HPV 62). First documented account from Lander County aside from two unverified reports from the vicinity of Battle Mountain (L. Teske, pers. comm.). Only one other specimen (CAS-SUR 10032) of this species is formally documented from Lander County, at 22 mi E of Battle Mountain. This distance from Battle Mountain appears to actually be Eureka County by both road or air miles. Found under rock after heavy rains at 1100 h. The specimen was orange and black-saddled morph. Predominant vegetation consisted of *Artemisia tridentata*, *Atriplex confertifolia*, and *Chrysothamnus viscidiflorus*. Sheds from two other individuals also found in the vicinity under rocks.

THAMNODYNASTES ALMAE (NCN). **BRAZIL:** PARAÍBA**:** Cabaceiras: Fazenda Bravo (7.483333ºS, 36.283333ºW; WGS84). 28 February 2003. S. Abrantes et al. Universidade Federal da Paraíba (UFPB 4263); BAHIA: Itiúba (10.700000ºS, 39.850000ºW; WGS84). 5–9 May 1973. Expedition ABC-MZUSP. Museu de Zoologia da Universidade de São Paulo (MZUSP 5433–34) and Paulo Afonso (9.400000ºS, 38.216667ºW; WGS84). 22 March and 10 April 1988. Anonymous collector. Museu de Zoologia da Universidade Federal da Bahia (MZUFBA 131–38); PERNAMBUCO: Petrolândia (9.133333ºS, 38.300000ºW; WGS84). 20 April 1988. Companhia Hidroelétrica do São Francisco. Instituto Butantan (IB 52119). ALAGOAS: Piranhas (9.616667ºS, 37.750000ºW; WGS84). 29 April 1994. Companhia Hidroelétrica de Xingó. Museu de Zoologia da Universidade Federal da Bahia (MZUFBA 847). All verified by F. L. Franco. The species was known from the type locality, Rodelas municipality, Bahia state (Franco and Ferreira 2002. Phyllomedusa 1:57–74) and a recent record in Milagres, Ceará state (Roberto et al. 2009. Herpetol. Rev. 40:238). First records for the states of Paraíba, Pernambuco, and Alagoas, all in Caatinga habitats, extending range ca. 289 km NE and the two new records from Bahia extend the range ca. 244 km S from type locality (Franco and Ferreira 2002, *op. cit.*). Funded by FAPESP (2009/50627-4).

Submitted by **THAÍS BARRETO GUEDES,** Laboratório de Ecologia e Evolução, Instituto Butantan, Av. Vital Brazil 1500, CEP 05503-900, São Paulo, SP, Brazil; e-mail: thaisguedes@butantan.gov.br.

THAMNOPHIS PROXIMUS PROXIMUS (Orange-striped Ribbonsnake). USA: IOWA: Bremer Co.: Sweet Marsh Wildlife Management Area, 1.6 km NW of Co Rd C-28 and Sable Avenue Intersection, 3.3 km NE of Tripoli (42.812997°N, 92.217967°W; WGS84). 303 m elev. 30 April 2004. Jeffrey W. Tamplin, Thomas F. Bierman, and Gretchen R. Spies. Verified by James W. Demastes. University of Northern Iowa Vertebrate Collection (UNI-JWT15). New county record extends the species' range into northeastern Iowa. *Thamnophis proximus* occurs across southern Iowa but was thought to be absent from north-central and northeastern Iowa (Christiansen and Bailey 1990. The Snakes of Iowa. Iowa Department of Natural Resources, Nongame Tech. Ser. No. 1. Des Moines, Iowa. 16 pp.; Ernst and Ernst 2003. Snakes of the United States and Canada. Smithsonian Books, Washington, D.C. 668 pp.; http://www.herpnet.net/Iowa-Herpetology/). Two adults were observed mating at ca. 1530 h. After mating was completed the male was collected as a voucher specimen. Habitat was a grassy clearing with forbs and small saplings, adjacent to marshes and cultivated fields.

More Range Extensions for Papuan Reptiles and Amphibians

FRED KRAUS
Bishop Museum, 1525 Bernice Street, Honolulu, Hawaii 96813, USA
e-mail: fkraus@hawaii.edu

The herpetofauna of the Papuan region—comprising New Guinea, the Solomon Islands, and associated satellite islands—is extremely rich but remains relatively poorly known. Hundreds of species likely remain to be discovered, scores are known but remain to be described, geographic ranges of known species are often poorly understood, and important parts of the region remain sparsely surveyed. Recent work has considerably expanded our knowledge of species' distributional ranges in this region (Günther 2003; Kraus and Allison 2004, 2006a; Kraus and Shea 2005), but much remains to be done. Much of this recent expansion in our understanding has resulted from expeditions to previously unstudied localities. However, additional relevant information already resides in museum collections but has remained unsurveyed. Herein I report a number of significant range extensions for amphibians and reptiles from New Guinea, the majority of these records coming from the holdings of the Australian Museum in Sydney and the Bishop Museum in Honolulu, but supplemented with additional records from the Museum of Comparative Zoology and United States National Museum. Coordinates for BPBM specimens use the AGD66 datum unless otherwise noted; those from other museums are taken from their catalogues, converted by me to decimal degrees, and presumably were taken from maps using the AGD66 datum.

Frogs

Albericus darlingtoni. PAPUA NEW GUINEA: Southern Highlands Prov.: E slope Mt. Itukua, Muller Range, 5.66954°S, 142.62334°E (WGS84 datum), 2177 m elev. 26–30 March 2009. F. Kraus, J. Anamiato. BPBM 33664–33668. Range extension of ca. 125 km WNW of nearest locality at Mendi (Menzies 1999).

Albericus gunnari. PAPUA NEW GUINEA: Central Prov.: Dorobisoro, 9.4592391ºS, 147.9371584ºE, 600 m elev. 7–8 October 2003. F. Kraus. BPBM 18347–51; halfway between Laronu and Mimai, 8.4501811ºS, 147.9772933ºE, 1000 m elev. 14 February 2004. F. Kraus. BPBM 19223–33. Range extension of ca. 40 km to NE of type locality (Menzies 1999).

Choerophryne burtoni. PAPUA NEW GUINEA: Southern Highlands Prov.: E slope Mt. Itukua, Muller Range, 5.67046°S, 142.63038°E (WGS84 datum), 2037 m elev. 25 March 2009. native collectors. BPBM 33671. Range extension of ca. 80 km to NW of type locality at Moran area of same province (Richards et al. 2007).

Cophixalus riparius. PAPUA NEW GUINEA: Madang Prov.: Fungoi, Kaironk Valley, Schrader Mts., 5.333333ºS, 144.41666667ºE. 14 December 1963–2 January 1964. H. G. Cogger. AMS R22667–22756. First record for province and for Schrader Mts.; range extension of ca. 80 km NW of nearest locality at Mt. Wilhelm (Zweifel 1962).

Cophixalus shellyi. PAPUA NEW GUINEA: Madang Prov.: Fungoi, Kaironk Valley, Schrader Mts., 5.333333ºS, 144.41666667ºE. 24 December 1963. H. G. Cogger. AMS R23086, 23123. First records for Schrader Mts. and range extension of ca. 60 km NW of nearest locality at Wahgi-Sepik Divide (Zweifel 1980).

Cophixalus variabilis. PAPUA NEW GUINEA: Central Prov.: Sogeri Plateau, Itikinumu Rubber Plantation. 14 November 1971. G. R. Zug. USNM 197456, 231508; Northern Prov.: 10 km NNW Popondetta. 27 December 1971. G. R. Zug. USNM 197457. First record is a range extension of ca. 20 km N of previously northernmost record along Musgrave River; second is a new provincial record and first report of species along northern versant of Owen Stanley Mts. (Kraus and Allison 2006b).

Hylarana daemeli. PAPUA NEW GUINEA: New Ireland Prov.: Napus, New Hanover Island. 29 August 1973. P. Comorford. AMS R41249; Taskul, New Hanover Island. 28 August 1973. P. Comorford. AMS R41250. First record for province (Menzies 2006).

Hylarana milneana. PAPUA NEW GUINEA: Morobe Prov.: Bulolo. No date. C. Gunther. AMS R12186, 12188, 12190–95; Northern Prov.: Inamaturu, Mt. Lamington, 8º56'S, 148º10'E. No date. C. T. McNamara. AMS R9874. First records for each province, and latter is range extension of 270 km to the N; previously known only from Milne Bay and Central provinces (Kraus and Allison 2007).

Hylophorbus richardsi. PAPUA NEW GUINEA: Southern Highlands Prov.: E slope Mt. Itukua, Muller Range, 5.66954°S, 142.62334°E (WGS84 datum), 2177 m elev. 20–27 March 2009. F. Kraus, J. Anamiato, and native collectors. BPBM 33756–62. Range extension of ca. 55 km to NW of type locality at Mt. Sisa (Günther 2001).

Lechriodus platyceps. PAPUA NEW GUINEA: West Sepik Prov.: summit Mt. Somoro, Torricelli Mts., 3.392ºS, 142.133ºE. 8 March 1990. T. Flannery. AMS R136293. Second record for country, first record for Torricelli Mts., and range extension of ca. 110 km E of

Bewani Mts. (Kraus and Allison 2006a).

Liophryne allisoni. PAPUA NEW GUINEA: Central Prov.: 2.3 km SSW Fane, 8.56933ºS, 147.07675ºE, 1800 m elev. 5 October 2003. F. Kraus. BPBM 18315. New provincial record and range extension of ca. 140 km to S of area around Wau (Zweifel 2000).

Litoria auae. PAPUA NEW GUINEA: Southern Highlands Prov.: Bobole, 6.20ºS, 142.76666667ºE. October 1985. S. Donnellan. AMS R132359–71; Namosado, 6.25ºS, 142.783333ºE. 1985. S. Donnellan. AMS R132380–81. In describing this species and *L. kumae*, Menzies and Tyler (2004) noted that five poorly preserved specimens from these localities (in SAM) appeared to be *L. kumae*. However, all AMS specimens listed above have white spots, have lighter ground color than seen in *L. kumae*, and are larger (male SVL = 29.3–35.3, N = 12; female SVL = 34.2–39.8, N = 3) than that species; they clearly fit the diagnosis of *L. auae*. They thus bring the range of *L. auae* to at least the edge of the range of *L. kumae* and serve to fill in the gap between eastern populations of *L. auae* and the Ok Ma isolate to the west (Menzies and Tyler 2004).

Litoria kumae. PAPUA NEW GUINEA: Southern Highlands Prov.: 1.2 km N Tangi, 5.64700ºS, 142.65259ºE (WGS84 datum), 1660 m elev. 5 April 2009. Native collectors. BPBM 33991–400. Range extension of ca. 35 km to NW of Tari for this restricted-range species (Menzies and Tyler 2004).

Litoria purpureolata. PAPUA NEW GUINEA: West Sepik Prov.: Imonda, 3.3333ºS, 141.166667ºE. 1 March 1990. P. German. AMS R135573; vicinity of Utai aerodrome, 3.389ºS, 141.585ºE, 210 m elev. 26 April 1986. A. Allison. BPBM 14463–65, 14467; base of Mt. Sumbau, 3.38333ºS, 142.5333ºE. 8 March 1990. P. German. AMS R135576. First records for country, and range extensions of ca. 280 km, 330 km, and 470 km E of type locality (Oliver et al. 2007).

Litoria pygmaea. PAPUA NEW GUINEA: Madang Prov.: Madang. 8 September 1964. Collector unrecorded. AMS R111666. First record for province and range extension of ca. 120 km from populations in the Central Highlands (Richards and Price, 2004) and 300 km from population at Wamangu, East Sepik Province (Dahl et al. 2009).

Nyctimystes fluviatilis. PAPUA NEW GUINEA: West Sepik Prov.: Parkop, Torricelli Mts., 3.42457°S, 142.51866°E, 416 m elev. 14 May 2005. F. Kraus. BPBM 23251–52; 3.2 km SSE Mt. Sapau summit, Torricelli Mts., 3.39329°S, 142.52826°E, 550 m elev. 18–25 May 2005. F. Kraus. BPBM 23253, 23256–59, 23263–65; Wilbeite Village, Torricelli Mts., 3.416667°S, 142.116667°E, 10 June 1988. T. Flannery. AMS 130396. Western Prov.: Kavorabip, 5.133333°S, 141.11666667°E. 22 August 1972. F. Parker. MCZ 110312–13. First records for country and range extensions of ca. 450 km to E and 330 km to SE, respectively, from the type locality along the Idenburg River (Zweifel 1958).

Nyctimystes zweifeli. PAPUA NEW GUINEA: Chimbu Prov.: Doido, 6.55°S, 144.83333°E. 14 April 1985. S. Donnellan. AMS R114802, 114804; Southern Highlands Prov.: Bobole, 6.20ºS, 142.76666667ºE. October 1985. S. Donnellan. AMS R132353–58. First records for each province and range extensions of 360 km ESE and 150 km SE of the type locality at Telefomin (Tyler 1967).

Hypsilurus hikidanus. PAPUA NEW GUINEA: Chimbu Prov.: Toromambuno, Mt. Wilhelm, 5.8442028ºS, 145.1018018ºE. 4 July 1955. J. L. Gressitt. BPBM 2693–96. First record for country and range extension of 850 km to the east from type locality at Wissel Lakes (Manthey and Denzer 2006).

Hypsilurus longii. SOLOMON ISLANDS: Isabel Island: Alu Alu village, 8.3ºS, 159.55ºE. 23 February 1991. H. Parnaby and I. Aujare. AMS R137241; Kaipitu River, near Alu Alu village, 8.3ºS, 159.55ºE. 24 February 1991. H. Parnaby and I. Aujare. AMS R137243; Makira Island. 20 November 1987. G. Mengden. AMS R127290; Makira Island: Sgsgna village. 16 November 1987. T. Flannery. AMS R130465. New island records that extend the range of this species to the southern end of the Solomon Islands. Previously reported only from Bougainville at the NW end of the chain (Manthey and Denzer 2006). McCoy (2006) inferred that the Isabel Island specimens, which he had not seen, belonged to this species based on their large size. I confirm that presumption.

Hypsilurus macrolepis. SOLOMON ISLANDS: Choiseul Island: Malangona, 7.049ºS, 156.778ºE. 14 March 1964. P. Temple. BPBM 2488. New island record and range extension to NW from Santa Isabel Island (Manthey and Denzer 2006).

Hypsilurus magnus. PAPUA NEW GUINEA: Central Prov.: Moitaka, Port Moresby. September 1985. S. Donnellan and K. Aplin. AMS R122448; Madang Prov.: Warius River, 5.9592435ºS, 145.86632ºE, 400 m elev. 31 August 1987. C. P. Kendrick. BPBM 21635. Morobe Prov.: Tekadu, 7.664855ºS, 146.5638586ºE, 400 m elev. 20 October 1996. A. Allison. BPBM 13171. Southern Highlands Prov.: Bobole, 6.20ºS, 142.76666667ºE. October 1985. S. Donnellan and K. Aplin. AMS R122427–29, 122441, 122476; Namosado, 6.25ºS, 142.783333ºE. 1985. S. Donnellan and K. Aplin. AMS R122433–40, 122442–46, 12249–51, 122461–70; Fogamaiyu, 6.51666ºS, 143.083333ºE. December 1985. S. Donnellan and K. Aplin. AMS R122471–75; confluence of Libano and Hegigio rivers, 6.3990666ºS, 142.9761333ºE, 250 m elev. 4–6 August 2003. A. Allison. BPBM 28231–35. Western Highlands Prov.: Manjim, Ganz River, 5.53333ºS, 144.483333ºE. 16 July 1954. Troughton and Campo. AMS R14751–57; Jimi River, 5.35ºS, 144.3333ºE. 21 July 1954. Troughton and Campo. AMS R14761–62; Baiyer River, 5.55ºS, 144.0ºE. 14 August 1969. Collector unrecorded. AMS R28690; West Sepik Prov.: Trefas Village, 5.9 km N, 7.3 km E of Utai, 3.333ºS, 141.651ºE, 320 m elev. 22 September–23 October 1996. A. Allison. BPBM 23159, 23165, 23172; Menawa River, 8.4 km N, 11.4 km E of Utai, 3.312ºS, 141.688ºE, 560 m elev. 24 September 1996. A. Allison. BPBM 23161–62. First records for country (Manthey and Denzer 2006), suggesting the species is widely distributed across most of New Guinea.

Hypsilurus schultzewestrumi. INDONESIA: Papua Prov.: Bokondini, 40 km. N. of Baliem Valley, 3.63ºS, 138.6ºE (datum unknown), 1400 m elev. 18 November 1961. L.W. Quate and S. Quate. BPBM 3296; PAPUA NEW GUINEA: Chimbu Prov.: Goglme, 5.93333ºS, 145.03333ºE. No date. J. Hope. AMS R29126–28; Eastern Highlands Prov.: Roka Estate Village on Goroka-Daulo Pass Road, 6.05S, 145.4E. No date. A. K. Lee. AMS R64740–71;

Koge, 6.10ºS, 145.01666ºE. 16 October 1965. F. Parker. AMS R68895; Irumbafoi, 6.23333ºS, 145.26666ºE. 13 July 1964. Collector unrecorded. AMS R86887; Enga Prov.: Yaramanda, West Baiyer Valley, 5.61666ºS, 143.916666ºE. 22–28 August 1955. R. N. H. Bulmer. AMS R14849–50; Madang Prov.: Fungoi, Kaironk Valley, Schrader Mts., 5.333333ºS, 144.41666667ºE. 14 December 1963–1 January 1964. H. G. Cogger. AMS R21190–91, 23039, 24328–30; West Sepik Prov.: Telefomin, 5.136775ºS, 141.633333ºE. 30 August 1963. P. Temple. BPBM 3858. First is new country record; remainder are new provincial records. Previously known with certainty only from type locality at Nondugl, Western Highlands Province, Papua New Guinea (Manthey and Denzer 2006).

Snakes

Toxicocalamus stanleyanus. MADANG PROVINCE: between Hinihon and Reinduk, 1000 m elev. 24 March 1974. G. B. Opit. BPBM 5711. First record for province; nearest record is Gulf Province ca. 300 km away on S side of Central Dividing Range (McDowell 1969; O'Shea 1996).

Acknowledgments.—I thank R. Sadlier for open access to the collections at Australian Museum, G. Zug for same at USNM, and J. Rosado for loan of specimens; J. Anamiato, A. Aralu, T. Bulu, A. Buntapeko, M. Ewai, D. Gibson, B. Iova, D. Iova, E. Lonpulpagetuna, D. Matalo, F. Paisparea, M. Paisparea, G. Petawi, F. Tatabe, and M. Yewa for providing logistical or field assistance; the PNG National Museum and Art Gallery for providing in-country collaborative assistance; and the Department of Environment and Conservation, National Research Institute, and Southern Highlands provincial government for research permits. This research was supported by National Science Foundation grant DEB-0743890, and work in the AMS was supported by grant #020954 from the Global Biodiversity Information Facility Secretariat. This is contribution 2010-004 from the Pacific Biological Survey at the Bishop Museum.

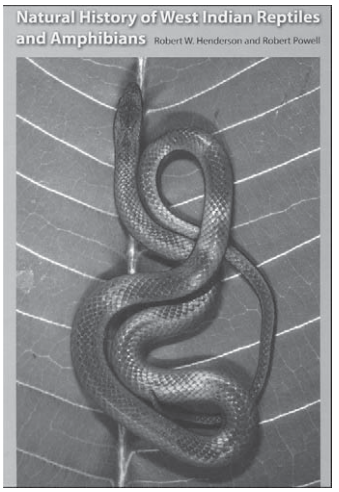
Cover Images for *Herpetological Review*

We are looking for photographic images to appear on future covers of *HR*. To be considered, preferred images should have the following qualities:

- Should be technically superior photographs (e.g., composition, lighting, etc., should be excellent; subject must be in focus).
- Should be taken in vertical format, or, if in landscape format, permit cropping to achieve a vertical orientation.
- Should be based on film or digital media; if the latter, the native resolution must be sufficiently high to permit cropping and/or enlargement to print publication quality (many "point-and-shoot" digital cameras do not produce image files with sufficient resolution for print publication).
- Preference will be given to images that depict poorly known species. These could include recently described taxa or species for which a color illustration has never been published.
- Preference will be given to images that communicate some aspect of the biology of the organism (e.g., predation, feeding, courtship, crypsis).



Images for consideration should be submitted as low-resolution jpg or pdf files. Do not send full resolution images via email. All submissions or questions should be directed to the Editor (HerpReview@gmail.com).

The West Indies are home to more than 6.3% of the world's reptile species, including more than 600 species found nowhere else on earth (Hedges 1996). This extraordinary diversity, combined with the presence of herpetology's best-known example of adaptive radiation (*Anolis* lizards) and the region's proximity to the United States have made the West Indies a Mecca of herpetological research for over a century. When it comes to comprehensive book length treatments of this herpetofauna, West Indian herpetologists have tended to prefer substance over style. For nearly two decades, the best example of this was Schwartz and Henderson's (1991) *Amphibians and Reptiles of the West Indies: Descriptions, Distributions, and Natural History* (hereafter S&H), which makes up for a lack of illustrations with comprehensive species descriptions, dot maps, and natural history notes for every species of West Indian amphibian and reptile. S&H remains one of the most impressive compendia ever published on a regional herpetofauna and has served a foundation for herpetological research in the West Indies for nearly two decades.

Henderson and Powell's (2009) (hereafter H&P) new compendium on the natural history of West Indian amphibians and reptiles expands the foundation provided by S&H, and provides an impressive resource for the next generation of West Indian herpetological research. Although it shares S&H's emphasis on style over substance (there are few illustrations), it is much more than a mere rehash of S&H's classic work; instead, H&P focus primarily on updating and expanding the natural history information included in S&H. H&P also provide the first comprehensive assessment of the conservation status of reptiles and amphibians—a key contribution given the relatively small ranges of many of the region's endemic species. Along the way, H&P nearly triple the number of references contained in S&H, a testament to H&P's scholarship and the expanding body of literature pertaining to the natural history, ecology and conservation of West Indian herps (over 2600 references in H&P versus 883 in S&H).

Henderson and Powell lead off with an insightful review of the West Indian herpetofauna and efforts to study it, including a wide-ranging consideration of this fauna's future. The "Where We are Today" section includes an excellent summary of the history of West Indian herpetology. H&P also use informal meta-analyses to illuminate the uniqueness of the West Indian herpetological fauna and to highlight the taxonomic imbalance of previous work on West Indian herps; some taxa have enjoyed sustained natural history research while little is known of many other taxa beyond their existence. Following up on this observation, H&P's introduction closes with a discussion of the future of West Indian herpetology that serves as both a roadmap for future research and a call to arms for the herpetological community.

One of the most important features of H&P is the information it contains on the conservation status of West Indian reptiles and amphibians, including a comprehensive summary of the various threats facing this fauna. Although the West Indies are home to hundreds of narrowly distributed endemic species living in heavily disturbed environments, conservation efforts are focused almost exclusively on a few particularly charismatic species like rhinoceros iguanas, boas, and racers. One reason for this is that the tenuous status of many lesser-known West Indian reptiles and amphibians has been overlooked by the broader community of conservationists. H&P begin their efforts to overcome this oversight with an extensive review of the literature that considers the impact of threats like introduced species, habitat loss, accidental and intentional killing by humans, climate change, natural disasters, non-native parasites, pollution, loss of prey sources, human overpopulation, and commercial exploitation.

The remainder of the book is composed primarily of species accounts (arranged alphabetically and by Linnaean rank). The structure of the species accounts in H&P differs substantially from those found in S&H. Gone are range maps, physical descriptions of species, type specimen and locality data, and discussion of the systematic relationships among species. Missing from both books are images of species and characterization of calls for amphibians, although H&P point to other resources for these data. Information on natural history, meanwhile, is greatly expanded. Material new to this volume includes impressive species-by-species conservation summaries including IUCN, CITES, or other assessments as well as any relevant literature on specific threats to each species (e.g., habitat loss, active hunting/extermination by Amerindians or current residents, etc).

H&P contains accounts for 152 species not recorded in S&H (an increase of 26%), reflecting both increased interest in West Indian Herpetology as well as a shift in taxonomic methods over the last two decades. Unlike S&H, however, subspecies are only rarely discussed and phenotypic or ecological distinctions among subspecies are not addressed. The content of each species' Natural History section varies depending on the available references. Headings include: abundance, activity, behavior, biomass, competition, diet

and foraging, dispersal, growth, home range, movement, parasites, population size and density, predation, reproduction, sex ratio, size, tail autonomy, thermal biology, as well as ecomorphology information for anoles. H&P draw upon years of field experience, an exhaustive literature review, and an international network of West Indian herpetologists to compile each detailed and rigorously researched species account.

We have only a few minor complaints with H&P, including unqualified use of generalizations and anecdotal field observations, the absence of a small number of natural history references, and the potential that geographic variation in the natural history of species is overlooked by focusing exclusively on taxa recognized at the species level. The inclusion of anecdotes and antiquated natural history observations is a double-edged sword. Although we agree with H&P's comprehensive approach, we caution readers against over-interpreting information that is presented in accounts without bias or explanation. Anecdotal claims like the suggestion that *Anolis strahmi* is "[n]ot easily alarmed," for example, are often oversimplifications. The *Bothrops caribbaeus* account cites Tyler (1849) on envenomation: "If not bitten in a large blood vessel, little danger exists for a loss of life if a mixture of lime juice, rum, and salt is imbibed, followed by intoxication and sleep." Although amusing to the experienced herpetologist, this account could easily be misconstrued as factually accurate information by the uninitiated. Although this is an extreme example of the potential problems with anecdotal information, it might be useful to include some evaluation of poor or unreliable references.

We conducted basic literature searches for natural history information on 73 taxonomically dispersed accounts; this work confirmed the thoroughness of H&P's scholarship. In most cases H&P cited every reference to a species that we could find, in many cases supplementing the references we were able to find with somewhat more obscure references that could not be located with internet-based searches. The few neglected references we did find tend to originate from journals outside the purview of practicing herpetologists; for example, H&P missed a note on Burrowing Owl predation on *Typhops hectus* from the Journal of Raptor Research (Wiley 1998). In other cases, individual species accounts did not reference relevant material that is cited elsewhere in the volume. Species accounts for *A. porcatus* and *A. allisoni*, for example, should have included some mention of the character displacement that Schoener (1977) reported in central Cuba.

Although it may be asking too much, including some information on taxonomic relationships among species would have been a useful addition. With such information, it might be possible to extract some suggestive information about the natural history of recently described or relatively poorly known species by examining accounts of closely related taxa. For instance, the account for *A. marron* contains very little detail. This species was elevated to species status from populations previously placed in *Anolis brevirostris* (Arnold 1980). Although specific natural history studies since this elevation are lacking, the close evolutionary relationship of these species suggests some overall similarity between the two.

H&P's book is a monumental contribution to West Indian herpetology. Its comprehensive coverage and the level of detail afforded each species is virtually unparalleled among references for diverse herpetofaunas. H&P is a necessary companion to S&H for any herpetologist working in the West Indies. Henderson and Powell's new volume provides much more comprehensive natural history information for the West Indies than its predecessor, although S&H remains important because of its dot maps, type records, and morphological descriptions. We can now look forward to the forthcoming field guide (S. B. Hedges, *in prep*.), complete with range maps and color photographs for every West Indian species, which will complete an important trinity for West Indian herpetology.

Timber Rattlesnakes in Vermont and New York—Biology, History, and the Fate of an Endangered Species, by Jon Furman. 2007. University Press of New England (www.upne.com). Softcover. xiii + 207 pp., 8 pp. pls. US $24.95. ISBN 978-1-58465-656-2

WILLIAM S. PARKER
1219 Mapleview Drive, West Point, Mississippi 39773, USA
e-mail: bparker@muw.edu

What better way to demonstrate obstacles and solutions to conserving and saving a sometimes misunderstood endangered species than to document the process in a readable fashion? Conservation can be particularly difficult with long-reviled and late-maturing species such as venomous snakes, which engender an innate response of fear and repulsion in many people. Herpetologists are thoroughly familiar with common negative attitudes among the general public toward snakes, especially venomous ones (but you'd never know it if you visit a reptile house at any zoo). Furman

approaches this dilemma in some detail, contrasting the knowledge, experiences, attitudes, and behavior of professional biologists and conservationists with those of outdoors laymen and snake hunters. This has resulted in a book of intimate detail including documentation of extensive field trips by the author guided by those doing field research specifically on conservation and population biology of Timber Rattlesnakes, plus in-depth interviews with 'the other side,'i.e., individuals and their family members who have historically harvested (killed) thousands of these animals for sport, bounty, or some valued feature of their bodies.

Timber Rattlesnakes were once found across much of the eastern United States east of the Mississippi River but are now exterminated or found more often in geographically restricted areas. Furman's book covers the current northern limit of the species' range in the east, focusing on a pocket encompassing three counties in New York and one adjacent county in Vermont where bounties on this species over a 75-year span led to elimination or decimation of most populations. Since the bounties were legally discontinued by state laws in the 1970s, many of these populations have recovered to some extent. The snake's recovery process has been followed and enhanced for the past 40 years by a handful of dedicated biologists and concerned citizens.

Furman's first chapter is the longest and most comprehensive, providing a broad introduction to Timber Rattlesnake anatomy, foraging, prey, predators, habitats, dens, movements (including swimming), body temperatures, basking areas, aggressive behavior, use in church rituals, mating, and longevity. For these features, he draws on an extensive recent literature and provides detailed sources (accumulated at the end of the text) which include quotes and comments from current researchers. Answered are questions about the complex structure of the jaws, fangs, and facial pits and their complex functioning in the lives of these animals; the significance of the rattle and its maximum number of segments; and the age at sexual maturity and frequency of litter production by the late-maturing females, some of which may reproduce only once every five or six years, depending upon food availability.

Chapter 2 is short and concerns mainly maximum body sizes, discussing the uncertainty about whether individuals have ever reached six feet in total length. Earlier workers may have included the rattle in their measurements and may also have stretched the snakes to try and achieve record lengths. Perhaps a six-footer is possible but current workers seldom find individuals as long as five feet.

Snakebite is the focus of the longer chapter 3 and includes statistics on 'dry' bites, constituents of the venom, symptoms, and treatment of bites based on consultation with noted experts. Furman includes case studies of individuals he has known personally, detailing the circumstances of their bites, the treatments and consequences including lasting damage, both psychological and physical. This is one of the most pertinent sections of the book for those who are concerned about avoiding or dealing with a bite from one of these snakes.

Rattlesnake fossils go back as far as the Miocene and those of Timber Rattlesnakes back nearly a million years. The species was once more abundant at the northern limits of its range but has been exterminated from eastern Canada, Rhode Island, Maine, and much of New York State (Chapter 4). Furman documents some of the most egregious killings, sometimes numbering in the thousands of snakes. Even our early presidents Jefferson and Madison, traveling together on an outing in May 1791, shot two rattlesnakes near "Fort George" within the area covered in Furman's book (Ketcham 1971). However, well over 100 dens still exist in southern New York and a few dozen in the other northeastern states. Conservation efforts, elimination of bounties, and state endangered species listings have mostly assured protection and rejuvenation of many of these populations. Chapter 5 addresses this transition during the 1980s and 1990s in New York and Vermont as the species was listed in 1983 as threatened in New York and in 1987 as endangered in Vermont.

Chapter 6 is a fascinating one, tracing the history of bounty hunting in New York and Vermont over the years and documenting the dollar amounts of the per-snake bounty, which worked its way up from 25 cents in 1896 to five dollars in each of New York's three timber rattlesnake counties by 1956. Bounties were discontinued in both states in 1971, with the last payment in 1973 in New York. Resolutions on the bounty systems by the County Board of Supervisors in the three New York counties are a valuable part of the historical record (heretofore undocumented) and are included in Furman's source notes. Higher bounties in New York encouraged some collectors to bring snakes or snake parts from other states, including Vermont, to get the larger payments. Since termination of the bounty system, snake numbers have recovered to perhaps 8–10,000 statewide in New York, and observers have noted greater numbers of the largest individuals in recent years.

Furman's last three chapters are each devoted to one of the famous (or infamous) rattlesnake bounty hunters and their families in Vermont and New York. Furman personally spent many hours interviewing these now elderly (or deceased) individuals to gain insight into why they started killing and/or collecting rattlesnakes and how many they may have killed over the years (thousands) for rather substantial annual profits in several cases. Much as we would like to completely deplore their behavior, some of these individuals performed at least a few redemptive services. These included enabling the sale of family land in Vermont which included a rattlesnake den for protection by The Nature Conservancy. One of the bounty hunters performed crude experiments on feeding and hibernation but hosted "snake roasts" for local social gatherings, while others boiled rattlesnake fat and used the resulting oil as a medicinal ointment for burns, joint pains, and such.

The book finishes up with a short chapter called 'Rays of Hope' which reemphasizes the elimination of bounties, the establishment of formal endangered status, and the willingness of many residents to refrain from killing 'nuisance' snakes and instead to cooperate with conservationists to relocate them unharmed to other places nearby. These workers also give frequent public talks about the nature of the snakes and the need for their conservation. Furman relates the experiences of conservationists and professional biologists in New York who continue to struggle with pressures from real estate developers and industrialists wanting to destroy critical habitat for Timber Rattlesnakes, and who often testify in court cases.

The book is enhanced by individual photos of biologists and former bounty hunters, plus color photos of timber rattlesnakes. There are also sobering color photos of a snakebite victim's hand. Excellent color maps by W. H. Martin of the species' former and current distributions are also presented. An extensive nine-page

cross-reference index concludes the work.

I have had the good fortune to have spent many hours in the field and at conferences with the author and many of the biologists and colleagues whose work forms the crux of this book. Over the years, I have been overwhelmed with their knowledge and dedication to the welfare of this most complex and sophisticated species of snake. Several have contributed their entire professional careers to this species and have expended their own funds to study the species or buy lands for its protection. My appreciation for the snakes themselves has also grown immensely after seeing their quiet and retiring nature in the field. Furman's book is well worth the read as it captures this species' natural history and many insights about nature, enabling conservation for the future through solid and intimate knowledge of Timber Rattlesnakes.

The Biology of the Coccidia (Apicomplexa) of Snakes of the World, by Donald W. Duszynski and Steve J. Upton. 2009. Published by the authors (available at: https://www.createspace.com/3388533). 422 + i–viii pp. Softcover. US $70.00. ISBN 97814486179.

CHRIS T. McALLISTER
RapidWrite, 102 Brown Street
Hot Springs National Park, Arkansas 71913, USA
e-mail: drctmcallister@aol.com

This is an excellent and much welcome summation of all of the coccidian parasites (Protista: Apicomplexa) of the suborder Ophidia (= Serpentes) by two well-known parasitologists who have had a life-long interest in and are the world's foremost authorities on the subject. The book has already received favorable reviews (see Agnew 2010; Graczyk 2010; Modrý 2010) as well as positive reviews provided within the text by six knowledgeable parasitologists with experience in the study of coccidia (see pp. iii–iv). I will not stray too far from those previous reviews except to say I will provide an equally fair assessment but with some balance.

The content includes 13 chapters, literature cited, glossary (and list of abbreviations), and index. One of its major strengths is the extensive literature cited section which spans some 27 pages (>6% of the book). If ever anyone needed to locate vague or hard to find citations on the coccidia of snakes, they need only check this compilation. The book is an easy read for herpetologists and parasitologists alike, and others (zoo biologists and veterinarians) will find it a valuable asset to their personal library.

The introductory chapter deals with some general aspects of snake and coccidian biology, as well as several terms (in bold face) relating to the subject and helpful to the layperson. It also provides figures of Nomarski interference-contrast photomicrographs of oocysts of three genera and six species of coccidia for comparative purposes. A minor error appears in the figure legend (Fig. 1.1 F); I believe the oocyst of *Isospora wilsoni* from *Tantilla gracilis* is from the symbiotype host snake collected from Arkansas, not Florida (see Upton et al. 1992, Figs. 5–6). Inclusion of Fig. 1.2 on phylogenetic relationships among the major taxa of snake families (cladogram) strongly suggests that a great deal of knowledge on snake coccidia remains to be discovered as only select members of seven of 17 (41%) snake families have been previously reported to harbor species of coccidia. In other words, about 235 species of snakes in 10 families have **never** had coccidian parasites reported from them, not to mention many others from the other seven families!

Chapter 2 provides more detailed information on the general systematics and life-cycles of coccidia. It is very well done and shows the reader that coccidia have varied, somewhat complex life-cycles, including direct or indirect ones that include both sexual and asexual reproduction. Development of coccidia occurs within various host cell types of the vertebrate intestinal tract or related structures and some (those with indirect life-cycles) even utilize an intermediate host. Several figures within this chapter enhance our understanding of these life-cycles and are a must read for those needing to know details of the four major types of life-cycle strategies employed by snake coccidia. There are some minor typos on line 2 of Fig. 2.4 (A) and font sizes are larger but the photomicrographs of the *Caryospora* spp. are superb.

Chapter 3 covers techniques, including collection, storage, and identification of coccidia. This is another very important chapter in the book. It helps teach the non-specialist (and herpetologists and veterinarians with little experience) to process hosts for coccidia as well learning detailed methods for the isolation of oocysts. However, be forewarned that some cost is involved in acquiring the materials necessary for such study and practice is recommended before wasting important specimens for which you have limited snake fecal material. One thing not said on page 24 is that some commercial microscopic coverslips do not adequately allow oocysts to adhere to their surface via the flotation method. So, if you have enough material, do some practice runs using the various types of coverslips. And, those fortunate enough to spend some time on a brief sabbatical in a laboratory with an expert will certainly be trained thoroughly enough to be on their own. This all takes a lot of practice and many herpetologists have soon learned that collecting the snake, getting its feces, placing an equal aliquot in vials of 2.5% (w/v) aqueous potassium dichromate, and then shipping it overnight to a trained specialist, may be the best way to go. But even that has some limitations and requires a previously understood collaboration. The chapter ends with a discussion of taxonomic terms that are found throughout the book and professional quality line drawings (Fig. 3.1A–D) showing oocyst morphological

structures that should be measured and documented for species identification and formal description.

The following eight chapters (Chapters 4–11) deal with the individual major snake taxa (families, genera, and species) harboring coccidia in a useful, easy to follow, standardized format. The arrangement of taxa is mostly according to the system given by Uetz (2007) via the JCVI/TIGR Reptile Database (http://www.reptile-database.org/); however, the reader should be warned that some snake taxonomy has been in a state of flux and has changed since the book was written and may be expected to change even further. And for some published binomials that have undergone recent nomenclatural changes, the authors attempt to report both the old and new names, but they do so inconsistently (i.e., *Python* vs. *Broghammerus*; *Elaphe* vs. *Pantherophis*). In addition, *Eimeria desotoensis* was described from *Virginia striatula* from Arkansas and Texas (i.e., city of DeSoto is type locality), not just Arkansas (see p. 86, but corrected on p. 116). And, the symbiotype host of *Eimeria rhombifera* is *Nerodia rhombifer*, not *Nerodia cyclopion* (see p. 109 and check type locality). Some of the taxonomic confusion is abated by thoroughly cross-referencing in the index, but some host taxonomic confusion and different common name usage still occurs. And most unfortunately, other errors (mostly typos) become exponential in these chapters (see criticism below).

I must admit that it is somewhat troubling that the authors overlooked many of the typos contained within the book (primarily in Chapters 4–11, pp. 31–302). Some of these errors appear to be typical word.doc problems (and possibly pdf errors), and with two authors writing separately, hidden codes may have leaked into the final document without them knowing. These errors (typos) include, but are not limited to: misspellings, lack of required italicization, letters left out, extra letters/words, different font sizes, transpositions, etc. Examples include misspellings: species inquirendae at least 12 times (pp. 34, 40, 41, 44, 144, 197, 200, 210, 265, 271, 288 [twice]), the specific or subspecific epithets *reticulatus* (misspelled *reticulates* on pp. 40 [twice], 44 [twice], 338 [twice], 345, 366 [three times], 368, 411), *obsoleta* (misspelled *obsolete* on pp. 146, 242, 260 [twice], 328, 341–342, 365), *lineata* (misspelled *lineate* on pp. 148, 156, 277, 365), *catenifer* (misspelled *cantenifer* on pp. 145, 277, 334, 339, 356), *vulpina* (misspelled *vulpine* on pp. 260, 337 and *vupina* on p. 335) authors Freed (misspelled Free on pp. 126, 199), Lainson (misspelled Lanison on pp. 136–137) and Ovezmoukhammedov (misspelled Ovezmoukhammedova on pp. 349 and 390 [three times]).

Other corrections needed are to include the hosts *Agkistrodon piscivorus* in Table 7.1 and *Masticophis flagellum* in Table 9.2. The misconception that no species within the family Leptotyphlopidae (blind snakes) have been examined for coccidia (p. 220) is incorrect as McAllister et al. (1995, p. 63) examined four specimens of *Leptotyphlops* (=*Rena*) *dulcis* from New Mexico (n = 1) and Texas (n = 3) and none were infected with coccidia. On a lighter side, the shakes on (p. 109) should be snakes, the Lind Snakes (p. 219) should be Blind Snakes, and the western coachwhip "terrapin" (pp. 261, 342) should, of course, be a snake.

The authors report that there are about 4000 known species of parasitic protists in six major taxonomic groups that infect a wide variety of vertebrates and invertebrates. Of these, only 156 coccidians of snakes are considered valid species and only 208 of 3180 (7%) extant snake species have been examined for and reliably reported to harbor coccidia. This is especially true about the 55+ unknown species of *Sarcocystis* previously known from snakes and reported simply as *Sarcocystis* species inquirendae. Part of this enigma lies in the fact that it is impossible to determine *Sarcocystis* species definitively without experimental transmission studies because the sporocysts found in the feces of the definitive host, are very similar in size and morphologies (Duszynski and Upton 2009; McAllister et al. 1995). In an attempt to abate this problem, the authors make several pleas (Chapters 9, 13) for cooperation between herpetologists and parasitologists to work as equal partners "*if we are ever to have an inkling of the true biodiversity of snake parasites*…" and "*to be more receptive to working together*….". As someone who has collaborated on snake coccidia with academic herpetologists, including those with state and federal agencies and employed by zoos (McAllister et al. 1993, 1995, 1996), I could not agree more.

The authors provide descriptions of four new species of coccidia (**ii and Chapters 5, 7, 9) to include one eimerian (p. 64), one caryosporan (p. 200), and two *Sarcocystis* spp. (pp. 225, 236). One description, however, contains a serious typo (Chapter 5, p. 64) of the new species of *Eimeria* from *Lampropeltis getula californiae*. The spelling of the specific epithet as first given is misspelled: *Eimeria lamporpeltisgetuli* should be *E. lampropeltisgetuli* but it must stand until corrected in a future justified emendation under Article 32.5 of the Code (Ride et al. 2000). Interestingly, on pages 85, 147, 154, and 414, that specific epithet is spelled correctly but incorrectly twice (pp. 331, 350).

The photomicrographs and line drawings are top-notch and improve the overall message of the book. They allow the reader to employ a quick and user friendly comparative approach when examining different morphologies among similar oocysts of the various coccidian taxa of snakes. However, the following five figures of sporulated oocysts appear to be photomicrographs, not line drawings, as suggested in their respective figure legends (Figs. 4.1C, 5.6, 5.35, 5.98, 7.1G). The book cover includes a nice black and white photomicrograph showing numerous endogenous developmental stages of an *Eimeria* sp.

Chapter 12 provides strategies for management and therapy of reptilian coccidiosis, including the more serious disease, cryptosporidiosis. This chapter should be of special interest to veterinarians and zoo personnel who treat and house sensitive species. It includes very detailed information about a proprietary website, Veterinary Information Network (VIN; http://www.vin.com), where veterinarians from all over the world discuss common issues, problems, drugs, and treatment regimens (see Table 12.1). Ultimately, this will allow veterinarians immediate access to what therapies have worked for others and to access appropriate references.

The book ends with Chapter 13 in which the authors ask the question "*so what does all of this mean*?" The authors provide two very important tables in this chapter (13.1–13.2), although they contain numerous typos (pp. 320 [five], 328, 331, 333 [two], 334–335, 337 [three], 338 [five], 339 [two], 340–341, 342 [three], 343. 345, 346, 349, 350 [two], 351 [two], 353 [two], 356). Most importantly, these tables allow the reader to quickly see an alphabetical list of all coccidian parasites recorded from all snake hosts and a host-parasite index (through 2008). This will be indispensable to those needing to cut-to-the-chase if they have a new host and/or distributional record, or even better, a new species of coccidian.

Two additional tables (13.3–13.5) may be directed toward the more serious snake coccidian researcher as they cover cross-transmission studies, pathologies, and endogenous developmental stages from snakes. Needless to say, there are several typos in these tables (i.e, original is misspelled orignal 12 times!) and other typos are found on pp. 362, 365 (three), 366 (three), 368, and 370 (two).

It is abundantly evident that these authors devoted much time and energy to preparing this work, reviewing hundreds of references as well as spending several years developing a readable text for specialists and non-specialists alike. Drs. Duszynski and Upton should be commended for taking on this task effectively and covering global aspects of the biology of the coccidia of snakes. On the other hand, there are too many typos and errors and hopefully those will be corrected if a second edition is done. The $70 cost for a paperback may be a little out of line and could dissuade some non-specialists from purchasing a copy but all parasitologists and those herpetologists, veterinarians, and zoo biologists interested in snake coccidia should own a copy, regardless of the cost.

In summary and with these typographical concerns aside, the authors have done a yeoman's job in having in one place and in a highly organized manner, all of the world's literature on snake coccidia through 2008. First and foremost, they have produced a text that all parasitologists, but particularly those interested in coccidian biology, could use as a quick identification guide on species that they might recover from snakes. They have also produced a compilation that professionals, amateurs, and zoo herpetologists might use should they be interested in knowing anything about coccidia that could be infecting their snake of interest, research subject, captive specimen, or even pet. Lastly, they have produced a book that could be useful to small-animal veterinarians who examine snakes brought in as patients to their practice. As a whole, it is the gold standard and is much enhanced by the figures and layout. Undoubtedly, this book will become indispensable and THE source for any person remotely interested in snake coccidia, and I emphatically recommend it.

Acknowledgments.—I thank Rowland M. Shelley, North Carolina State Museum of Natural Sciences, Raleigh, for advice on emendations.

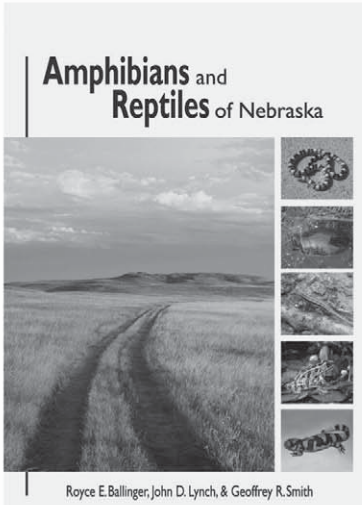
THE CHINESE ALLIGATOR

ECOLOGY, BEHAVIOR, CONSERVATION, AND CULTURE

John Thorbjarnarson and Xiaoming Wang

foreword by George B. Schaller

Illustrated throughout and featuring the most up-to-date biological information available, this volume is a complete overview of the Chinese alligator, a conservation and cultural icon.



"Drs. Thorbjarnarson and Wang are the ideal scientists—and truly the best qualified—to write this book. The story of the Chinese alligator is interesting on its own, and it primes those new to crocodilian conservation with what caused global declines of crocodilians and how crocodilian conservation has worked in many areas."—Lee Fitzgerald, Texas A & M University

288 pages, 94 illustrations, $85.00 hardcover

Amphibians and Reptiles of Nebraska

Royce E. Ballinger, John D. Lynch, and Geoffrey R. Smith

This is a 400 page authoritative review and reference to the 61 species of amphibians and reptiles known to occur within the boundaries of the state of Nebraska. It is the first comprehensive summary of Nebraska's herpetofauna since George Hudson's 1942 book on the same topic which covered the 56 species then known to occur in Nebraska. The book is well illustrated with 251 color photographs and 136 maps and diagrams. Documented with over 970 references, the text provides both an introduction for the amateur and a review for the professional herpetologist. With over 60 years of combined research experience on Nebraska amphibians and reptiles, the authors share many new records, observations, and insights on these fascinating animals.

Price is $45 plus shipping and handling ($5.00), check or money order.

Arizona residents add 8.3% state tax ($3.75)

Order direct from: Rusty Lizard Press, P.O. Box 68058, Oro Valley, Arizona, 85737

SSAR is pleased to announce the sale of

Roger Conant's Herpetological Library

Roger Conant (1909–2003) donated his herpetological library of more than 1200 books to SSAR to establish the **Roger Conant Endowment Fund** to support student research awards. This sale will take place during Autumn 2010. Many books will be sold for a set price, while others will be auctioned.

For more information about this sale subscribe to the Roger Conant Library mailing list at http://www.ZenScientist.com, or email SSAR@herplit.com

Roger's bookplate depicting two taxa of watersnakes named by him (copied above) is included in each book.

Information for Contributors

Herpetological Review is a peer-reviewed quarterly that publishes, in English, articles and notes concerning the study of amphibians and reptiles, as well as book reviews, commentaries, regional and international herpetological society news, and letters from readers directed to the field of herpetology. Articles reporting the results of experimental research, descriptions of new taxa, or taxonomic revisions are not published in ***HR***, but should be submitted to the ***Journal of Herpetology*** (see inside front cover for Editor's address). To submit a manuscript to ***HR***, please consult the SSAR webpage at:

<http://www.ssarherps.org/pages/HRinfo.php>

Reprints and Page Proofs

Reprints of notes or articles published in ***HR*** may be ordered through EZReprints (EzReprint@odysseypress.com), an online reprint ordering system. Authors will receive email notification as the issue goes to press. Page proofs are sent electronically to authors of all articles, book reviews, and obituaries, but are not sent for natural history notes or geographic distribution notes. Proofs are sent as pdf files approximately 2–4 weeks prior to publication.

Advertising

Herpetological Review accepts commercial advertising. Rates and copy information are available from the SSAR web page (http://www.ssarherps.org/pages/HRinfo.php).

Herpetological Review (ISSN: 0018-084X) is published quarterly (March, June, September, and December) by the Society for the Study of Amphibians and Reptiles at Central Michigan University, Department of Biology, 217 Brooks Hall, Mt. Pleasant, MI 48859, USA. Periodicals postage paid at Mt. Pleasant, MI 48859 and at additional mailing offices. All rights reserved. No part of this periodical may be reproduced without written permission of the Editor, except that authors and their agents are permitted to reproduce and distribute their own articles and notes. **POSTMASTER:** Send address changes to Breck Bartholomew, SSAR Publications Secretary, P.O. Box 58517, Salt Lake City, UT 84158. **MISSING OR DAMAGED ISSUE?** Please notify Breck Bartholomew, SSAR Publications Secretary (e-mail: ssar@herplit.com) for a replacement.

SSAR Publications

SSAR publishes seven different series: *Journal of Herpetology, Herpetological Review, Facsimile Reprints in Herpetology, Contributions to Herpetology, Herpetological Circulars, Herpetological Conservation*, and the *Catalogue of American Amphibians and Reptiles* (see below for CAAR details). SSAR members receive pre-publication discounts on all *Facsimiles* and *Circulars* and on volumes in the *Contributions* and *Herpetological Conservation* series. A complete pricelist of Society publications is available at: http://www.ssarbooks.com/.

Catalogue of American Amphibians and Reptiles

The ***Catalogue*** consists of loose-leaf accounts of taxa prepared by specialists, including synonymy, definition, description, distribution map, and comprehensive list of literature for each taxon. Covers amphibians and reptiles of the entire Western Hemisphere. Available for purchase from the SSAR Bookstore (http://www.ssarbooks.com/). Use the prices below to order back issues.

COMPLETE SET: NUMBERS 1 – 840		US $460
INDEX TO ACCOUNTS 1 – 400: Cross-referenced, 64 pages		$6
INDEX TO ACCOUNTS 401 – 600: Cross-referenced, 32 pages		$6
SYSTEMATIC TABS (Ten tabs to fit binder: "Class Amphibia," "Order Caudata," etc.)		$6
IMPRINTED POST BINDER (Note: one binder holds about 200 accounts)		$35
INCOMPLETE SET: NUMBERS	1 – 190	$75
	191 – 410	$85
	411 – 840	$320

To order: make checks payable to "SSAR" and mail to Breck Bartholomew, SSAR Publications Secretary, P.O. Box 58517, Salt Lake City, Utah 84158, USA (fax 801/453-0489). e-mail: ssar@herplit.com. Online orders at: http://www.ssarbooks.com/.

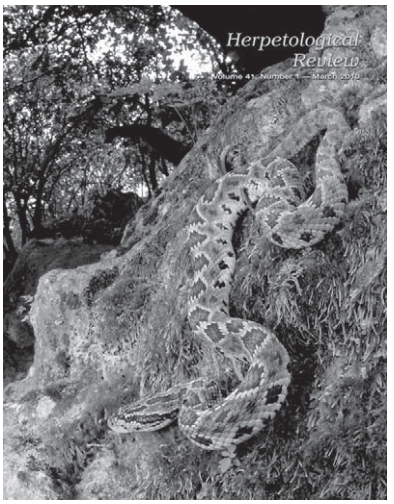
SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

www.ssarherps.org

The Society for the Study of Amphibians and Reptiles, the largest international herpetological society, is a not-for-profit organization established to advance research, conservation, and education concerning amphibians and reptiles. Founded in 1958, SSAR is widely recognized today as having the most diverse society-sponsored program of services and publications for herpetologists. Membership is open to anyone with an interest in herpetology—professionals and serious amateurs alike—who wish to join with us to advance the goals of the Society.

All members of the SSAR are entitled to vote by mail ballot for Society officers, which allows overseas members to participate in determining the Society's activities; also, many international members attend the annual meetings and serve on editorial boards and committees.

All members and institutions receive the Society's primary technical publication, the *Journal of Herpetology,* and its news-journal, *Herpetological Review*; both are published four times per year. Members also receive pre-publication discounts on other Society publications, which are advertised in *Herpetological Review*.



To join SSAR or to renew your membership, please visit the secure online ZenScientist website via this link:

Future Annual Meetings

2010 — Providence, Rhode Island, 7–12 July (with ASIH, HL)
2011 — Minneapolis, Minnesota, dates TBA (with ASIH, HL)
2012 — Vancouver, British Columbia, dates TBA (with ASIH, HL, WCH)

About Our Cover: *Crotalus lannomi*

In the summer of 1966, Joseph R. Lannom, Jr. traveled south from the U.S. to collect lizards along the west coast of Mexico for University of Arizona herpetologist Charles Lowe, but spent his evenings searching the roads for snakes. On the night of 26 June, he chanced upon a road-killed rattlesnake in the mountains of western Jalisco. That snake would turn out to be a new species, and the only one of its kind known over the next half century. Countless herpetologists—professionals and amateurs—ventured into the mountains of western Jalisco in the decades that followed, hoping to find another. But all who tried failed, and *Crotalus lannomi* seemed to take on near-mythic proportions—becoming a sort of "holy grail" of rattlesnakes.

In describing the new species, Wilmer Tanner (1966. Herpetologica 22[4]:298–302) noted the morphological similarity to the Sinaloan Long-tailed Rattlesnake, *C. stejnegeri*, another rare rattlesnake occurring farther north in the mountains of Sinaloa; both species were notably characterized by a long, slender tail, terminating in small rattles. Very recently, Jonathan Campbell and Oscar Flores-Villela described *C. ericsmithi*—the Guerreran Long-tailed Rattlesnake—from the Sierra Madre del Sur of Guerrero, roughly 500 km south of the type locality of *lannomi* (Campbell and Flores-Villela 2008. Herpetologica 64[2]:246–257). Campbell and Flores-Villela confirmed the alliance of *ericsmithi*, *lannomi*, and *stejnegeri* based on scalation, color pattern, and morphology. These three species occur in lower montane ecotonal habitats—transitional between lower-elevation tropical deciduous forest and upper-elevation oak or pine-oak forests. As a group, the long-tailed rattlesnakes also seem to be rare, with two of the three species (*ericsmithi* and *lannomi*) known only from single types, and the third (*stejnegeri*) known from only about a dozen specimens.

Over the last few years, field searches have intensified to locate populations of *Crotalus lannomi* in various mountain ranges in Nayarit, Jalisco, and Colima. In 2008, five specimens assignable to *C. lannomi* were found at two localities in the foothills of Colima, roughly 50 km from the type locality in adjacent Jalisco. This new material is reported in this issue of *HR* (Reyes-Velasco et al., pp. 19–25), adding significantly to our knowledge of the distribution and natural history of these elusive snakes.

The cover image depicts an adult female (61 cm TL) *Crotalus lannomi* recorded in the field in Colima. The photograph was a collaborative effort by **Ginny Weatherman**, **Jacobo Reyes-Velasco**, **Jason Jones**, and **Chris Grünwald**. The image was recorded with a Nikon D200 DSLR with a Tokina 10–17mm wide angle lens (17mm focal length, f/14, ISO 500), illuminated by a single Nikon SB800 flash with a Gary Fong dome diffuser. Reyes-Velasco is a student at the Universidad de Guadalajara; his herpetological field work in southwestern Mexico has resulted in a number of important finds (e.g., Reyes-Velasco et al. 2009. Herpetological Review 40:117–120; Reyes-Velasco and Mulcahy 2010. Herpetologica 66[1]:99–110). Weatherman, Jones, and Grünwald have spent considerable time in recent years traveling throughout Mexico; their efforts have yielded many significant herpetological finds.

SSAR is pleased to acknowledge the financial support of Ronald A. Javitch, Montreal, in making possible the publication of the cover image as well as the color figures in the Reyes-Velasco et al. article elsewhere in this issue.

SSAR BUSINESS

SSAR Henri Seibert Awards for 2010

The Henri Seibert Awards were initiated in 1992 to provide recognition for the best student papers presented at the annual meeting of the SSAR. To be eligible, the presented paper must be the result of research by the individual making the presentation. The research must have been conducted while the student was enrolled in either an undergraduate or graduate degree program. Please refer to *Herpetological Review* 28(4):175 and the SSAR website (http://www.ssarherps.org/pages/seibert.php) for recommendations to students entering the Henri Seibert Competition. Students entering the competition must be members of SSAR. The presentations will be judged by the SSAR student prize committee. One Henri Seibert Award of US $200 may be given in each of the following four categories: Systematics/Evolution, Ecology, Physiology/Morphology, and Conservation. Students may win a Henri Seibert award only one time. Please indicate the appropriate category for which you are applying on the abstract submission form. Announcement of winners will be made at the SSAR Business Meeting. All participants should be present at the business meeting. Contact Patrick Owen for further information, patrick.owen@uc.edu.

SSAR Silent Auction Donations

The SSAR announces the Fourteenth Annual Silent Auction to be held at the 2010 Joint Meeting of Ichthyologists and Herpetologists (JMIH) in Providence, Rhode Island, USA, 7–12 July. In previous years, items for the Silent Auction have been limited to frameable art. However, this year, we are glad to accept any herp-related donations, including but not limited to, frameable art (photographs, paintings, and line illustrations), books, music, glassware, jewelry, clothing and gift certificates for Providence area services/events during the meeting week. The SSAR Student Travel Committee organizes the Annual Silent Auction to raise money to fund the student travel awards to the JMIH. Your donations help provide opportunities for students to attend and present their research. If you are interested in donating an item or two (tax deductible for U.S. residents), please contact Matthew D. Venesky (mvenesky@memphis.edu) for more information.

NEWSNOTES

The J. Larry Landers Student Research Grant

The J. Larry Landers Student Research Grant is a Gopher Tortoise Council competitive grant program for undergraduate and graduate college students. Proposals can address research concerning Gopher Tortoise biology or any other relevant aspect of upland habitat conservation and management. The amount of the award is variable, but projects up to $2,000.00 have been awarded.

The proposal should be limited to four pages in length and should include a description of the project, a concise budget, and a brief resume of the student. Email submissions in word are preferred.

This is an excellent opportunity for undergraduate and graduate students to access funding for their projects. The deadline for grant proposals each year is the 15th of September. Please send submissions to: Bob Herrington, Chairperson, Research Advisory Committee, Department of Biology, Georgia Southwestern State University, Americus, Georgia, 31709, USA; e-mail: bherring@canes.gsw.edu.

Announcing a New Panamanian Field Station

La MICA Biological Station is located in El Copé, Coclé Province, Republic of Panama, near Omar Torrijos Herrera National Park. This area has been important for amphibian and reptile research and offers opportunities for any discipline of terrestrial biology. Much of the area is mid-elevation cloud forest with sites between 200 and 1440 m (station at 400 m). La MICA is situated on the Continental Divide, offering opportunities for studies in the Atlantic and Pacific versants.

La MICA Biological Station welcomes students, researchers, courses, and general tourists from around the world. Our facilities are under development, but currently offer a cabin, bathhouse, and soon a dormitory for 26 people with classroom. Logistics, including local transportation, food, guides/field assistants, and access to remote sites are all in place.

Nearly every position for employment is filled by local residents, thus providing them sustainable, conservation-oriented employment.

Visit the project website at http://www.lamica.org for more information.

Kansas Herpetological Society Annual Meeting

The Kansas Herpetological Society held its 36th Annual Meeting at MidAmerica Nazarene University in Olathe, Kansas, on November 7–8, 2009. Over 135 participants attended scientific paper sessions presented by scientists and students from across the nation. Featured speaker was Alexander Pyron (SUNY Stony Brook).

J. Kent Daniel, student at Pittsburg State University, received the 2009 Howard K. Gloyd/Edward H. Taylor Scholarship, honoring the memory of two great biologists with strong ties to Kansas.The 2009 Alan H. Kamb Grant for Research on Kansas Snakes was made to Mindy Walker, Rockhurst University. Paul Rodriguez, University of Nebraska, Omaha, was chosen as the twelfth recipient of "The Suzanne L. & Joseph T. Collins Award for Excellence in Kansas Herpetology." Emilie Blevins, Kansas State University, was presented with the George Toland Award for the best student paper given at the meeting. In 2010, the Society will meet at the Topeka Zoo, Topeka, Kansas.

MEETINGS

Meetings Calendar

Meeting announcement information should be sent directly to the Editor (HerpReview@gmail.com) well in advance of the event.

22–24 April 2010—57th Annual Meeting, Southwestern Association of Naturalists, Llano River Field Station, Junction, Texas, USA. Information: http://www.biosurvey.ou.edu/swan/annualm10.html

7–12 July 2010—Joint Meeting of Ichthyologists and Herpetologists (ASIH / HL / SSAR), Providence, Rhode Island, USA. Information: http://www.dce.k-state.edu/conf/jointmeeting/

21–24 July 2010—33rd Annual International Herpetological Symposium, Tucson, Arizona, USA. Information: http://www.kingsnake.com/ihs/

10–11 August 2010—Northeast Partners in Amphibian and Reptile Conservation (NEPARC) Annual Meeting, Acadia National Park, Maine, USA. Information: http://www.pwrc.usgs.gov/neparc/

22–26 September 2010—VIII National Congress of Societas Herpetologica Italica, Abruzzo, Italy. Information: shiabruzzo2010.iscrizioni@gmail.com

12–14 November 2010—5th National Symposium on the Ecology, Status, and Conservation of the Diamondback Terrapin, at Louisiana University's Marine Consortium (LUMCON) in Chauvin, Louisiana, USA. Hosted by the Diamondback Terrapin Working Group. Information: www.dtwg.org

CURRENT RESEARCH

The purpose of Current Research is to present brief summaries and citations for selected papers from journals other than those published by the American Society of Ichthyologists and Herpetologists, The Herpetologists' League, and the Society for the Study of Amphibians and Reptiles. Limited space prohibits comprehensive coverage of the literature, but an effort will be made to cover a variety of taxa and topics. To ensure that the coverage is as broad and current as possible, authors are invited to send reprints to the Current Research section editors, Joshua Hale or Ben Lowe; postal and e-mail addresses may be found on the inside front cover.

A listing of current contents of various herpetological journals and other publications is available online. Go to: http://www.herplit.com and click on "Current Herpetological Contents."

New Frog Family Found in South America

Studies over the last decade have brought to light evidence that the frog family known as "Leptodactylidae" for most of the 20th century is, in fact, wildly polyphyletic. Efforts to rectify this problem have resulted in the erection of numerous new families across Neobatrachia (including a much more exclusive Leptodactylidae). A recent phylogenetic study of a clade containing a subset of the former Leptodactylidae (named

Terrarana by the authors of the study and consisting of New World direct-developing frogs) revealed that one sample represented a deeply divergent and previously unrecognized lineage. Based on morphology, the sample had been assigned to the speciose terraranan genus *Pristimantis*, yet it was recovered as sister to the remainder of Terrarana. During subsequent searches of the locality in Guyana from which the sample in question was taken, one of the authors was able to procure more samples of this frog which they have described as a new genus and species, *Ceuthomantis smaragdinus*, and placed in a new family, Ceuthomantidae. An analysis confirming the placement of the new samples as belonging to a clade sister to the remainder of Terrarana also found a sister relationship between Terrarana and Hemiphractidae (marsupial frogs), illustrating that direct development was present in the common ancestor of these two groups of New World frogs. Furthermore, based on shared morphological characters, the authors were able to assign two other species of *Pristimantis* from Venezuela's Guiana Shield to the newly-erected family and genus. The discovery of this deeply-divergent lineage illustrates how much biodiversity remains to be discovered in the Guiana Highlands.

Heinicke, M. P., W. E. Duellman, L. Trueb, D. B. Means, R. D. MacCulloch, and S. B. Hedges. 2009. A new frog family (Anura: Terrarana) from South America and an expanded direct-developing clade revealed by molecular phylogeny. Zootaxa 2211:1–35.

Turtles, Salamanders, and Mammals Exhibit an Ancestral Mode of Germ Cell Specification

In most developing vertebrates, competent calls are either induced in the embryo to become specific tissues ("inductive mode;" seen in mammals and salamanders) or exist as a pre-determined germ plasm ("predetermined;" seen in frogs, snakes, and birds). These two different modes of cell differentiation are distinguished by the location of the primordial germ cells (PGCs) on the embryo (determined via in situ hybridization). In a few others (notably some Lepidosaura, including *Sphenodon*), PGCs are distributed all around the embryo (called the "circumferential pattern") and the mode of cell differentiation is unclear and may be either inductive or predetermined (or perhaps even both). The authors of this paper determined that turtles, unlike birds, exhibit the inductive mode of germ cell formation. Furthermore, they reconstructed the evolutionary history of germ cell specification mode in tetrapods. This analysis provided support to the hypothesis that inductive mode is the ancestral condition of tetrapods. Additionally, it was revealed that while germ plasm has evolved several times independently in tetrapods, reversion back to the inductive mode may not be possible. Finally, a change from inductive mode of germ cell formation to the circumferential pattern of PGC distribution occurred in the lineage leading to lepidosaurs.

Diverse Lines of Evidence Used to Delineate Species of Horned Lizards

Stemming from disagreement among researchers as to which characters are important in species delineation, the Coast Horned Lizard (*Phrynosoma coronatum*) of coastal California and Baja California has undergone several taxonomic re-arrangements over the years. The authors of this paper aimed to examine different lines of evidence and generate a hypothesis of species limits compatible with a modern, coalescence-informed understanding of speciation. Morphological (horn shape), genetic (mitochondrial and nuclear DNA), and ecological (environmental) data were procured for samples from across the distribution of the species. Morphological and ecological data were subjected to principal components analyses to identify geographically-cohesive groupings. Analyses of the genetic data were performed to examine evolutionary relationships (Bayesian analysis of mtDNA plus a topology test comparing the recovered phylogeny with an alternate, previously-published, morphologically-based phylogeny which recognizes four species) and to determine levels of gene flow across contact zones (nuDNA). As a criterion for species delineation, the authors looked for corroboration between independent lines of evidence. Based on DNA and ecological data correspondence, three species were recovered (one largely coincident with each of the states of Baja California Sur, Baja California, and California [from south to north]); this hypothesis was found to fit the genetic data far better than the alternate four-species hypothesis. Horn morphology separated the southern species; however, it was not able to differentiate the two northern species from each other. Furthermore, genetic subdivision of the California species recovered in the mtDNA analysis failed to align with other lines of inference and therefore was regarded as intraspecific genetic variation. As the Coast Horned Lizard has suffered precipitous population declines across much of its range, discovering that it is comprised of three genetically isolated species elevates the importance of conserving what remains of its coastal habitat.

Communal Egg-laying More Widespread Among Herps than We Thought

Historically, communal egg-laying in reptiles and amphibians has been viewed as an uncommon phenomenon and hypotheses

to explain instances of this phenomenon often have invoked a paucity of suitable oviposition sites. The authors of this paper suggest that this paradigm is false. They performed a meta-analysis of published accounts of communal egg-laying and found the phenomenon to be far more pervasive than previously acknowledged. Failure to recognize the prevalence of communal egg-laying in these groups may stem from a general lack of knowledge of oviposition behavior (reproductive biology is known for perhaps as few as 7% of squamates of the southern continents and Asia). Furthermore, it has long been noted that herp species known to engage in communal egg-laying frequently lay solitarily as well. Through game theory, the authors illustrate scenarios that would maintain both communal and solitary egg-laying strategies in a population. This work demonstrates the scarcity of knowledge about egg-laying and the importance of understanding reproductive behavior in amphibians and reptiles.

Niche Tracking and Adaptation in *Liolaemus* Lizards

Animals seem well adapted to their environments and genetic theory suggests that quantitative traits should be able to evolve quickly to fit changing environmental conditions. However, studies of niche evolution repeatedly recover a strong signal of phylogenetic niche conservatism (stasis). To explore this paradox, the authors of this paper collected distribution, physiological (e.g., body temperature, rates of heating and cooling), and ecological (thermal environment) data for 32 species of Chilean *Liolaemus* (Iguania: Liolaemidae). Using a phylogeny of the genus, they reconstructed environmental conditions inhabited by the ancestral lineages along the phylogeny; this was subsequently analyzed for patterns of niche evolution. Physiological data and environmental conditions were also investigated for correlations. Interestingly, temperature preference and physiology seem capable of evolving rapidly to new conditions (i.e., exhibit a strong correlation); however a strong phylogenetic signal of niche conservatism was recovered from the phylogenetic analysis. Given the changes in climatic conditions during the late Cenozoic in South America and the ability of the lizards to adapt quickly, what explains the strong phylogenetic signal? The authors invoke "niche tracking," changes in distribution to follow favorable conditions, to explain this. Further, they suggest that while adaptation occurs rapidly, perhaps it only allows *Liolaemus* populations to change to a moderate degree; they are therefore unable to adapt to wide fluctuations and must overcome these types of changes via niche tracking. These findings illustrate that perhaps the ability to adapt quickly to new environmental conditions and phylogenetic niche conservatism are not necessarily contradictory.

Labra, A., J. Pienaar, and T. F. Hansen. 2009. Evolution of thermal physiology in *Liolaemus* lizards: adaptation, phylogenetic inertia, and niche tracking. The American Naturalist 174:204-220.

Patterns of Size Evolution in *Amphiuma* Salamanders

Amphiumidae is a family of aquatic, limb-reduced salamanders from the southeastern United States comprising three species: the one-, two- and three-toed amphiumas. The later two species achieve enormous size (>65 cm in total length and rivaling only members of the family Cryptobranchidae). Using genetic samples from across the range of the family, the authors conducted phylogenetic analyses of this group (both mitochondrial and nuclear DNA, analyzed separately). Interestingly, these analyses revealed that the two large species were not each other's closest relative (contrary to earlier studies); the large two-toed is most closely related to the modest-sized one-toed and more distantly related to the similarly-sized three-toed. This suggests that either the two large species underwent gigantism independently or, alternatively, the one-toed species experienced a size-reversal. Furthermore, as the one- and two-toed amphiumas are sympatric, this finding could represent an example of character displacement, whereby coexisting lineages diverge in some way to reduce interspecific competition. Alternatively, as the two species are rarely syntopic and the one-toed occupies a much smaller range than the other two species, this might represent the evolution of a small specialist from a large generalist (the authors favor this latter hypothesis). Finally, the authors posit that this reduction in body size may have been accomplished through neotony (the retention of juvenile characteristics); as evidence for this, they point to the fact that one-toed amphiuma reach sexual maturity earlier than their larger relatives.

Bonett, R. M., P. T. Chippindale, P. E. Moler, R. W. Van Devender, and D. B. Wake. 2009. Evolution of gigantism in amphiumid salamanders. PLoS ONE 4(5):e5615. doi:10.1371/journal.pone.0005615.

Hawksbill Turtles Go with the Flow When Dispersing

All species of sea turtles are recognized as either threatened or endangered. Unfortunately, efforts to conserve them are hampered, as little is known about the factors that contribute to hatchling dispersal. Traditionally, studies trying to assign samples from a mixed-stock to separate sources would perform a one-to-many assignment analysis (one stock, many sources). However, as animals from the sources are also going to other, unsampled mixed-stocks, a many-to-many mixed stock analysis is much more appropriate. Using a many-to-many method recently developed to investigate dispersal, the authors of this study analyzed genetic samples accumulated from a foraging aggregation of juvenile hawksbill turtles (*Eretmochelys*) in the Cayman Islands and from likely rookeries throughout the Caribbean Sea. Their findings demonstrate that the Cayman Islands foraging aggregation is

indeed derived from animals from every corner of the Caribbean. Furthermore, results from simulations using high-resolution ocean current data and a passive drift model of dispersal were significantly correlated with the recovered feeding aggregation genetic composition, suggesting that ocean currents play an important role in hatchling dispersal. The simulations also reveal that there is a high degree of dispersal pattern heterogeneity among the rookeries. While these results divulge how complex the system is, these findings also greatly inform sea turtle conservation efforts.

Behavior Evolution in *Anolis*

We have known for some time that adaptive radiations often lead species occupying similar microhabitats to evolve similar morphologies (the "ecomorph" paradigm). Does this phenomenon also lead species to evolve similar behaviors? To answer this question, the authors of this study investigated 13 *Anolis* species belonging to various ecomorph types at several Caribbean sites. They collected extensive behavioral and microhabitat data (including territorial display and territory size, visibility, and overlap). Analyses of these data were then performed to reveal correlations between ecomorph type and behavioral traits. Analyses performed include MANOVA (which controls for phylogenetic relationship), regression, and principal components analysis (PCA). Indeed, when the results from the PCA analysis were plotted in two dimensions, the various ecomorphs clustered together. The MANOVA analysis also recovered a strong correlation between ecomorph type and behavior. Post-hoc ANOVAs revealed that the data strongly support a correlation between ecomorph type and amount of male-male territorial overlap but not between ecomorph and display behavior. In particular, male ground-trunk specialists tolerate significantly more males with overlapping territories than male twig specialists do. Furthermore, it was revealed in the regression analyses that *Anolis* species occupying microhabitats with similar visibilities also engage in similar territorial displays. This study definitively demonstrates that like morphology, behavior is reflective of the environment in which the organism exists.

Johnson, M. A., L. J. Revell, and J. B. Losos. 2010. Behavioral convergence and adaptive radiation: effects of habitat use on territorial behavior in *Anolis* lizards. Evolution (in press). doi: 10.1111/j.1558–5646.2009.00881.x.

Sister Taxon to New World Pitvipers Revealed

Over the last decade, research into viperid systematics has revealed many new insights. For instance, we now know that New World pitvipers form a clade and likely are derived from a single dispersal across the Bering Land Bridge; however, attempts to discern which group of Asian pitvipers gave rise to them have not succeeded. To investigate this, the authors of this paper accumulated sequence data from seven genes (four mitochondrial; three nuclear) for representatives from every pitviper group. Analyses of these data revealed that New World pitvipers are sister to the genus *Gloydius*; interestingly, members of this genus were once considered congeneric with members of the New World *Agkistrodon*. Furthermore, this analysis found two enigmatic species, *Ovophis okinavensis* and *Trimeresurus gracilis*, falling outside their respective genera and instead forming a clade sister to the *Gloydius* + New World pitviper clade. The authors contend that these two species should be removed from their respective genera and placed together in a new genus (of which they are preparing a description). This study further illustrates the utility of incorporating nuclear data into studies of phylogenetic relationships, particularly in groups where mitochondrial DNA data alone has failed to resolve deeper-level relationships.

Malhotra, A., S. Creer, C. E. Pook, R. S. Thorpe. 2010. Inclusion of nuclear intron sequence data helps to identify the Asian sister group of New World pitvipers. Molecular Phylogenetics and Evolution 54(1):172–178.

Chytrid Extirpations are Non-random

When *Batrachochytrium dendrobatidis* (*Bd*) infection spreads through a region and causes local extirpations, are the extirpations random or do certain ecological characteristics make one species of frog more prone to be eliminated than another? If species with small distributions are disproportionately affected, *Bd* epizootics should have a homogenizing effect on regional diversity. Using data from eight sites across Panama and Costa Rica, the authors of this study investigated the changes in patterns of frog diversity before and after *Bd* swept through the region. The results of this study show that *Bd* epidemics disproportionately remove locally endemic species and that frog communities are more homogeneous after *Bd* passes through. Prior to *Bd*, the various localities exhibited a strong positive correlation between geographic distance and community dissimilarity; afterward, this correlation was no longer significant. Further analysis revealed that the sites had significantly more similar frog communities after the epizootic than would be expected if the extirpations were randomly distributed. Post-*Bd* homogeneity also extended to familial-diversity, reproductive mode, and microhabitat. This study demonstrates the need to be concerned about not only the local but also the regional impacts of *Bd*.

Importance of Venom in Feeding Strategies of Giant Varanids

Recent studies have found that, contrary to previous speculation, the Komodo Dragon (*Varanus komodoensis*) possesses venom and likely does not rely on bacterial infection to subdue prey. However, the degree to which the venom delivery system is developed and the complexity and potency of the venom has remained unclear. To investigate this phenomenon, the authors analyzed the cranial mechanics and venom of *V. komodoensis*. Their results confirmed previous findings that the skull of *V. komodoensis* is unable to sustain large bite forces (relative to similar large reptilian predators such as *Crocodylus*). However, previous studies underestimated potential bite force by assuming that optimal forces were achieved when the mouth was closed; computer simulations conducted in this study showed that maximal bite force occurs when the mouth is open at an angle of 20°. Instead, the skull seems best suited for stresses associated with pulling forces (similar to sharks and saber-toothed cats). Analyses of the venom found it to possess a diverse array of chemicals, including toxins known to exhibit anti-coagulant, hypotensive, hemorrhagic, and shock-inducing properties (many of these proteins have also been found in other members of the clade Toxicofera). Additionally, magnetic resonance imaging revealed large, paired mandibular venom glands (running parallel to the salivary glands), each divided into five compartments and possessing ducts that deliver venom into the spaces between the teeth. These venom glands combined with strong pulling forces and large, serrated teeth provide *V. komodoensis* with a highly effective venom delivery system. As previous studies have shown that squamate lineages that adopt feeding strategies not reliant on venom (e.g., constricting, egg-eating) quickly lose their venom capabilities (as venoms and their accompanying architecture are metabolically expensive), the fact that *V. komodoensis* still possesses a highly-derived, functioning venom apparatus strongly suggests that it remains an essential part of their feeding strategy. Furthermore, as the skeletal morphology of the extinct *Varanus priscus* closely parallels that of *V. komodoensis*, this implies that *V. priscus* also likely utilized venom in its feeding strategy and therefore was the largest venomous animal to have walked the face of the earth.

Fry, B. G., and Colleagues. 2009. A central role for venom in predation by *Varanus komodoensis* (komodo dragon) and the extinct giant *Varanus* (*Megalania*) *priscus*. Proceedings of the National Academy of Sciences 106:8969–8974.

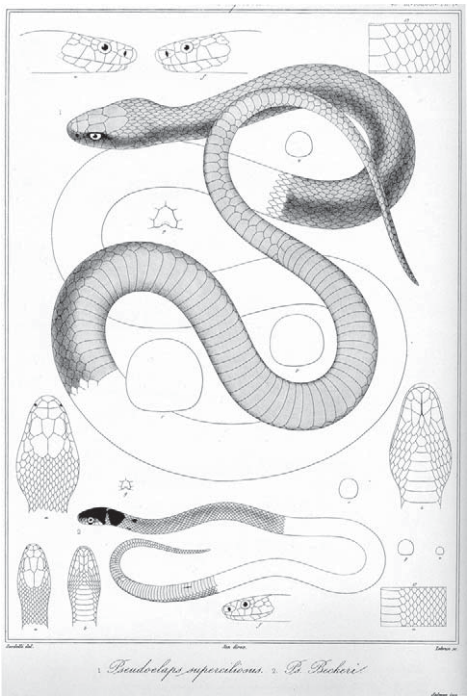
No passion in the world is equal to the passion to alter someone else's draft.
—H. G. Wells

Autobiographies and Biographies



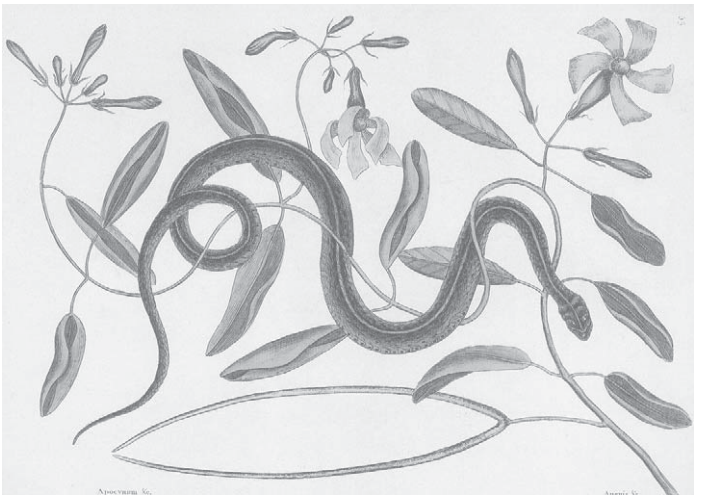
When I was young, one of my favorite pastimes was to read the books of Raymond L. Ditmars, William Beebe, Thomas Barbour, Arthur Loveridge, Alexander Ruthven, and Ivan T. Sanderson and imagine the thrill of traveling to faraway places to search for amphibians, reptiles, and other exotic creatures. As I got older, looked at newer books, and actually had an opportunity to see some of the places mentioned, the pleasure intensified as I compared those experiences between the writers and my own. And if the opportunity to visit these locales did not materialize, then there was always the fallback of visualizing myself in these settings. Listed in Appendix I are some of my favorite titles.

Three new herpetological autobiographies have appeared on the scene. D. Bruce Means has written a lovely book called *Stalking the Plumed Serpent and Other Adventures in Herpetology* (2008, Pineapple Press, Sarasota, Florida; ISBN: 978-1-56164-433-9). Twenty-two vignettes document his travels over 40 years studying amphibians and reptiles, ranging from his experiences with Eastern Diamondback Rattlesnakes to Bushmasters in Costa Rica. How many herpetologists can say that they encountered five of the deadliest Australian terrestrial elapids in the field: Inland Taipan (*Oxyuranus microlepidota*), Coastal Taipan (*O. scutellatus*), Eastern Brown Snake (*Pseudonaja textilis*), Mt. Chappell Island Ti-

D. Bruce Means found that White's Treefrog (*Litoria caerulea*) preys upon the Little-Bent-Winged Bat (*Miniopterus australis*) in a cave in Queensland, Australia. Illustration from John White's *Journal of a voyage to New South Wales, with sixty-five plates of nondescript animals, birds, lizards, serpents, curious cones of trees and other natural productions.*
Imprint: London: Printed for J. Debrett, 1790.

ger Snake (*Notechis ater serventyi*), and King Brown Snake (*Pseudechis australis*). One of his most interesting observations, accompanied by an arresting photograph, was that in addition to a number of snakes preying upon the Little-Bent-Winged Bat (*Miniopterus australis*) in a cave in Queensland, White's Treefrog (*Litoria caerulea*) also preys upon the mammals. Means tells many other stories relating his field experiences with the Moccasin, Alligator Snapping Turtle, Apalachicola Kingsnake named in his honor (*Lampropeltis getula meansi*), Eastern Indigo Snake, Alabama Red Hills Salamander, Yucatán Peninsula Rattlesnake, American Alligators, and a number of species from Madagascar. This is a book well worth reading.

D. Bruce Means encountered five of the most dangerous Australian elapids in the field, including the Eastern Brown Snake (*Pseudoelaps beckeri*, now *Pseudonaja textilis*). Illustration from *Iconographie générale des ophidiens / par M. le professor Jan . . .[en collaboration avec Mr. F. Sordelli.] ...*



Imprint: Milan: chez l'auteur, [etc., etc.], 1860–1881.

The second autobiography was written by Leslie Anthony and called *Snakebit. Confessions of a Herpetologist* (2008; GreyStone Books; Vancouver, Toronto, Berkeley; ISBN 978-1-55365-236-6). Anthony was trained as a biologist (his herpetological name is Leslie A. Lowcock), working with Robert W. Murphy at the Royal Ontario Museum (ROM) for his doctorate and as a postdoc at McGill University's Redpath Museum in Canada. One of the strongest features of this book is his ability to explain complex biological principles in simple terms so the layman can understand. One example is his clear description of salamander reproductive isolation in Chapter 3 called "A Salamander under a Log."

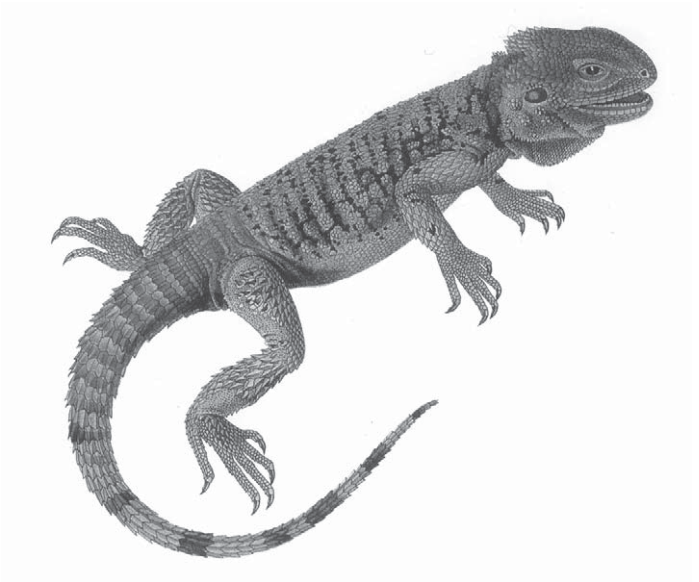
Upon emergence from hibernation in Manitoba, Canada, hundreds of Red-Sided Gartersnakes (*Thamnophis sirtalis parietalis*) form snake balls where scores of males pursue and envelop a female in order to mate. Females secrete a sexually attractive pheromone which attracts potential mates. These spectacular aggregations are described by Anthony in the chapter "Ode to a Gartersnake"—"A human version of this chemical would be worth billions, its power evident in the almost comical spectacle of "mating balls" observed at dens in the spring, where a single pheromone-secreting female is assailed by up to a hundred males. On second thought, writhing masses of humans would not only look ridiculous but also pose a definite traffic hazard."

He captures our keen fashion sense—"It was déjá vu all over again when I realized [groups of herpetologists] were also executing familiar fashion-suicide pacts. Herpetologists thought cargo pants, with all their loops and sagging pockets, were invented for them, and they'd long taken ownership with gusto. But their almost comical devotion to khaki was more CRAP than GAP; the official uniform of established herpetologists was cargo shorts, Hawaiian shirt, white tube socks, and running shoes that had never been run in."

At the summer herp meetings at University of Michigan in 1988, the debut of the delightful rock opera ROMMY occurred, watched by ca. 3000 delegates and me. This clever satiric creation, based on conflicting theories of phylogenetics and phenetics, was the brainchild of the ROM group and other Canadian herpetologists who created the characters, wrote the score, and played a variety of instruments for the performance—"Somehow we pulled it off, helped by vast amounts of beer consumed during the performance, and a boozed-to-the-hilt crowd that clapped, laughed, and guffawed from the opening bar."

The Common Garter Snake (*Thamnophis sirtalis sirtalis*) includes 12 recognized subspecies, one of which ranges into Manitoba, Canada. The Red-Sided Garter Snake (*T. s. parietalis*) occurs in prodigious numbers and when emerging from den sites in the Spring as described by Leslie Anthony, is one of the most overwhelming snake assemblages in the world.

Illustration from Mark Catesby's *The natural history of Carolina, Florida and the Bahama islands: containing the figures of birds, beasts, fishes, serpents, insects, and plants: particularly the forest-trees, shrubs, and other plants, not hitherto described, or very incorrectly figured by authors. Together with their descriptions in English and French. To which, are added observations on the air, soil, and waters: with remarks upon agriculture, grain, pulse, roots, &c. To the whole, is prefixed a new and correct map of the countries treated of.*



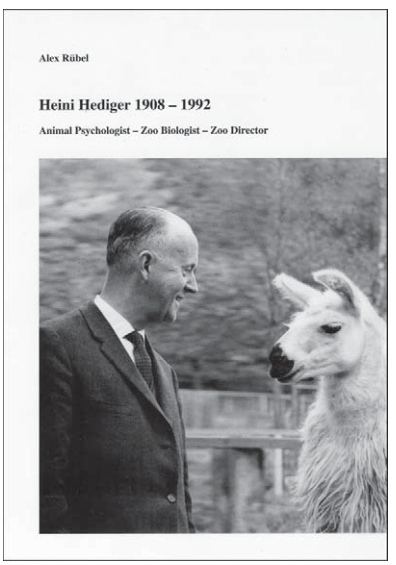
Catesby calls this "*Anguis viridis maculatus*. The green spotted snake." (vol. 2, pl. 53). His description says: "These Serpents sometimes grow to four times the Bigness of the Figure, are said not to be venomous, and are great Robbers of Hen-Roosts, sucking Eggs, tho' their Size seldom enables them to devour the Fowls.

As the change of Marks and Colour in some Serpents cause Confusion in distinguishing them, I would willingly avoid Mistakes, by describing the same Snake twice, and multiplying the Kinds to more than there are: And I am diffident in determinating, whether this be a different Kind from the spotted Ribbon Snake, p. 51. Which somewhat resembles it, tho' of a different Colour."

In the Beehive Press facsimile of selected plates (1974), Joseph Ewan identifies it as *Thamnophis ordinatus* [Linn.] and adds that the plate is cited in L. M. Klauber's discussion of the snake in Copeia 1948, (1):8–10. Today, this taxon is known as the Common Garter Snake (*Thamnophis s. sirtalis*). Credit: Courtesy of Smithsonian Institution Libraries, Washington, DC.

Anthony describes many experiences with a variety of herps from Tortuga Island Rattlesnakes to Armenian Vipers. One of the most interesting was his encounter with the Bola or Fiji Cobra (*Ogmodon vitianus*), a small, exceedingly rare elapid from the Fiji Islands. His writing style is terrific and his oblique sense of humor permeates the book—I laughed aloud many times. I know some of the herpetologists he mentioned and his descriptions of their eccentricities is spot on. Do pick up a copy.

The next book is entitled *LIZARD MAN. The Life and Adventures of Bert Langerwerf*, by Bert Langerwerf and Russ Gurley (2009, Living Art Publishing, Ada, Oklahoma; www.livingartpublishing.com; ISBN 0-9787556-6-9). The late Bert Langerwerf was an extraordinary reptile breeder, reproducing over 135 species. He was the owner of Agama International, Inc., a seven-acre breeding facility in Alabama where thousands of lizards were produced annually. He personally constructed over



Bert Langerwerf published an account of captive management and reproduction of the Roughtail Rock Iguana (*Agama stellio*, now *Laudakia stellio*) in 1994. Illustration from Georges-Louis Duvernoy, *La Règne Animal par Georges Cuvier, Reptiles volume. Disciple edition*. Paris 1842.

400 outdoor terraria and outbuildings by hand. This book is large: 467 pages, hundreds of photographs, a list of his many papers on captive management, and reasonably priced. For anyone interested in the history of herpetoculture, these photos alone are worth the price of the book as many prominent reptile and amphibian breeders are pictured. His remarkable life is detailed in an obituary published in *Herpetological Review* (2008, 39:400–401).

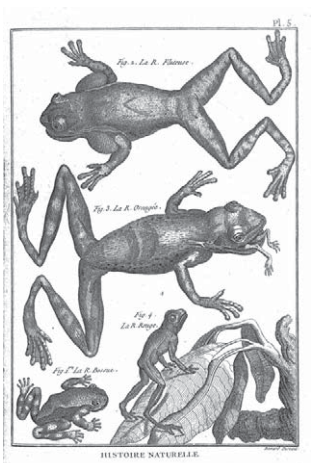
An excellent biography has also been recently published. Heini Hediger, late Director of the Basel and Zürich Zoos in Switzerland, wrote several seminal books on psychology, psychopathology, and captive management which have influenced zoo biologists. He also published a number of papers in herpetology and his doctoral dissertation "Beiträge zur Herpetologie und Zoogeographie Neu Britanniens und einiger umliegender Gebiete (Contribution to the herpetology and zoogeography of New Britain and some adjacent regions)" included information on the habits of species collected there and the relationship to the environment. The venomous snake *Parapistocalamus hedigeri* was named in his honor by Jean Roux in 1934. Hediger described three taxa: Amiralty Island Webbed Frog (*Discodeles vogti* [Hediger 1934]), Roux's Skink (*Lipinia rouxi* [Hediger 1934]), and a worm snake (*Typhlops buehleri* Hediger 1933, now *Ramphotyphlops depressus*).

Alex Rübel has published a biography detailing his life and extraordinary contributions to zoo biology. The book is called *Heini Hediger 1908–1992. Animal Psychologist — Zoo Biologist —Zoo Director* (English edition 2009, Sales point: Bookstore Beer AG, St. Peterhofstadt 10, 8022 Zurich, Switzerland; ISBN 978-3-906262-22-2).

Cover of book on life of Heini Hediger.

During the period between 1932 and 1943, Hediger published many papers in herpetology on a variety of topics (Appendix II; Honegger 2009).

Amphibian Decline and Extinction

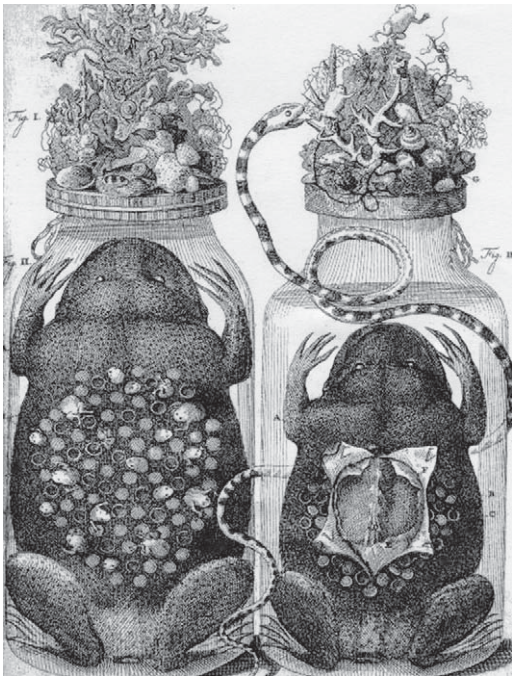


We began this project to summarize our understanding of why amphibian populations declined, some to extinction, late in the 20th and early in the 21st century. We know enough now to place this problem in a larger context of historical and present-day biodiversity losses. The knowledge we have raises several final questions: How will humans react to an increased awareness that Earth's biodiversity is diminishing? What are these losses telling us about our place on the planet, our role in the biosphere? What is our role in conserving biodiversity as we become custodians of a planet that has clear limitations? And how can we pass on to future generations the wisdom needed to make sound environmental decisions? The answers to these questions will tell us much about ourselves, and science will take us only part of the way along that journey.

One mystery yields another.

—James P. Collins and Martha L. Crump

When a zoo visitor hears about the global decline and possible extinction of amphibians, they may ask what non-technical books are available to learn more about the subject. In the past, I have recommended several: *In Search of the Golden Frog* by Marty Crump, *Tracking the Vanishing Frogs: An Ecological Mystery* by Kathryn Phillips, and *A Plague of Frogs: The Horrifying True Story* by William Souder. James P. Collins and Martha L. Crump have added another book to the list which is readable and comprehensible for the layman but is also valuable for the specialist. To achieve this balance, the authors have included hundreds of endnotes to document sources as well as explain situations and concepts in greater detail. Their book is called *Extinction in Our Times. Global Amphibian Decline* (2009, Oxford University Press; ISBN 978-0-19-531694-0). There are many reasons for every zoo herpetologist to own this book. First, the text paints an historical picture of the problem, from the beginning days of skepticism that declines were a real phenomenon to the present day when humans are trying to deal with the potential extinction of an entire class of vertebrates. Second, the role of infectious diseases, climate change, and other deleterious factors are explained in detail. Third, the authors present a primer as to how science policy, future research, and other initiatives should be conducted to address the problem. Finally, they address the role of zoos: "Although they are committed to conservation, for understandable reasons many zoos cannot allocate substantial space or personnel to species with little potential for exhibits. Nevertheless, collection-based institutions are the only ones maintaining species on a continuing basis to ensure their survival, because few governmental agencies have made such commitments. Policies are needed to guide the housing and management of large numbers of threatened or endangered, perhaps non-charismatic, species (p. 180)."



Every zoo professional must become

James P. Collins and Martha L Crump have written a rigorous but sobering overview of global amphibian declines. Illustration from *Tableau encyclopédique et méthodique des trois règnes de la nature ... Erpétologie. / Par m. l'abbé Bonnaterre ...*

Imprint: Paris: Chez Panckoucke, 1789. Credit: Library of Roy McDiarmid.

familiar with and conversant about the scope of the problem outlined by the authors in order to facilitate change in zoos and aquariums by convincing administrators and policy makers that greater human and financial resources must be allocated to attack this extraordinary crisis. In fact, it would be a great idea to buy a few extra copies and circulate them among your bosses!

Collins and Crump present mounting evidence in their book that humans are witnessing an amphibian extinction event. Could it be that the only way that frogs will be seen in the future is like this? Illustration from Frederik Ruysch's book on a natural history cabinet in 1710—*Frederici Ruischii ... Thesaurus animalium primus = / Het eerste cabinet der dieren / van Frederick Ruysch ...*

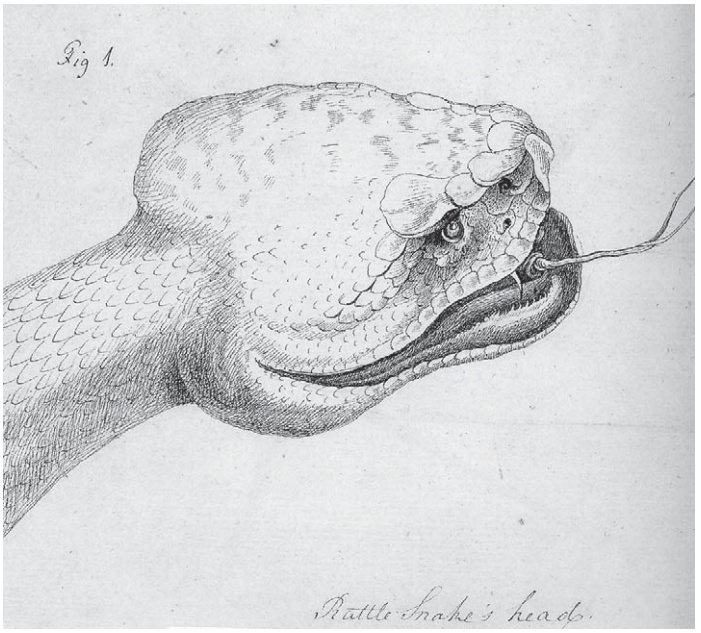
This recent paper is required reading for all zoo and aquarium personnel: Voyles, J., et al. 2009. Pathogenesis of chytridiomycosis, a cause of catastrophic amphibian declines. Science 326:582–585.

Snakes: Ecology and Conservation



When people abroad see a live snake they rush upon it and batter it to death with sticks and stones, as though every inch of it possessed a separate and fifty-feline power of life calling for special destruction; then they pick up what is left of it, and after an uncertain interval of time, very often in the broiling midday heat of the tropics, put it into a bottle of cachasse, canha, aguadiente, or some other coarse spirit which disintegrates its actual structure, label it with the wrong name, and send it home.

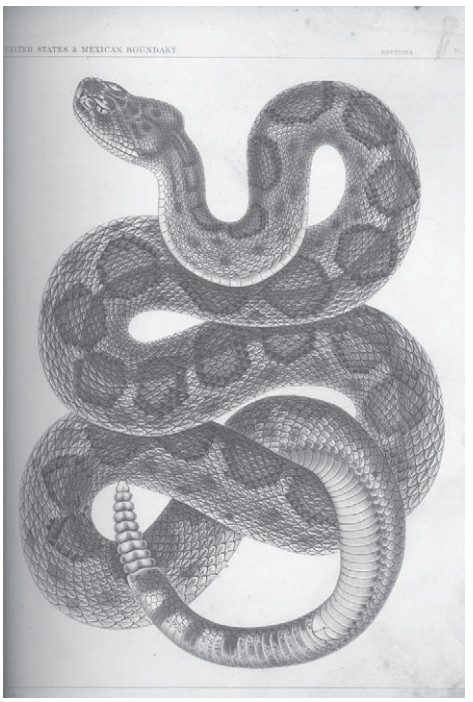
—Arthur Stradling, On the treatment of snakes in captivity, 1882

A new book on snakes provides the most current information on ecology and conservation. Illustration from *Naturgeschichte des Thierreichs ... vol. 3.* by Gotthilf Heinrich von Schubert in 1869.
Imprint: Esslingen, J.F. Schreiber. Credit: Courtesy of Polly Lasker, Smithsonian National Zoological Park Library Collection.

In 1987, the book *Snakes—Ecology and Evolutionary Biology* was published and was followed six years later by the next in the series *Snakes: Ecology and Behavior*. The third one has now appeared: *Snakes: Ecology and Conservation*, edited by Stephen J. Mullin and Richard A. Seigel (2009; Comstock Publishing Associates, A Division of Cornell University Press, Ithaca and London; ISBN 978-0-8014-4565-1). Eleven chapters are geared to conservation and present the most current information on molecular phylogeography; population and conservation genetics; distribution and habitat; behavioral ecology; reproductive biology, population viability, and options for field management; captive rearing, translocation, and repatriation; habitat manipulation; and ecosystem properties. [Full disclosure: I contributed to the chapter on combating ophiophobia.].

In 1792, William Bartram describes an encounter with the Timber Rattlesnake (*Crotalus horridus*) in the Catskill Mountains, located in the state of New York, in his book *Travels through North and South Carolina, Georgia, East and West Florida, the Cherokee country, the extensive territories of the Muscogulges, or Creek confederacy, and the country of the Chactaws; containing an account of the soil and natural productions of those regions; together with observations on the manners of the Indian*—". . . when at the instant, my father being near, cried out 'A rattle snake, my son!' and jerked me back, which probably saved my life. I had never seen one before. That was of the kind which our guide called a yellow one, it was very beautiful, speckled and clouded." (p. 224). According to librarian and author Judith Magee, this unpublished illustration by Bartram is in the collection of the Natural History Museum in London. It was drawn during his travels in the south. The page measures 150 × 160 mm, but this has been trimmed by someone in the Museum in the past. Figure 2 is the head of a Cottonmouth or Water Moccasin (*Agkistrodon piscivorus*) and she suspects they were drawn together on the same sheet of paper but have subsequently been cut up for mounting. There is no text with these drawings but they were sent to his patron John Fothergill in 1774. Credit: By permission of the Trustees of the Natural History Museum, London.

Rattlesnakes



But let us again resume the subject of the rattle snake; a wonderful creature, when we consider his form, nature, and disposition. It is certain that he is capable by a puncture or scratch of one of his fangs, not only to kill the largest animal in

America, and that in a few minutes time, but to turn the whole body into corruption; but such is the nature of this dreadful reptile, that he cannot run or creep faster than a man or child can walk, and he is never known to strike until he is first assaulted or fears himself in danger, and even then always gives the earliest warning by the rattles at the extremity of the tail.

—William Bartram in *Travels…*in 1791

Rattlesnakes being such popular zoo exhibits, there are several books which are essential for the zoo herpetologist's reference library—*The Rattlesnakes, Genera Sistrurus and Crotalus. A Study in Zoogeography and Evolution* by Howard K. Gloyd, 1940; *Rattlesnakes: Their Habits, Life Histories, and Influence on Mankind* by Laurence M. Klauber, 1956; *The Venomous Reptiles of Latin America* by Jonathan A. Campbell and William W. Lamar, 1989; *Biology of the Pitvipers* by editors Jonathan A. Campbell and Edmund D. Brodie, Jr., 1998; *Rattlesnake: Portrait of a Predator* by Manny Rubio, 1998; and *The Venomous Reptiles of the Western Hemisphere* by Jonathan A. Campbell, William W. Lamar, with contributions by Edmund D. Brodie III ... [et al.], 2004.

A new book entitled *The Biology of Rattlesnakes* (2008, Loma Linda University Press, Loma Linda CA; over 600 pages, 50 chapters, and over 90 color images; edited by William K. Hayes, Kent R. Beaman, Michael D. Cardwell, Sean P. Bush, foreword by Gordon W. Schuett; ISBN 978-1594190-011-6), presents the most up-to-date research by nearly one hundred authors specializing in rattlesnake biology. It is not necessary to go into specifics here in terms of content; suffice it to say that virtually every aspect pertaining to the life of a rattler is covered in detail. This is an awesome book, in part because so much original material is included by these researchers. I cannot remember a single book in herpetology with a larger number (>50) of original contributions. The book is divided into Research and History, Systematics, Morphology and Physical Ecology, Learning and Evolution of Behavior, Behavioral Ecology of Feeding and Defense, Population Ecology and Habitat Use, Thermal Ecology, Spatial Ecology, Reproductive Behavior and Ecology, Conservation Ecology and Education, Venom, and Snakebite. Of particular interest to the zoo worker will be the chapter on San Diego Zoo (SDZ) curator and rattlesnake authority Laurence M. Klauber by his granddaughter Janet. Another chapter describes the many observations contained in his monumental two-volume book which were made with Clarence B. (Si) Perkins and later Charles E. Shaw at the SDZ (see Murphy, 2007 for biographies).

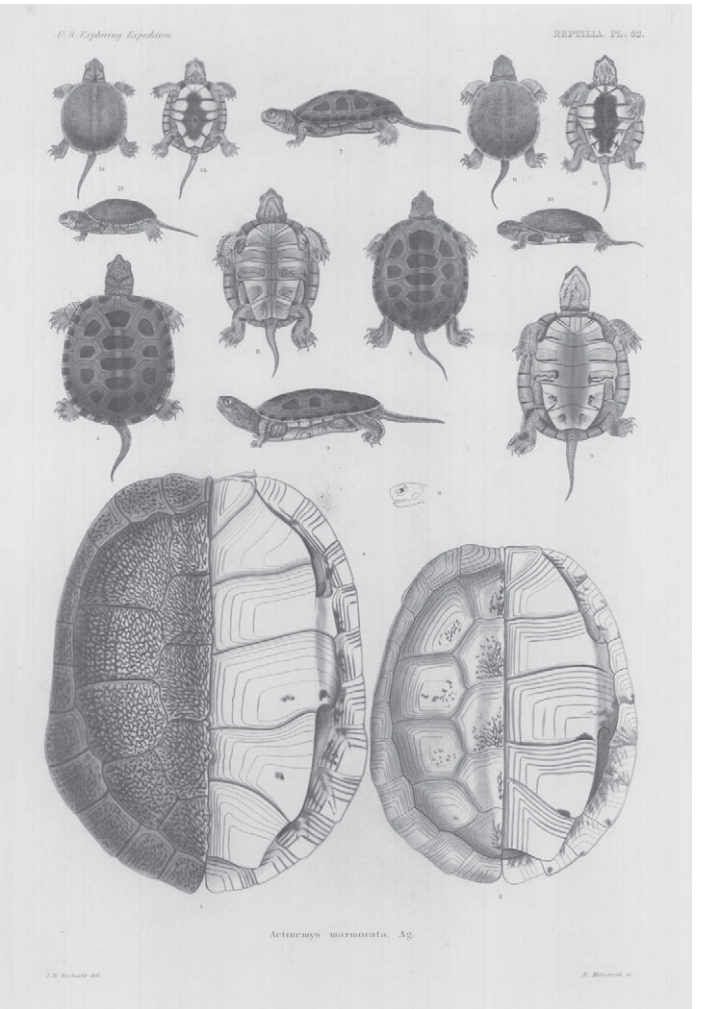
In the southwestern United States, the attendees at annual rattlesnake roundups destroy thousands of Western Diamondback Rattlesnakes (*Crotalus atrox*). Many herpetologists have never attended one of these events; if they did so, they would be horrified by the barbaric and inhumane treatment accorded the snakes by so-called civilized human beings. Years ago, I watched a young girl, wearing a party dress covered in blood, chop the heads off restrained living snakes with a meat cleaver. What is remarkable and unsettling is that these displays showing the most negative side of human behavior still exist, attract thousands of onlookers, and animal rights groups ignore the carnage. Illustration from *Reptiles of the Boundary ... With Notes by the Naturalists of the Survey* by Spencer F. Baird, 1859.

I was pleased to see the names of many zoo people as authors: Allison Alberts, Fred Antonio, Tracey Brown, Nick Clark, Craig Ivanyi, Jeffrey Lemm, Hugh McCrystal, Jean-Pierre Montagne, R. Andrew Odum, Douglas Whiteside, as well as those from the academic community who have collaborated with them on various projects.

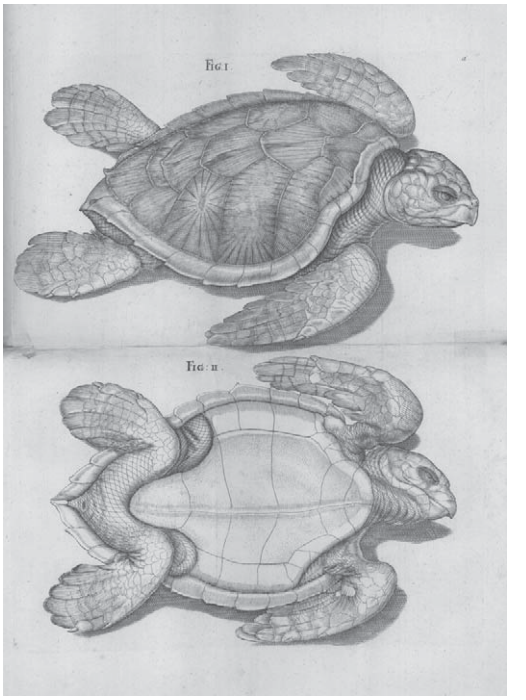
Turtles, Tortoises, and Terrapins of the United States and Canada

Everyone recognizes a turtle, of whatever size, shape, color, or origin. Would that the names applied to them were so straightforward—"turtle," "tortoise," "terrapin"—they mean one thing to one person, something else to another. Biologically all members of the order Testudines are correctly called turtles. Terrapins and tortoises are certainly turtles; tortoise is usually applied to terrestrial turtles, particularly the larger ones; terrapin is usually applied to edible, more or less aquatic hardshelled turtles.

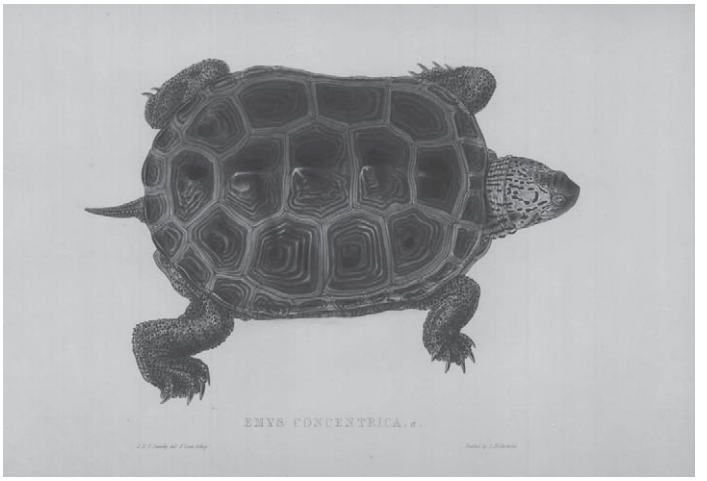
—Carl H. Ernst, Jeffrey E. Lovich, and Roger W. Barbour, in *Turtles of the United States and Canada* in 1994



In 1972, Carl H. Ernst and the late Roger W. Barbour published *Turtles of the United States*. Twenty-two years later, an expanded *Turtles of the United States and Canada* appeared by Ernst, Jeffrey E. Lovich, and Barbour. Now, the second edition of *Turtles of the United States and Canada* by Ernst and Lovich has been written and this tome is enormous (2009; Johns Hopkins University Press, Baltimore, Maryland; xii, 827 pp.: ill. (chiefly col.), maps, ISBN 13:978-0-8018-9121-2; 10: 0-8018-9121-3), only approximately 100 pages less than the combined number of pages (which were smaller in size) of the earlier books. Do not be fooled into believing that if you own the first two books, purchasing this second edition is unnecessary—this latest version is dramatically different. Although the sub-categories are essentially the same in each species account (i. e., recognition, karyotype, fossil history, distribution, geographic variation and so on) for all books, the new one is published in a larger format, contains more information, and a greater number of excellent color plates accompany the accounts. Taxonomic name changes after the 1994 edition are included.



There is in this second edition an extensive section on conservation, a topic missing in the earlier books. This addition reflects the increasingly perilous plight of chelonians globally. W. B. Spencer in *The Victorian Naturalist* in 1921 explains the situation applicable to aquatic turtles "... fresh-water fauna is disappearing rapidly, and unless we now make an organized effort it will be too late to study it effectually, and future generations will wonder what manner of people we were not to leave behind us some adequate record of the marvellously interesting forms of animal life which we had succeeded in exterminating . . . "

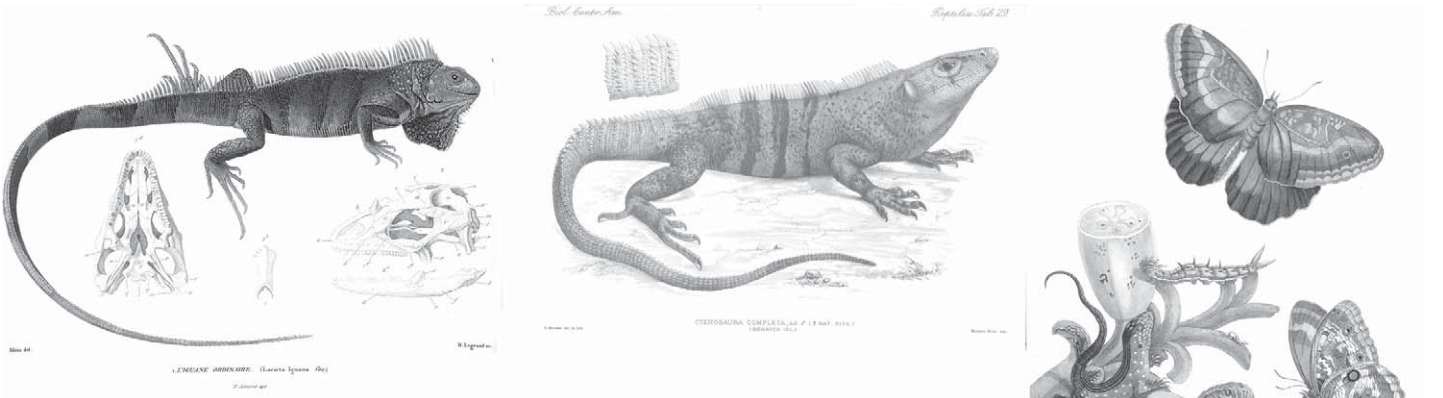


In the August 2009 issue of *Turtle Survival Alliance Newsletter*, an article by Heather Lowe shows current turtle legislation as it relates to commercial harvest in the eastern United States (pp. 49–52). For membership information, visit www.TurtleSurvival.org and also read the article by Dwight Lawson (2004. Partners in saving turtles: The Turtle Survival Alliance. Herpetol. Rev. 35:110).

Lizards and Crocodilians of Southeastern United States

In an earlier issue of *Herpetological Review* (2008, 39:405), I reviewed four books on the amphibians and reptiles of the southeastern United States and enthusiastically recommended all of them for the zoo biologist's library. A new one covering the lizards and crocodilians has been written: *Lizards & Crocodilians of the Southeast* by Whit Gibbons, Judy Greene, and Tony Mills (2009; The University of Georgia Press, Athens, Georgia; ISBN 978-0-8203-3158-4). This book equals the quality of the earlier ones and should be purchased in haste to complete the set.

Many of the chelonians pictured in the revised book by Carl Ernst and Jeffrey Lovich are under siege. Clockwise, from lower left are plate XXXIII– Diamondback Terrapin (*Emys concentrica*, now *Malaclemys terrapin*) from *Tortoises, Terrapins, and Turtles Drawn from Life* by James de Carle Sowerby and Edward Lear, 1872; plate 32 –Pacific Pond Turtle (*Emys marmorata*, now *Actinemys* [=*Clemmys*] *marmorata*) from *United States Exploring Expedition, Baird/Girard Herpetology*; early drawing of a sea turtle from *Physikalish- anatomische Bemerkungen über die Schildkröten, aus dem Lateinischen übersezt. Mit 10 Kupfertafelen* by Christoph Gottwald, 1781. All sea turtles are now endangered, mostly due to human causes. Credit: From the collections of the Ernst Mayr Library, Museum of Comparative Zoology, Harvard University.



How to Exhibit an Anole

Some of the Anoles make very charming pets. Personally, I think them to be the most beautiful of all Lizards. Those I have fortunate enough to possess have proved themselves hardy while in confinement. They are extraordinarily active, and, for Reptiles, very intelligent: they soon become tame enough to take a fly from the fingers. Owing to their great activity and power of changing colour, mine have several times escaped from their case.

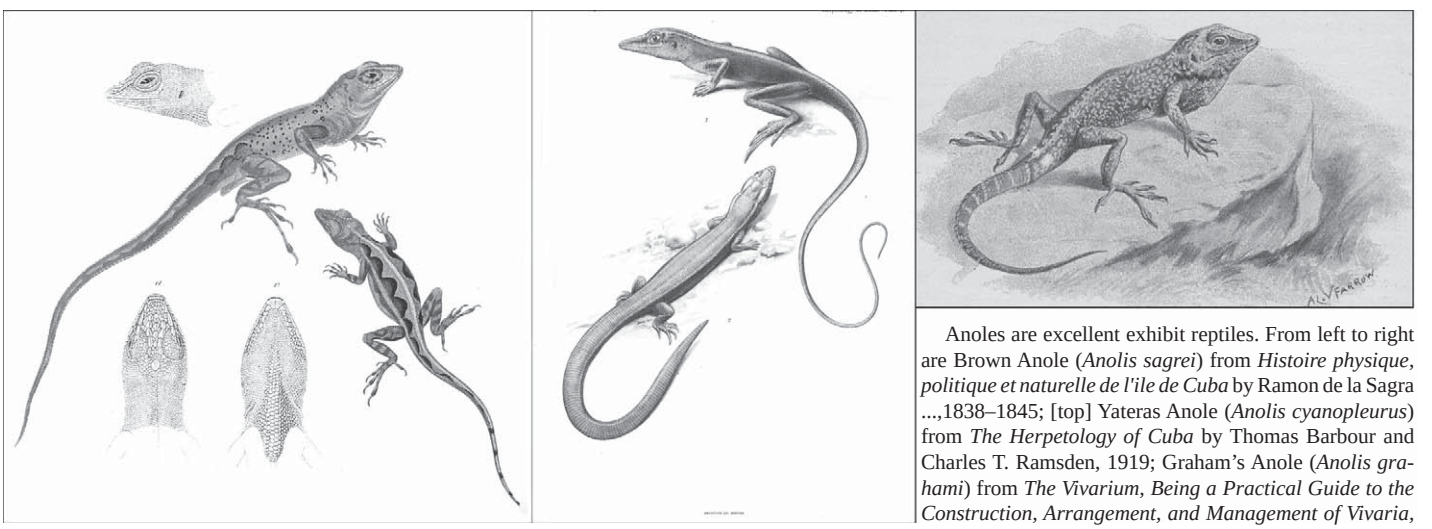
—Reverend Gregory C. Bateman, *The Vivarium*, 1897

During the mid-1950s, I regularly visited the reptile building at the Lincoln Park Zoo in Chicago. In the middle of the public area was a large free-standing planted terrarium housing dozens of American and Brown Anoles. Throngs of visitors always surrounded this enclosure. The anoline life style was on display—male-male combat with dewlap extension, color change, sexual selection, courtship and copulation, oviposition, hatching, and feeding. Even in this limited space, male Brown Anoles were dominating male American Anoles. It was clearly the most popular exhibit in the building, due in large part to the fact that the lizards were very active, attractive, and familiar.

An anole exhibit is the perfect way to introduce the zoo patron to evolutionary biology, and the task of preparing graphics and other educational elements is now much easier with the recent appearance of a superb reference—*Lizards in an Evolutionary Tree. Ecology and Adaptive Radiation of Anoles* by Jonathan B. Losos (2009; The University

In the southeastern part of the United States, invasive lizard species outnumber native forms by a two-to-one margin. From left to right are three prominent aliens pictured in early publications: Green Iguana (*Iguana iguana*) from Georges-Louis Duvernoy's *La Règne Animal par Georges Cuvier, Reptiles volume. Disciple edition* in 1842; Black Spiny-Tailed Iguana (*Ctenosaura similis*) from *Biologia Centrali-Americana. [7], Reptilia and Batrachia* by Albert C. L. G. Günther in 1885–1902; Spotted Racerunner (*Cnemidophorus lemniscatus*) from Maria Sibylla Merian's *Dissertatio de generatione et metamorphosibus insectorum surinamensium* in 1726.

of California Press, Berkeley, Los Angeles, London; ISBN 978-0-520-25591-3). The book is arranged in 17 chapters and includes the following topics: phylogenetics, evolutionary inference, anole relationships, biogeography, life history, ecology, natural selection and microevolution, form, function, and adaptive radiation, ecomorphs, and so on. Creative informative graphics and interactive displays could be developed using any one of these topics and this book is a critical source of information should one embark on a project of this kind. Anoline lizards, numbering about 380 species, can be effectively used to demonstrate the development of ecological theory, ecological questions of interest, conservation issues, and evolutionary diversification.



An Essential Reference Book

Editors often complain that bibliographies are the most error-filled part of submitted manuscripts. The reason for this may be that authors are so relieved to have finished their paper that adding the bibliography and checking the accuracy of the citations is almost an afterthought. In a thought-provoking paper by Liner and Hutchison (1998), the senior author reviewed 1000 entries and discovered that 20% were in error. Liner and Hutchison describe the proper way that citations should be listed by addressing the following elements—surname, given name, year, title, source, and ethics and professionalism. They conclude: "Although the errors of existing bibliographies are now history, we hope that this summation of some common problems will lead to increased vigilance on the part of authors, reviewers, and editors, and the incidence of errors will decline."

This goal is now much easier for an extraordinary new book published by SSAR is now available—*Biology of the Reptilia, Comprehensive Literature of the Reptilia*, Volume 22, edited by Carl Gans and Kraig Adler, compiled by Ernest A. Liner; 1,400 pages. To order this volume, please visit: http://www.ssarbooks.com.

The *Biology of the Reptilia* series (21 volumes) is an essential tool for zoo biologists (see HR 2009, vol. 40:17 for details), editors, reviewers, librarians, and others dealing with reptile biology and literature. Over 22,000 references are listed in this new book, compiled from the earlier volumes. There are several important and invaluable features—subject/species and author indices, and cross-reference index to the entire 21-volume series.

Errors can occur by copying citations from previous publications or downloading them from the internet; in both cases, these documents are sometimes erroneously cited and mistakes are perpetuated. The permanence of a printed book with "accurate" citations is essential to meet the challenge of Liner and Hutchison. This tome will be the standard for decades to come; it is unlikely that another book like this will ever again be published.

Anoles are excellent exhibit reptiles. From left to right are Brown Anole (*Anolis sagrei*) from *Histoire physique, politique et naturelle de l'ile de Cuba* by Ramon de la Sagra ...,1838–1845; [top] Yateras Anole (*Anolis cyanopleurus*) from *The Herpetology of Cuba* by Thomas Barbour and Charles T. Ramsden, 1919; Graham's Anole (*Anolis grahami*) from *The Vivarium, Being a Practical Guide to the Construction, Arrangement, and Management of Vivaria, Containing Full Information as to all Reptiles Suitable as Pets, How and Where to Obtain Them, and How to Keep Them in Health* by the Rev. Gregory C. Bateman, 1897.

Acknowledgments.—I am grateful to Emily Becker, Dana Fisher, and James Hanken from the Museum of Comparative Zoology, Harvard University, Judith Magee from the Natural History Museum in London, Kraig Adler, and Roy McDiarmid for providing some of the illustrations. Polly Lasker, Leslie Overstreet, and Daria Wingreen from Smithsonian Institution Libraries searched archival materials to locate biographical information on Catesby. David Cundall and René Honegger kindly sent literature. Judith Block reviewed early drafts and made helpful suggestions for improvement.

Murphy, J. B. 2007. Herpetological History of the Zoo and Aquarium World. Krieger Publishing Co., Malabar, Florida.

Judith A. Block is the retired registrar from the Smithsonian National Zoological Park in Washington DC. She is a founding (and now honorary) member of the Zoo Registrars' Association (ZRA), an organization in existence for over 25 years. In 2007, the organization established the "Judith Block Professional Excellence Award," a prestigious honor given to select members to recognize significant achievement in this profession; Block was the first recipient. In the following article, she reviews the book by John E. Simmons (*Things Great and Small. Collection Management Philosophies*) from the perspective of a zoo registrar.

Simmons is well known to herpetologists for he was the collections manager for many years at the University of Kansas before retirement. He is the author of two editions of *Herpetological Collecting and Collections Management*, published by SSAR in 1987 and 2002.

Essential Reading for Zoo Registrars and Others with Collections Responsibilities

JUDITH A. BLOCK
3100 Connecticut Ave., NW, Washington DC 2008, USA
e-mail: jbmurphy2@juno.com

Things Great and Small: Collections Management Policies, by John E. Simmons (2007; 208 pp.; American Association of Museums; ISBN-13:978-1-033256-03-9; ISBN-10:1-9233253-03-7) is a textbook on collections management policies and it is anything but dry. The book is totally engaging; I found myself making notes, jotting down questions and reflecting on how I would apply what I was reading. The author has a fluid style and a sense of perspective that includes humor, making the sections unexpectedly readable. I even laughed out loud a couple of times.

This frontispiece pictured is the Copenhagen natural history museum or cabinet of curiosities of Oleus Worm in 1655 with snake skins, turtle carapaces and skulls, crocodiles, and lizards hanging on the wall. These private cabinets held biological treasures, arranged in no particular order, to excite wonder. The cover of the Simmons book shows a recreation of the Worm cabinet by Rosamund Purcell for "Two Rooms," Santa Monica Museum of Art, 2003.
Worm, Oleus. 1655. *Museum Wormianum; seu, Historia rerum rariorum, tam naturalium, quam artificialium, tam domesticarum, quam exoticarum, quae Hafniae Danorum in a aedibus authoris servantur. / Adornata ab Olao Worm ...*
Imprint: Lugduni Batavorum, ex officina Elseviriorum, 1655.
Credit: From the collections of the Ernst Mayr Library, Museum of Comparative Zoology, Harvard University.

This book makes clear what collections management policies are and why they are essential. "Collections management is everything that is done to take care of collections, develop the collections and make the collections available for use." (p. 2) Policies are developed to address aspects of management and other collections-related activities and they clarify who is responsible for each; they are the basis for procedures and collection plans. Each institution has its own requirements and constraints but there are commonalities and this book is a most useful guide for developing comprehensive documents or reviewing existing policies.

Each chapter covers a particular topic, such as authority, acquisitions, dispositions, loans, documentation, access and use, ethics and appraisals. There are apt and amusing quotes at the start of each; the section on authority has Ambrose Bierce (1911), "Accountability is the mother of caution." Interspersed with the text in the chapters are boxes titled, "when policy meets reality" which give surprising and informative examples; some are worthy of "news of the weird" such as the theft of two 40 ton locomotives in the risk management and insurance chapter. Each chapter has its own references, explanatory and summary tables, and relevant examples of actual policies in use by various institutions. At the end of the book are appendices including a glossary, a section on laws and regulations, and an expanded list of resources; the bibliography is thorough, the online references less so because a couple of years have passed since publication.

The book was designed as a textbook for Museum Studies graduate students. It seems to be geared particularly to natural history collections although there are plentiful examples from the art world. While I was disappointed to note that zoos are conspicuous by their absence I found that virtually all of the issues are the same and thus the book can be extremely useful to those with living collections.

Anyone who has stewardship responsibilities or deals with collections in institutions would profit from reading—and applying—this book.

Graziano and Reid (2006) reported a range extension of the Seal Salamander (*Desmognathus monticola*) into southern Ohio (Adams County, Monroe Township), the first documentation of the species north of the Ohio River (Pfingsten and Matson 2003). The species verification was made from two specimens collected from two seepages where the closely related *Desmognathus fuscus*, the Northern Dusky Salamander, also was present. No morphological information was provided for either of the specimens, nor was there any discussion of the characters used to distinguish them from the coexisting *D. fuscus*.

Due to the importance of this possible new addition to the herpetofauna of Ohio, and given that the Ohio Department of Natural Resources is now undertaking a major revision of the status of salamanders in the state, we report our collective findings of a reexamination of the two specimens collected by Graziano and Reid (2006). The specimens were deposited at the Fort Hays State University Sternberg Museum of Natural History and were assigned catalog numbers MHP-H 12169 and MHP-H 12170. Both individuals are males with standard lengths (snout-posterior vent lengths) 66.5 and 53.2 mm, respectively.

Both specimens collected by Graziano and Reid are patterned with a dorsal stripe that is most evident posterior to the front legs, a character reported by Hulse et al. (2001) to be lacking in *D. monticola* from Pennsylvania (Fig. 1). Neither specimen has the deeply cut "bold, dark wormy marks" on the dorsum and/or tail that are characteristic of *D. monticola* we have observed and were reported by Petranka (1998). The venter of one of the specimens (MHP-H 12169) has pigmentation with evidence of a reticulate pattern beginning to form, a characteristic of *D. fuscus* as they age. One of us (RAP) has searched for *D. monticola* in southern Ohio counties north of the Ohio River and has collected individuals in Adams County thought to be *D. fuscus* with a dorsal pattern similar to the Graziano and Reid specimens. A "*monticola* like" dorsal pattern has been observed by one of us (RDD) in *D. fuscus* populations from northern Ohio (Lake County), approximately 160 km from the closest known *D. monticola* records in western Pennsylvania (Hulse et al. 2001). From our external examination of the specimens collected by Graziano and Reid (Fig. 1), we find no compelling evidence to suggest that either is *D. monticola*.

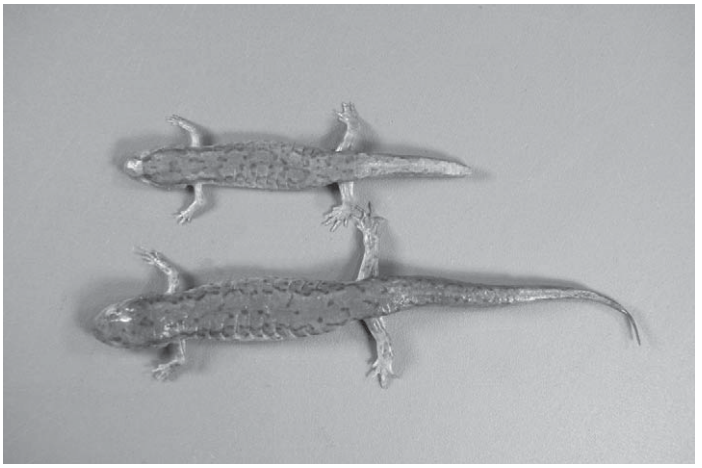

FIG. 1. Specimens of Graziano and Reid (2006) collected from Adams County, Monroe Township, Ohio. Top is Sternberg Museum of Natural History (MHP) 12169, bottom is MHP 12170.

However, because there can be extreme intraspecific variation in morphology, color, and pattern in the genus *Desmognathus*, we also examined tooth morphology and toe pads as presented by Caldwell and Trauth (1979). They report differences in tooth morphology between *D. fuscus* and *D. monticola* from the posterior half of the dentary that can be used to help distinguish the two species. Figure 1 in Caldwell and Trauth (1979) shows *D. monticola* collected from Kentucky having a pointed and piercing-type tooth crown in the posterior half of the dentary, with the lingual cusp being much higher than the labial cusps. In contrast, the crown is blunt and relatively flat in *D. fuscus* with lingual and labial cusps approximately equal in height.

We compared the tooth morphology of the two specimens collected by Graziano and Reid with those presented in Caldwell and Trauth (1979) with two additional specimens in the collection of the Cleveland Museum of Natural History; CMNH 3307, a *D. fuscus* collected by RAP from Adams County, Ohio very near the collection sites of Graziano and Reid; CMNH 6020, a *D. monticola* collected by RAP from Wayne County, West Virginia. We examined teeth from the most posterior region of the dentary from all four specimens at 150x magnification using a Zeiss Discovery V12 stereomicroscope with photographic capability.

The tooth morphology of the specimens we examined is presented in Fig. 2. The Graziano and Reid specimens (B and C in Fig. 2) have teeth nearly identical to those of the CMNH 3307 (A in Fig. 2), the *D. fuscus* from Adams County, Ohio. Differences in length and width of teeth may be related to sex, age, or some other factor. Neither specimen collected by Graziano and Reid has teeth that are consistent with CMNH 6020 (D in Fig. 2), the *D. monticola* collected from West Virginia nor those collected from Kentucky (fig. 1 of Caldwell and Trauth 1979).

Caldwell and Trauth (1979) also discuss differences in pigmentation of toe pads (friction pads) between *D. monticola* and *D. fuscus*.

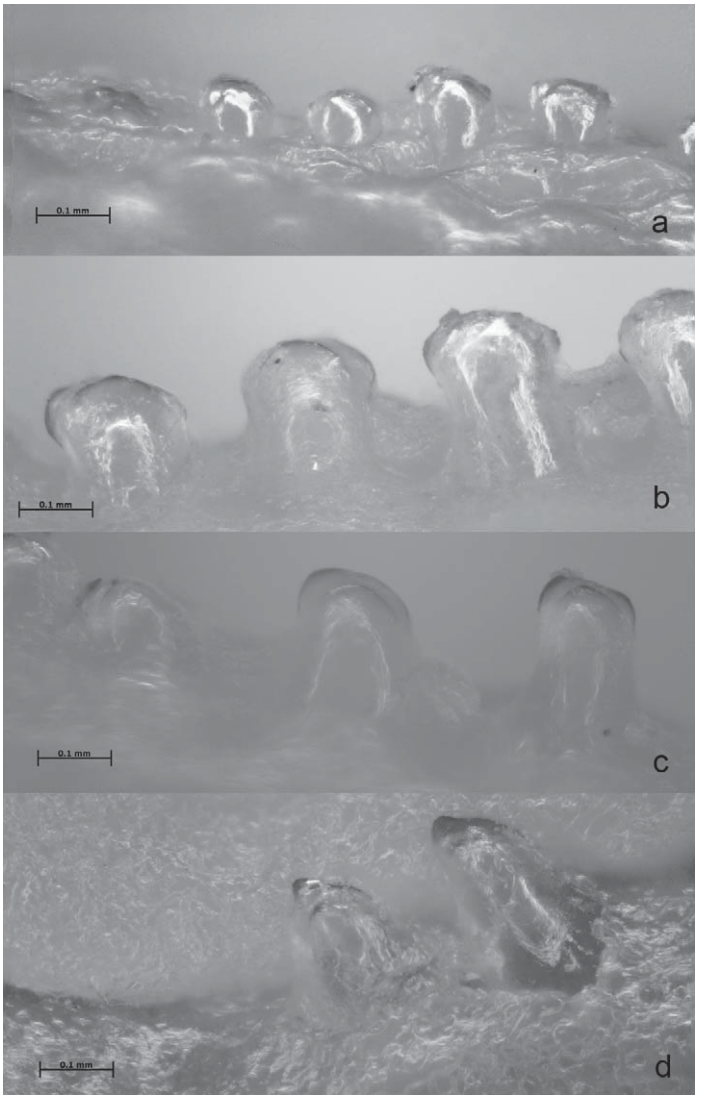

FIG. 2. Tooth morphology from the most posterior region of the dentary of four *Desmognathus* specimens. Label A = *D. fuscus* female from Adams County, Ohio from the collection of the Cleveland Museum of Natural History (CMNH 3307); Label B = MHP 12169 of Graziano and Reid (2006), a male; Label C = MHP 12170 of Graziano and Reid (2006), a male; Label D = *D. monticola* from Wayne County, West Virginia (CMNH 6020), sex undetermined. Both specimens of Graziano and Reid (2006) have teeth nearly identical to those of the cataloged *D. fuscus*.

They report that *D. fuscus* examined from Kentucky (N = 119) was never found to possess friction pads with dark pigmentation at the tip of the toes. If pigmentation was present at the toe tip, it was not significantly darker than surrounding tissue. In contrast, they found dark friction pads were present on at least some of the toes in 94.4% of *D. monticola* examined from Kentucky (N = 62). No evidence of ontological variation was found with dark pigmentation evident in larvae as well as large adults. Our microscopic examination of the 20 total digits of the two specimens of Graziano and Reid (2006) revealed no evidence of dark pigmented friction pads differing from the surrounding tissue. While this character alone is not taxonomically conclusive, we find no evidence of friction pads on the toes of the Graziano and Reid specimens suggesting they are *D. monticola*.

In summary, we conclude from our reexamination of the two Graziano and Reid specimens that they both have attributes of body color and pattern, tooth morphology, and friction pads on the toes that are indicative of *D. fuscus* found in the state of Ohio. We consider this published range extension to be untenable and cannot support recommending that it be used to include *D. monticola* to the list of herpetofauna of Ohio.

Acknowledgments.—We thank the Ohio Department of Natural Resources Division of Wildlife for granting permission to us to examine the two putative specimens of *Desmognathus monticola*. We thank Steve Tilley and Kenneth Wray for providing helpful comments leading to improved readability of the manuscript.

Living Reptiles and Amphibians Available from Smithsonian National Zoological Park, Washington DC

The following are available gratis to qualified non-profit institutions: nature centers, living material centers, and academic institutions:

Gonyosoma oxycephala, adult female, (Red Tailed Rat Snake)
Tiliqua scincoides, 2 adult females, (Blue-tongued Skinks)
Elaphe obsoleta rossalleni, 2 adult males, 1 adult female, (Everglades Rat Snakes)
Eublepharis macularius, group of five adults, (Leopard Geckos)

Some of the specimens are habituated long-term captives and could be used for demonstrations. Potential recipients will undergo a review process. Shipping costs must be borne by recipient.

If interested, contact curator James B. Murphy for additional details: Department of Herpetology, Smithsonian National Zoological Park, PO Box 37012 MRC 5507, Washington DC 20013-7012; e-mail: murphyj@si.edu; cell phone: 202-327-3767.

**Corresponding authors*

Among Mexico's diverse herpetofauna, the rattlesnakes (*Crotalus* and *Sistrurus*) have intrigued both herpetologists and non-herpetologists alike for centuries. One group of rattlesnakes, however, has remained especially enigmatic. The long-tailed rattlesnake group includes three rare species (*C. stejnegeri*, *C. lannomi*, and *C. ericsmithi*) and is represented in museum collections by fewer than 15 specimens, most of which are *C. stejnegeri* (Campbell and Flores-Villela 2008; Campbell and Lamar 2004). Their unique body structure and unusually long tails have raised numerous questions regarding their natural history and ancestry.

The Autlán Long-tailed Rattlesnake, *C. lannomi*, has been known only from a single specimen, collected in June 1966 by Joseph R. Lannom, Jr. from "1.8 miles west of the pass: Puerto Los Mazos, Jalisco" (Tanner 1966). Despite numerous attempts to locate additional specimens (Campbell and Flores-Villela 2008; Campbell and Lamar 2004), none have been reported since the initial description.

Since 2004, we have searched for rattlesnakes in the western foothills of the Sierra Madre Occidental and associated ranges in Nayarit, Jalisco, and Colima. Over the course of several weeks in July 2008, five additional specimens of long-tailed rattlesnakes were found in the foothills of Colima, México. Based on features of lepidosis, this new material is referred to *Crotalus lannomi*. The snakes were found approximately 50 km SW of the type locality (Fig. 1). Herein, we provide detailed morphological descriptions of the new specimens, notes on natural history, comparisons with the other species of long-tailed rattlesnakes, and review the conservation status of the species.

Methods

The new specimens of *Crotalus lannomi* were collected at two localities in Colima: 42 km SE (Site 1) and 48 km ESE (Site 2) by road from Cuautitlan, Jalisco (Fig. 1). Protocols for making scale counts and definitions of external morphological features follow Klauber (1972) and Campbell and Lamar (2004). Measurements were made using a meter stick to the nearest 1 mm or with a digital caliper. All specimens were photographed by digital camera (Nikon D200 and Sony Cyber-Shot F828) and the images were deposited at the University of Texas at Arlington Digital Image Collection (UTADC). One specimen was deposit at the Museo de Zoologia, Facultad de Ciencias, UNAM (MZFC 22941).

Measurements for other species of long-tailed rattlesnakes were taken from published sources (Campbell and Flores-Villela 2008; Campbell and Lamar 2004; Dunn 1919; Tanner 1966).

Results

Description of the new material.—The specimens of *Crotalus lannomi* reported herein (N = 5; 3 males, 2 females) agree in most characters with the original description by Tanner (1966). A comparison of morphological characters is given in Table 1. The following is a summary of scutellation in *C. lannomi*: rostral wider

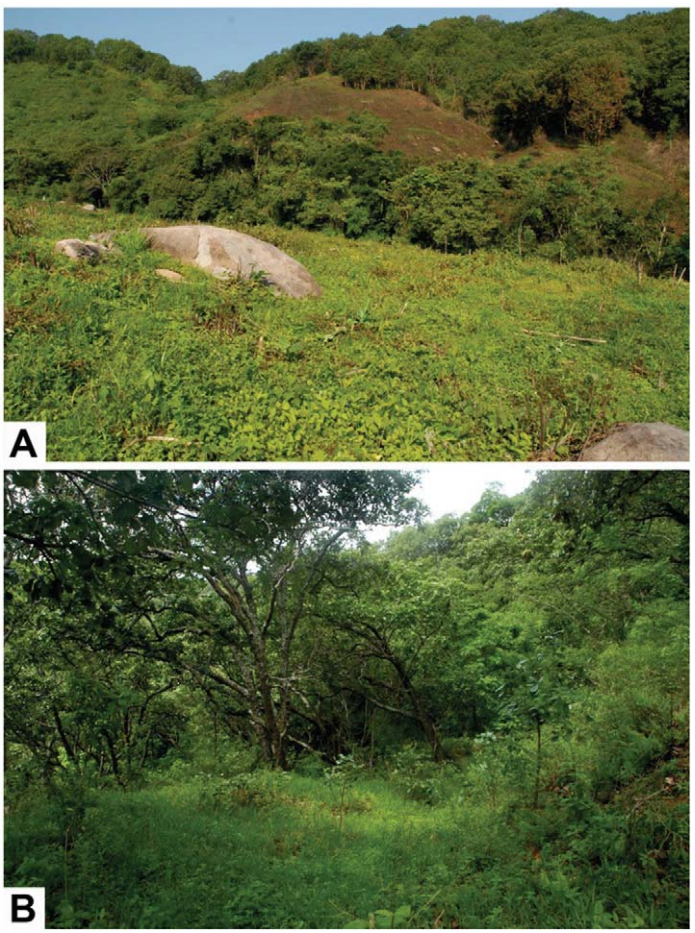

Fig. 1. New localities for *Crotalus lannomi* in Colima, Mexico. A) 42 km by road SE of Cuautitlan, Jalisco. Cleared field in open oak/TFD ecotone, 805 m elevation. B) 48 km by road ESE of Cuautitlan, Jalisco. Steep hillside in open oak/TDF ecotone, 1150 m elevation.

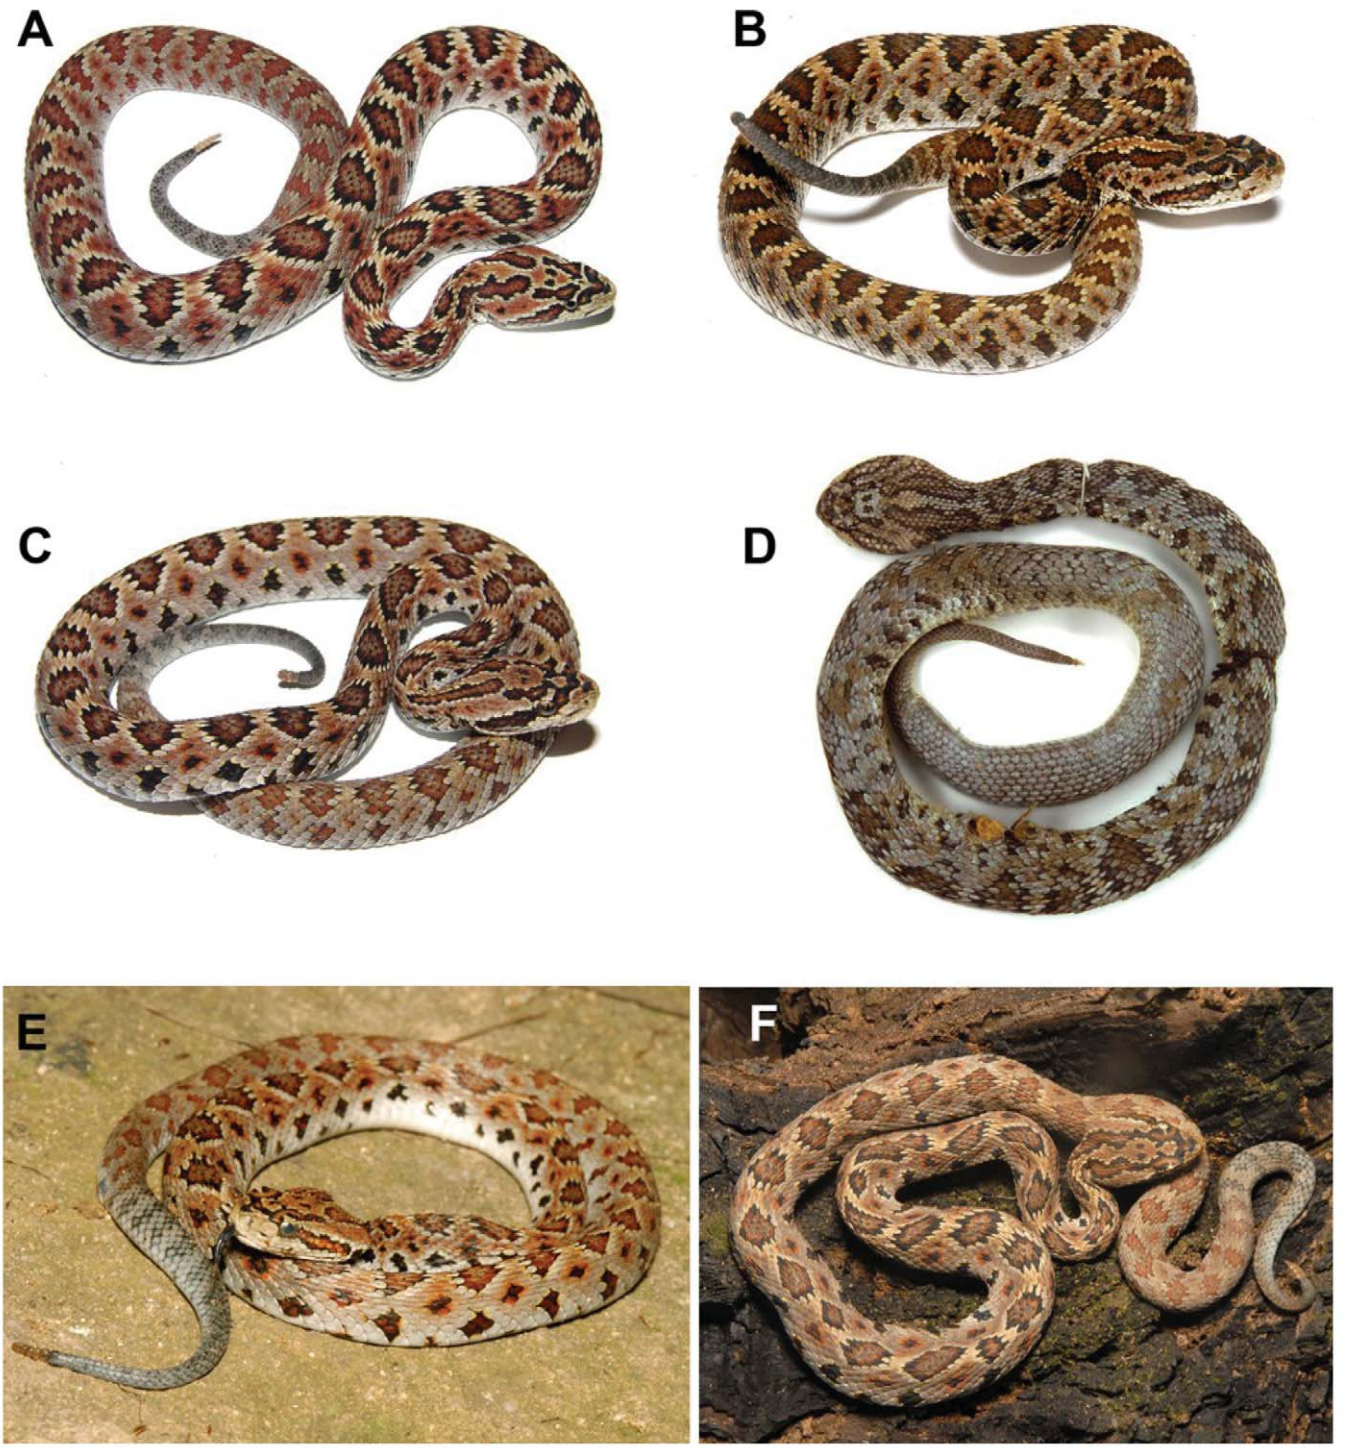

FIG. 2. Known specimens of *Crotalus lannomi*: A) UTADC-4005, female; B) UTADC-4002, female; C) UTADC-4003, male; D) BYU-23800, female, holotype; E) MZFC-22941, male; F) UTADC-4006, male.

than high; canthals moderate to large; 2–4 scales between canthals (but in two specimens canthals in contact); internasals relatively narrow; intersupraoculars 3, 4, or 5 at midlevel; 1–4 scales between intersupraoculars and intercanthals; dorsal scale rows (DSR) extremely variable: midbody 25–29; one head length behind neck 23–27; one head length anterior to cloaca 20–22; ventrals 168–175; subcaudals in males 49; in females 35–36; body slender in both sexes though slightly more stout in females.

Coloration.—In life coloration is as follows: ground color varies from rust-red to various shades of brown and yellow; dorsal blotches 31–35 (31–33 in females, 35 in males); blotches brown with central highlights and dark black or dark brown edges surrounded by a pale cream or white border one scale in width; blotches fade to pale brown or rust with the dark edges and pale border becoming indistinguishable towards the posterior part of the body; primary dorsal blotches 3–10 scales wide and 2–11 scales

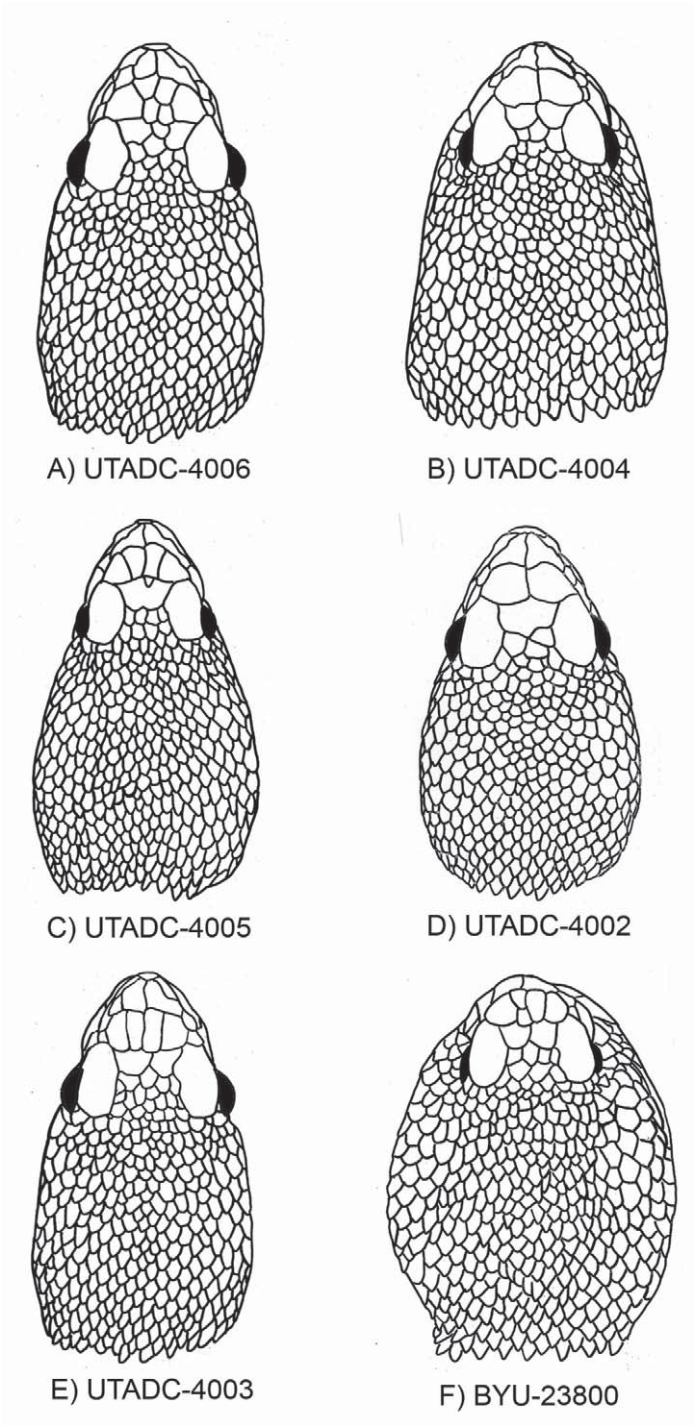

FIG. 3. Head scalation of *Crotalus lannomi*: A) UTADC 4006, male; B) MZFC 22941, male; C) UTADC 4005, female; D) UTADC 4002, male; E) UTADC 4003, female; F) BYU 23800, female, holotype (the unusual appearance can likely be attributed to the snake being run over by a vehicle).

long (9–12 scales wide and 3–5 scales long in the holotype), narrowing towards the posterior of the body; blotches separated by 0.5–4 scales; a dark brown or black spot present on both sides of each dorsal blotch, on scales 2–4; spots become paler on the posterior part of the body; a small dark lateral spot is present, usually on scale rows 4–6 between dorsal blotches, bordered by bright orange on surrounding scales; a secondary row of smaller dark lateral spots is present just above the ventrals; tail pale blue-gray, with 12–17 gray bands; venter white with an irregular series of two black spots near the margin of each ventral. In preservative most colors turn dull gray or brown.

Habitat.—Both new localities for *Crotalus lannomi* reported here are within an ecotone of tropical deciduous forest (TDF) and oak forest (Fig. 1). The area is characterized by wet canyons harboring tropical semi-deciduous forest with large old growth trees. Areas above 1200 m have medium to dense pine or pine-oak forest. Site 1, at 805 m elev., lies along an arroyo and consists of a cleared field with scattered large boulders, covered by grasses and secondary growth ca. 0.5–1 m high. It is bordered by open oak/TDF (Fig. 1A). Site 2 is a steep hillside in open oak/TDF located at 1150 m elev. (Fig. 1B). It is mostly undisturbed, with the exception of some light grazing and logging. Introduced grasses (*Panicum, Hyparrhenia, Andropogon*) and small bushes represent the principal vegetation cover at Site 1. Small bushes (*Montano* sp., *Verbesina* sp.) and some herbaceous plants (*Adiantum* sp., *Cheilanthes* sp., *Hemiontis* sp.) form the understory at Site 2. Oak trees (*Quercus magnolifolis, Q. iltisii, Q. elliptica*) and tropical arborescent species (*Bursera bipinnata, Cecopia* sp., *Lysiloma* sp., *Sapium* sp.) represent the principal tree species at both localities.

NATURAL HISTORY

Diet.—Examination of fecal samples from a juvenile specimen (UTADC 4003) revealed lizard scales (*Sceloporus* sp.), arthropod remains, plant matter, and the mandible of a colubrid snake. The colubrid mandible measures 2.3 mm in length and has two posterior fangs with deep grooves.

Reproduction.—Umbilical scars were present in the two juvenile specimens (UTADC 4002, 4003), both of which were found ca. 20 m apart on the same hillside at Site 1 on 15–16 July, respectively. An adult female and male (UTADC 4005, 4006) were found on 24 July 2008 basking together beneath grasses and small ferns at Site 2 (Fig. 1B). The previous day, a single male (MZFC 22941) was observed at this site.

Activity and behavior.—All specimens were found partially hidden beneath vegetation between 1130 and 1300 h, and were quick to rattle and retreat when disturbed. None assumed a defensive posture nor struck when handled. We spent many hours actively searching at night, both in the field and on roads, but were not able to locate any specimens. However, based on published observations of related taxa (Campbell and Flores-Villela 2008; McDiarmid et al. 1976a), we expect this species to be crepuscular and/or nocturnal when weather permits.

DISCUSSION

Comparison with other long-tailed rattlesnakes.—The paucity of specimens available for study coupled with minimal sampling over a wide geographic range has made it difficult to determine relationships within this group. Until now, two of the three species (*C. lannomi* and *C. ericsmithi)* were each known only from a single specimen. Although the specimens reported here add to our understanding of variation in *C. lannomi* (Table 2), further sampling within the expected collective range of the long-tailed species group is needed to confirm the distinctiveness of the cur-

TABLE 1. Morphological variation in *Crotalus lannomi*. Measurements for BYU 23800 were taken from Tanner (1966) and Campbell and Flores-Villela (2008). DSR = Dorsal Scale Rows.

rently recognized species.

Coloration of *C. lannomi* is very similar to that of the type specimen of *C. ericsmithi*. The bright orange color of *C. ericsmithi* was one of the most distinctive characters reported in the original description (Campbell and Flores-Villela 2008). Both adult male specimens of *C. lannomi* reported here also display bright orange to reddish coloration (Fig. 2). *Crotalus stejnegeri* is significantly duller in color, although Campbell and Flores-Villela (2008) noted that some specimens had orange-colored scales.

The additional specimens of *C. lannomi* demonstrate that this species is also highly variable in scutellation (Table 1). Previous differences thought to distinguish *C. lannomi* from *C. ericsmithi* have proven unreliable, including size of canthals, number of scales between canthals, number of intersupraoculars, number of ventrals, and general head and body coloration, as all of these characters overlap considerably between the two species. The number of mid-dorsal body blotches was believed to be a distinguishing feature between *C. lannomi* and *C. stejnegeri*. The additional material described here, however, demonstrates an overlap in all three species. *Crotalus lannomi* was believed to have a more stout body than *C. ericsmithi* and *C. stejnegeri*, but this trait seems to be a sexually dimorphic condition unique to females. Conversely, we have found the following characteristics to be useful in distinguishing *C. lannomi* from the other two species of long-tailed rattlesnakes: a reduced number of scales between the intersupraoculars and intercanthals, numbering 1–4 (12 in *C. ericsmithi*, more than 10 in *C. stejnegeri*) and by having fewer prefoveals, 4 (7–8 in *C. stejnegeri;* 5–6 in *C. ericsmithi*). The first pair of infralabials is mostly separated by the mental in *C. ericsmithi*, while it is in broad contact in both *C. lannomi* and *C. stejnegeri*.

Although each of the three species of long-tailed rattlesnakes occupies a very small area, their ranges are undoubtedly far greater than presently understood (Fig. 4). All three species occur at similar elevational and vegetation associations, and in similar climate zones that can be found almost continuously along the western slopes of the sierras from northwestern Durango to Oaxaca. Here we suggest some specific areas for future field efforts, as new material from within range gaps will be important in resolving relationships within the group.

1. The coastal foothills of Guerrero and Oaxaca, south of the low pass of the Sierra Madre del Sur, located near Chilpancingo.

2. The Sierra de Coalcomán in coastal Michoacán is located between the ranges of *C. lannomi* and *C. ericsmithi* and it seems likely that at least one of these species occurs there.

3. Also warranting attention is the Balsas/Tepalcatepec Basin of Jalisco, Michoacán, México, Guerrero, and Morelos, where a humid tropical semi-deciduous forest appears on the southern slopes of the central transverse ranges.

4. No species of long-tailed rattlesnake has been reported from Nayarit, however the state likely has *C. stejnegeri* and potentially *C. lannomi*.

5. Another area of interest is the region where the states of Sonora, Sinaloa, and Chihuahua meet, where we have heard rumors of long-tailed rattlesnakes from east of Álamos, Sonora and near Cosalá, Sinaloa.

Although it is unclear why no additional specimens of *Crotalus lannomi* had been found since the original description, and why long-tailed rattlesnakes in general are so seldom found, the following factors undoubtedly serve to reduce collecting efforts in long-tailed rattlesnake habitat.

TABLE 2. Morphological variation in long-tailed rattlesnakes. Measurement for *Crotalus ericsmithi* and *C. stejnegeri* were taken from Campbell and Flores-Villela (2008).

Characters	*Crotalus lannomi*	*Crotalus stejnegeri*	*Crotalus ericsmithi*
Tail % of TL	Males, 12.7–14.4% Females, 9.3–10.8%	Males, 10.4–14.5% Female, 9.7%	Male, 15.9%
Internasals	Relatively narrow	Broad	Relatively narrow
Size of canthals	Moderate to very large	Moderate	Large
Scales between canthals and intersupraoculars	0–4 3–5	2–3 5–8	3 5
Scales between intersupraoculars and intercanthals	1–4	>10	12
Ventrals	Males, 171–175 Females, 168–175	Males, 172–178 Females, 171–176	Male, 172
Subcaudals	Males, 49 Females, 35–37	Males, 48 Females, 36–37	Male, 41
Dorsal body blotches	Males, 35 Females, 31–33	34–43	35

Social issues.—The narrow band of habitat where long-tailed rattlesnakes are found is favorable for marijuana and opium production (pers. obs.). The type locality of *C. stejnegeri*, for example, has a long history of drug-related violence, as does Mexican Hwy 40, where additional specimens of that species have been collected (Hardy and McDiarmid 1969; McDiarmid et al. 1976). The coastal sierra of Guerrero, the only known locality for *C. ericsmithi*, is an important center for narcotics production, as is the Sierra de Coalcomán in Michoacán. In general, the western sierras of Nayarit, Jalisco, and Colima are somewhat less affected, but still have areas of marijuana and opium poppy harvesting.

Roads.—There are few accessible roads through long-tailed rattlesnake habitat. There are between four and eight paved roads traversing areas inhabited by long-tailed rattlesnakes, several of which are some of the most dangerous in Mexico. Aside from poor road conditions, domestic livestock, heavy fog, rain and flooding, treacherous curves, and dangerous traffic, highway robberies and kidnappings are not uncommon. Access on dirt roads is more widespread; however, navigating them during the rainy season can be near impossible.

Conservation of Crotalus lannomi**.**—The tropical foothills of Colima, where the additional specimens of *C. lannomi* were found, are some of the state's last remaining wilderness areas, as most of the lowlands have been severely altered by human activity. Issues affecting the conservation of *C. lannomi* have not been studied, but here we list anthropogenic factors potentially affecting *C. lannomi* habitat:

• Agriculture.—Corn and coffee are being cultivated with some

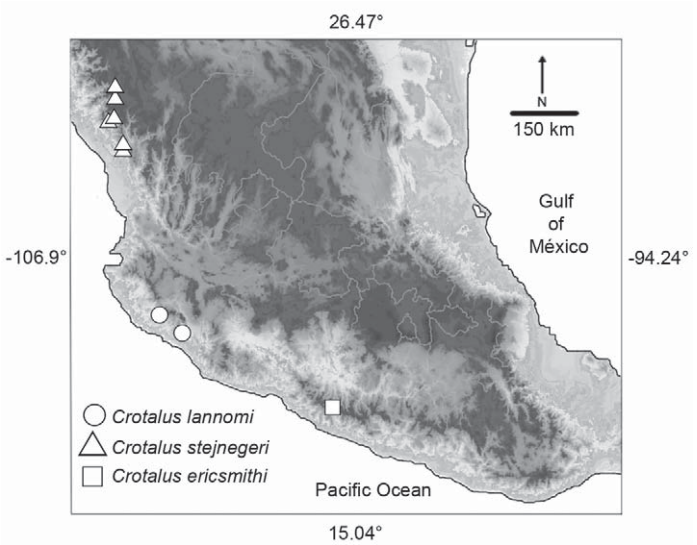

FIG. 4. Distribution of species of the long-tailed rattlesnake group in western Mexico.

frequency at Site 1. However, general inaccessibility and rough terrain limit the threat to most of this area.

• Cattle grazing.—Small-scale cattle grazing is common at both sites. Animals are usually free ranging and feed on native vegetation and introduced grasses. Some hillsides are considerably eroded, presumably due to overgrazing.

• Logging.—Minimal logging for charcoal production occurs in the vicinity of both localities.

• Mining.—Several active ore mines are found throughout the known and predicted range of *C. lannomi*. The expansion of these mining operations represents a potential risk to *C. lannomi* and its habitat.

Crotalus lannomi is listed as threatened by the Secretaría de Medio Ambiente y Recursos Naturales (SEMARNAT). This is equivalent to the vulnerable category as defined by the IUCN. Although these rankings are assumed to be similar, this species is listed as "data deficient" in the IUCN Red List of Threatened Species (Ponce-Campos and Garcia-Aguayo 2007) rather than vulnerable. We consider *C. lannomi* vulnerable throughout its very limited known range.

Several species of unique plants and animals share the habitat with *Crotalus lannomi*. The tree *Inga colimana* (Fabaceae) is endemic to the area (Padilla Velarde et al. 2005). The Peregrine Falcon (*Falco peregrinus*) is known to nest at similar elevations in western Colima (Santana et al. 2006). This represents the southernmost reported nesting site for the species. At least one Puma (*Puma concolor)* was observed while searching for snakes at night. Some 716 species of plants are reported from a nearby sierra, and of those, 16 are considered to be in some kind of risk category and two are endangered (Padilla-Velarde et al. 2008). We believe that the west-central foothills of Colima should be protected to ensure the conservation not only of *Crotalus lannomi* but the rich flora and fauna sharing its habitat. Further studies are necessary to understand the ecology and natural history of this elusive species and to promote its conservation.

Type locality of Crotalus lannomi.—After an interview with Joseph R. Lannom, Jr. (interviewed by JRV on 6 February 2009), collector of the holotype of *C. lannomi*, it seems likely that the original locality reported in Tanner (1966) is in error. During the interview, Lannom described the type locality of *C. lannomi* as a bridge where the highway crosses a lush canyon, which he referred to as "Wildcat Canyon." A canyon fitting his description, known locally as "Arroyo el Tigre" is located at 550 m elevation, 12 km SW by road from the locality given in Tanner (1966). This locality lies within the TDF/oak forest ecotone. This difference might explain why searches at the published type locality, situated in a more arid oak forest, have failed to produce additional specimens.

Common name of Crotalus lannomi.—Tanner (1966) suggested the name "Autlán Rattlesnake" for *C. lannomi*. This name was later changed to "Autlán Long-tailed Rattlesnake" by Campbell and Flores-Villela (2008). The city of Autlán de Navarro, Jalisco, is located a short distance from the type locality of *C. lannomi* (ca. 13 airline km NE), but boasts habitat and climatic conditions significantly different from those at all known collection sites. The city is located in the rain shadow of the Sierra Manantlán, and the habitat is a dry, desert-like thornscrub. We believe it unlikely that *C. lannomi* would inhabit the area surrounding the city of Autlán, and therefore consider the name "Autlán Long-tailed Rattlesnake" inappropriate for this species. Given that both the type locality and the abovementioned collection sites are located in, or associated with, the Sierra de Manantlán, we propose the name "Manantlán Long-tailed Rattlesnake" for *C. lannomi*.

Herpetofauna associated with Crotalus lannomi.—A number of amphibians and reptiles were found at or in proximity to the new localities given here for *Crotalus lannomi*. Table 3 summarizes the herpetofaunal species found at these localities. Most are typically lowland inhabitants, but several (*Elgaria kingii*, *Sceloporus bulleri*, *Exerodonta smaragdina*, and *Hyla arenicolor*) are mid-elevation or highland species in west-central Mexico.

Acknowledgments.—We thank Joseph R. Lannom, Jr. for his insight and most of all for finding the first specimen of *Crotalus lannomi* over 40 yrs ago, which started this quest. We thank Oscar Avila-Lopez, Alexander Hermosillo, Chris Rodriguez, Ana Pacheco, Loreli Nuño, and R. Michel for their assistance in the field. We also thank Jonathan Campbell, Robert Bryson, Carlos Ibarra, Juan Rodriguez, and Jeff Streicher for their support. Special thanks to Oscar Avila and Francisco Santana for identifying some of the plant species at the new localities. Jonathan Campbell, Robert Bryson, Jesse Meik, and Dan Mulcahy kindly reviewed previous versions of the manuscript. Joseph Collins provided the image of the *C. lannomi* holotype. We are deeply indebted to the Michel family, as well as to Leo and Roman for all of their help and hospitality. We are also especially thankful to Oscar Flores for his assistance in reviewing this manuscript. Fieldwork was conducted under a collecting license issued to Oscar Flores by SEMARNAT (FAUT-0015). We gratefully acknowledge the support of Ronald A. Javitch, Montreal, for making possible the publication of color plates.

Checklist of Terrestrial Reptiles in Three Protected Areas in the Kingdom of Saudi Arabia

PETER L. CUNNINGHAM
King Khalid Wildlife Research Centre, Thumamah
P. O. Box 61681, Riyadh, Kingdom of Saudi Arabia
and
Zoological Society of London, Conservation Programmes
Regent's Park London, NW1 4RY, United Kingdom
e-mail: pckkwrc@yahoo.co.uk

Because of under-collecting and general understudy, there is an overall paucity of data for reptiles in the various protected areas within the Kingdom of Saudi Arabia. Reptile species lists of occurrence (i.e., inventories of species occurring in protected areas or specific conservation areas) have not been published for the Kingdom of Saudi Arabia. However, a provisional checklist for the Mahazat as-Sayd protected area was published by Gaucher and Asmodé (1991). Previous general checklists for the region include Arnold (1986a) [lizards and amphisbaenians], Gasperetti (1988) [snakes]; Hillenius and Gasperetti (1984) [chameleons]; Gasperetti et al. (1993) [turtles], with general publications including reptiles from the Gulf Region by Leviton et al. (1992). Most recently, Egan (2007) published a field guide on the snakes of the Arabian Peninsula. General species-focused publications are more numerous with a number of reptile publications by various authors in the volumes of the Fauna of Saudi Arabia dating from 1979 onwards.

Study area.—A survey using a comprehensive literature review as well as confirmed sightings was conducted for three protected areas (Mahazat as-Sayd, Uruq Bani M'arid and the King Khalid Wildlife Research Centre – Latin transliteration of Arabic follows Child and Grainger 1990) within the Kingdom of Saudi Arabia (Fig. 1). These three areas are described individually:

1. The **Mahazat as-Sayd Protected Area** is a flat, arid desert steppe located ca. 150 km NE of Taif and 700 km W of Riyadh in western central Saudi Arabia (28.25°N, 41.67°E, between 900 and 1100 m above sea level) covering an area of 2190 km^2 (Child and Grainger 1990). The climate is arid with the annual rainfall (occurring mainly between March and May) highly variable ranging between 50 and 100 mm and the mean monthly minimum and maximum temperatures ranging between 2 and 21°C and 29 and 40°C (Islam et al. 2007). The general area is undulating sandy and gravel plains with shallow stony, often saline, soils with a low organic content and low levels of nitrogen, phosphorous, and potassium (Child and Grainger 1990) and dominated by *Acacia tortilis* trees and *Salsola spinescens* shrubs (Combreau and Rambaud 1994).

2. The **Uruq Bani M'arid Protected Area** is located ca. 750 km SW of Riyadh and 250 km N of Najran bordered on its west by the southernmost extension of the Tuwaiq Escarpment, a remnant Jurassic limestone massif, and to the east by the extensive sands (mainly longitudinal dunes) of the notorious Rub' al-Khali (Empty Quarter), the largest sand sea in the world. The overall size is 12,500 km² (core area 5000 km²) and the entire area is sparsely vegetated (19.13°N, 45.13°E, between 720–940 m above sea level) (Child and Grainger 1990). Trees, mainly *A. tortilis* and *A. ehrenbergiana*, occur in the interdune troughs (*shiqqat* in Arabic) and extend for only a short distance from the escarpment. Dune soils are windblown, sandy and loose with the desert pavement areas (interdune troughs) having high exchangeable sodium content and often saline (Child and Grainger 1990). The rainfall is highly variable and low with a mean of less than 47 mm annually, consequently with the lowest plant growth after the Empty Quarter within Saudi Arabia (Dunham 1997).

3. The **King Khalid Wildlife Research Centre (Thumamah)** is located approximately 70 km N of Riyadh in central eastern Saudi Arabia. The limestone Tuwaiq Escarpment borders the area towards the east with sandy-gravel plains and a belt of sand dunes towards the west (25.217°N, 46.617°E, at 600 m above sea level) (Child and Grainger 1990). Plateau soils (of which the gravel plains are part) are shallow and stony, often saline and with a low organic content

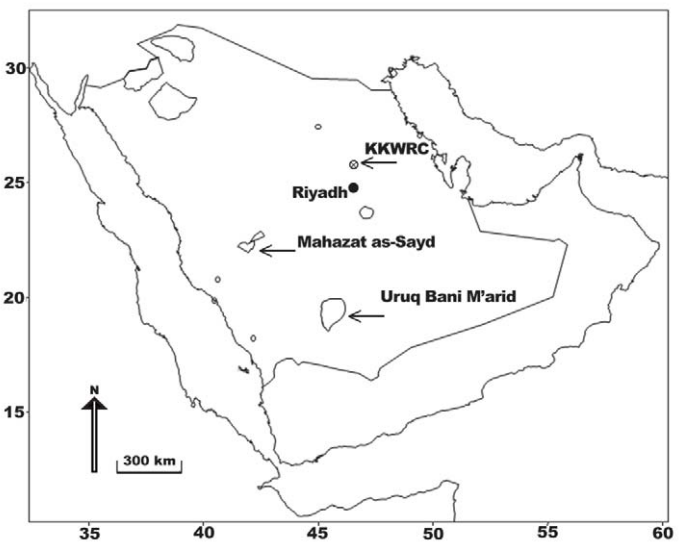

FIG. 1. Map of the Kingdom of Saudi Arabia, indicating the protected areas where the surveys were conducted.

TABLE 1. Checklist of reptiles expected, confirmed or presence unclear in three protected areas in the Kingdom of Saudi Arabia. [1]Identified as *Trapelus mutabilus* by Tilbury (1988) from the Riyadh area; [2]According to Arnold (1986a) this species only occurs in north-western Saudi Arabia although Tilbury (1988) recorded it from the Riyadh area; [3]Found in the Dhana area, east of Riyadh (Leviton et al. 1992; Tilbury 1988); [4]Known only from the Al-Kharj area south of Riyadh (Leviton et al. 1992). Reptiles expected from the above mentioned protected areas (general areas) were determined using references to distribution (site localities) and distribution maps by [a]Arnold (1986a), [b]Gasperetti (1988), [c]Tilbury (1988), [d]Leviton et al. (1992), [e]Disi et al. (2001) and [f]Egan (2007). Confirmed sightings using species characteristics include my own observations as well as the provisional checklist by [g]Gaucher & Asmodé (1991) (for Mahazat as-Sayd) and personal records from M. Grobler, E. R. Robinson, M. Sher Shah, H. Tatwani (pers comm.).

and low levels of nitrogen, phosphorous and potassium (Child and Grainger 1990). The vegetation is dominated by shrubs such as *Ranterium eppaposum* and *Haloloxylon salicornicum* and the grasses *Panicum turgidium* and *Stipagrostis plumosa*. The overall size is 350 km² (fenced) with the KKWRC fenced enclosure within this being approximately 20 km². The rainfall is highly variable and a long-term average of 117 mm per annum has been recorded since 1989/1990 (Robinson 2007).

Methods.—Sampling was done primarily on an *ad hoc* basis while conducting fieldwork on the ecology of the Arabian Sand Gazelle (*Gazella subgutturosa marica*) in the various protected areas, and was not quantitative, thus no attempt at estimating the abundance of species. Consequently, the sampling intensity (i.e., amount of time spent in each protected area including time spent searching for reptiles) varied between protected areas. Sampling was conducted from January to November 2008, with most of the recordings occurring during the warmer months from March to September. Nocturnal observations were made using vehicle headlights while travelling slowly on tracks throughout the areas or on foot using a gas lantern. Individuals were photographed *in situ* or captured by using an extendable fishing rod and noose and photographed for confirmation and identified to species level using a variety of literature available or consulting regional experts listed in acknowledgments. Additional notes were made of the habitats in which each species was observed, and habits of some species were gathered to increase the knowledge regarding the ecology of reptiles within the protected areas. After confirmation of identification, all reptiles captured were released at the point of capture.

Results.—According to the available literature, a total of 52 species were expected to occur in the three protected areas although differences in distribution were expected between these areas due to different habitats. The highest reptile diversity was expected from the King Khalid Wildlife Research Centre, Thumamah area (40 species or 77% of the maximum total number of species expected from the 3 protected areas) followed by Mahazat as-Sayd (27 species or 52%) and Uruq Bani M'arid (18 species or 35%). Lizards dominated the expected reptile richness in the three protected areas (34 species or 65%) and included 7 agamas, 12 geckos, 7 lacertids, 7 skinks, and 1 varanid. Gekkonidae dominated the expected lizard richness (12 species or 35%). At least 17 species of snakes were expected in the three protected areas together (pooled) and included 1 Atractaspididae, 1 Boidae, 9 Colubridae, 2 Elapidae, 1 Leptotyphlopidae, 1 Typhlopidae, and 2 Viperidae. Colubridae dominated the expected snake richness (9 species or 53%) and 1 species of Amphisbaenia (*Diplometopon zarudnyi*) was expected.

The survey results confirmed 20, 15, and 6 species from the King Khalid Wildlife Research Centre, Mahazat as-Sayd, and the Uruq Bani M'arid protected areas, respectively. Furthermore (although not yet confirmed) at least another 23, 14, and 12 species are expected while the distribution for 9, 3, and 5 species is unclear in the King Khalid Wildlife Research Centre, Mahazat as-Sayd, and the Uruq Bani M'arid protected areas, respectively (Table 1).

Table 1 presents the reptiles that are expected to occur in the three protected areas as I concluded from Arnold (1986a), Gasperetti (1988), Leviton et al. (1992), Disi et al. (2001), Egan (2007), Tilbury (1988), and Gaucher and Asmodé (1991) and those confirmed by me or positively confirmed by co-researchers (e.g., personal records).

Discussion.—Much of the overall distribution of reptiles throughout the Arabian Peninsula is unknown. Data on even the basic ecology of many species is still lacking aggravating our limited understanding of ecosystem functioning. This preliminary, *ad hoc*, investigation into the biodiversity of reptiles in three protected areas highlights the lack of baseline information on the distribution for most species in Saudi Arabia. The presence of a number of reptiles in the protected areas is unclear but could be confirmed with increased collection and should be encouraged. The overall dry (drought) conditions throughout 2008 in all three protected areas certainly affected the reptile sightings and therefore no general comments are made on the abundance of species observed.

Species of notable conservation importance include *Uromastyx aegyptia* whose numbers have declined outside of protected areas due to illegal collecting for food or financial incentives (Sher Shah pers com). Very little is known about the distribution and status of endemics such as the skink, *Chalcides levitoni*, which is only known from one locality in the Al-Kharj area (Leviton et al. 1992)—i.e., a potential endemic to Saudi Arabia—ca. 50 km SE of Riyadh. Rapid development in the general area may negatively affect this species, but this would have to be investigated further. Although not recorded from the Thumamah area, the close proximity to Al-Kharj and lack of any contrary distribution data makes it a possibility. Another potential endemic is the gecko *Pristurus gasperetti gasperetti* now known only from two locations—Makkah area (Arnold 1986b) and Uruq Bani M'arid (this study). The generally unknown lacertid, *Acanthodactylus tilburyi*, has a disjunct distribution in Saudi Arabia with specimens known from the Riyadh area (Tilbury 1988) and Al Jawf in northwestern Saudi Arabia (Leviton et al. 1992). Such understudied species are important as development may decimate their populations before the basic ecology of these species can be elucidated. All snakes, due to a variety of reasons ranging from the obvious to the superstitious, are of concern as they are usually killed on sight. Except for two turtle species (Green and Hawksbill) listed under the IUCN's Red List of Threatened Species, no other reptile's conservation status is listed for Saudi Arabia (IUCN 2007).

Species newly identified for the respective protective areas—i.e., distribution not previously documented from the areas—include *Pristurus gasperetti gasperetti* from Uruq Bani M'arid (Cunningham 2008a), *Trapelus pallidus agnetae* from Mahazat as-Sayd (Cunningham 2008b), and *Trachylepis septemtaeniata* (formerly *Mabuya aurata*) from the Thumamah area (Cunningham 2008c). These sightings and confirmation of the species are viewed as range extensions for the Arabian Peninsula.

Although this publication reports on sporadic observation of reptiles from three protected areas only, it is expected to increase the knowledge of reptile distribution in these areas in Saudi Arabia and it is hoped that it would stimulate further research into this relatively understudied region. Such knowledge can be used to strengthen the importance of protected areas—i.e., indicating the importance of protected areas for overall biodiversity protection—as well as facilitate the holistic management of such areas in Saudi Arabia.

Acknowledgments.—I hereby acknowledge H. H. Prince Bandar bin Saud bin Mohammed Al Saud, Secretary General, NCWCD for his continued support towards conservation efforts in Saudi Arabia. My sincere appreciation goes to Andrew Gardner, Angelo Lambiris, Pritpal Soorae, and Yehudah Werner for assisting with literature and the identification of certain species. I also thank my colleagues Manie Grobler, Robbie Robinson, Moayyad Sher Shah, and Hani Tatwani for passing on their own unpublished records of confirmed reptile sightings. Furthermore, my appreciation goes to Ernest Robinson (Director KKWRC, Thumamah) for commenting on a draft of this note. I have also complied with all institutional animal care guidelines.

The Common Mudpuppy, *Necturus maculosus maculosus*, is a large (20–30 cm) paedomorphic salamander that is aquatic in all life stages (Conant and Collins 1998). The mudpuppy is found in lakes and streams throughout eastern North America, ranging from the Great Lakes region to eastern Oklahoma and the northern borders of Mississippi, Alabama, and Georgia (Bartlett and Bartlett 2006).

Amphibians play a critical role in food webs, transferring energy from the lowest trophic levels to the higher organisms, and from aquatic to terrestrial systems through predation (Wilbur 1997). The Common Mudpuppy is essentially nocturnal, preying mainly upon fish, fish eggs, crayfish, aquatic insects, snails, and mussels, and residing beneath structures such as logs, rocks, and weeds during the day to avoid predators (Bishop 1941; Petranka 1998). Mudpuppies are reportedly consumed by large fish, Northern Watersnakes (*Nerodia sipedon*), Snapping Turtles (*Chelydra serpentina*), aquatic birds including Double-crested Cormorants (*Phalacrocorax auritus*; Coleman 2009), and possibly River Otters (*Lutra canadensis*) and Mink (*Mustela vison*; Gibbs et al. 2007). In systems where the mudpuppy acts as predator or prey, information regarding its life history and physiology contributes to the understanding of the system's ecological processes.

Bioenergetics models have been used to address a variety of ecological and management questions (Hansen et al. 1993; Kitchell 1983). Model applications vary, but typically require physiologically-based bioenergetics equations with empirically derived parameters (Hansen et al. 1993). For models that estimate predator growth or consumption, predator size and diet are essential parameters. Diet is usually described by examination of stomach contents that identify, to the lowest taxon possible, individual prey items and ideally provides information on prey size (typically length or age). Examination of stomach contents rarely provides direct measures of prey consumption by weight due to weight reduction attributable to digestion. Model consumption and growth estimates are based on weight, so prey length or age is converted to weight using species-specific regressions.

The objective of this note is to propose a weight-length relationship for the Common Mudpuppy. Mudpuppy weight-length information is currently lacking in the literature, so data relating mudpuppy weight to length should improve estimates from models in which the mudpuppy acts as predator or prey.

Methods.—Weight-length data were recorded from mudpuppies collected from two lakes in New York State. Oneida Lake is located in central New York and is the state's largest inland lake. The lake is 20,700 ha, shallow (mean depth = 6.8 m, max depth = 16.8 m), and polymictic (Mills et al. 1978). Oneida Lake is currently considered a mesotrophic lake (Mayer et al. 2002) and is characterized as a warmwater fishery (VanDeValk and Rudstam 2001). Trout Lake, located 135 km north of Oneida Lake in St. Lawrence County, New York, is a 150-ha lake with a mean depth of 7.4 m and a maximum depth of 33.5 m (Swart and Guetti 1987). The lake provides both coldwater and warmwater fisheries and has a "sustaining of trout" classification (Swart and Guetti 1987).

Mudpuppies were collected from Oneida Lake using trapnets in April 2001 and electrofishing in October and November 2002, and from Trout Lake by electrofishing in October 2001. Mudpuppies were caught incidentally in trapnets set to collect spawning Walleyes (*Sander vitreus*) in Oneida Lake. The net design consisted of a 1.8 × 1.8 × 1.8 m crib, outside and inside wings with a combined length of 12.8 m, and a first heart with turnaround that led into a second heart with turnaround that funneled into a third heart in the crib (Kingsbury 1964). The net utilized a 45.4-m lead, and all sections were constructed of 25.4 mm-bar-mesh multifilament netting. Shoreline boat electrofishing surveys were conducted primarily to collect Walleye samples, with mudpuppies as a secondary target. Electrofishing was conducted at night using DC to produce a current of 8 A (354 V, 60 pulses/s).

Mudpuppies were anesthetized using MS-222, and total length (mm) and weight (g) recorded. After data were recorded, mudpuppies from Oneida Lake were placed in a tank with fresh lake water until they recovered, and then released. Mudpuppies from Trout Lake were euthanized and preserved after data collection. Voucher specimens are housed at the Cornell Biological Field Station, Bridgeport, New York.

Weight-length relationships were determined for all data combined and for lake- and season-specific data sets using regression analysis of the $\log_{10}$-transformed data. Linear regression of body mass versus body length is one of the most common methods of describing body condition and has been used in many vertebrate taxa (Schulte-Hostedde et al. 2005). Lake- and season-specific regressions were compared using homogeneity of slopes (Sokal and Rohlf 1969).

Results and Discussion.—Fifty-three mudpuppies were measured and weighed; 30 mudpuppies were sampled from Oneida Lake ranging in length from 215 to 356 mm and 23 mudpuppies were sampled from Trout Lake ranging in length from 133 to 279 mm. The equation describing the pooled weight-length relationship is:

$$\text{Log}_{10}(W) = \text{Log}_{10}(TL) * 3.47 - 6.43 \quad (1)$$
$$r^2 = 0.94,\ df = 52,\ p < 0.001$$

where W represents mudpuppy weight and TL represents mudpuppy total length (Fig. 1A). Sample sizes of 30 and 23 are small for describing weight-length relationships. For fish that have body forms similar to that of the Common Mudpuppy, the rule of thumb for minimum sample size for studies investigating the relationship between weight and length is 100 (Quist et al. 2009). However, adequate sample size is related to variance associated with the sample.

Because 94% of the variation in weight of the pooled mudpuppy sample was explained by length, we believe Equation 1 provides a reasonable description of the relationship between mudpuppy weight and length for the range of lengths sampled.

Equation 1 likely describes the weight-length relationship of adult mudpuppies. Bishop (1926) provided lengths-at-age of 185 mudpuppies collected from French Creek, Crawford County, Pennsylvania. None of the specimens sampled attained 130 mm until age 4, and mudpuppies at age 5 ranged from 169–210 mm. Sexual maturity is reached when individuals exceed 200 mm (Bishop 1926). All but three of the mudpuppies sampled in this study were larger than 210 mm and, therefore, were likely adults.

Species weight-length relationships can vary among seasons within a system. The equations describing the spring and the fall weight-length relationships for mudpuppies in Oneida Lake are:

$$\text{Spring: } \text{Log}_{10}(W) = \text{Log}_{10}(TL) * 2.06 - 2.92 \qquad (2)$$
$$r^2 = 0.54,\ df = 19,\ p < 0.001$$

$$\text{Fall: } \text{Log}_{10}(W) = \text{Log}_{10}(TL) * 2.85 - 4.88 \qquad (3)$$
$$r^2 = 0.94,\ df = 9,\ p < 0.001$$

For Oneida Lake, a weight-length regression comparison of spring and fall mudpuppies indicated mudpuppies caught in the spring were heavier than mudpuppies caught in the fall (homogeneity of slopes: df = 26, t = 2.55, $t_{0.05(2),\ 25} = 2.06$), and the difference in weight at a given length decreased with increasing length (Fig. 1B). A possible explanation for this difference may be attributed to differences in method of collection. Spring mudpuppies were collected from trapnets constructed of 25.4 mm-bar-mesh multifilament netting. It is possible that for smaller mudpuppies, this mesh size was not capable of retaining individuals that were leaner (weighed less) but was capable of retaining larger individuals regardless of their condition. This would result in a spring weight-length regression that would overestimate the calculated weight of smaller mudpuppies. Annual reproductive cycles may offer another possible explanation for the seasonal variability we observed. Although mating generally occurs in the fall, females store sperm and do not oviposit until May or early June (Bishop 1941; Gibbs et al. 2007). Thus, the presence of gravid females in April samples may have resulted in higher weights at a given length than if eggs were already deposited (Welsh et al. 2008). Harris (2008) found female weights at a given length varied within a population of Four-toed Salamanders (*Hemidactylium scutatum*) and attributed this variation to nesting behavior.

An alternative explanation for the differences in spring and fall weights at a given length is the effect of outliers. Visual inspection of the data suggested the smallest mudpuppy in the spring data set was heavier than would be expected. Elimination of this data point from the spring data set increased the slope of the spring regression to 2.68 and increased the r-square to 0.61. Further analysis testing the homogeneity of slopes indicated the spring and fall relationships were not statistically different for Oneida Lake mudpuppies once the outlier was removed (df = 25, t = 0.55, $t_{0.05(2),\ 25} = 2.06$). The resulting weight-length relationship of the pooled Oneida Lake data is:

$$\text{Log}_{10}(W) = \text{Log}_{10}(TL) * 2.82 - 4.78 \qquad (4)$$
$$r^2 = 0.84,\ df = 28,\ p < 0.001$$

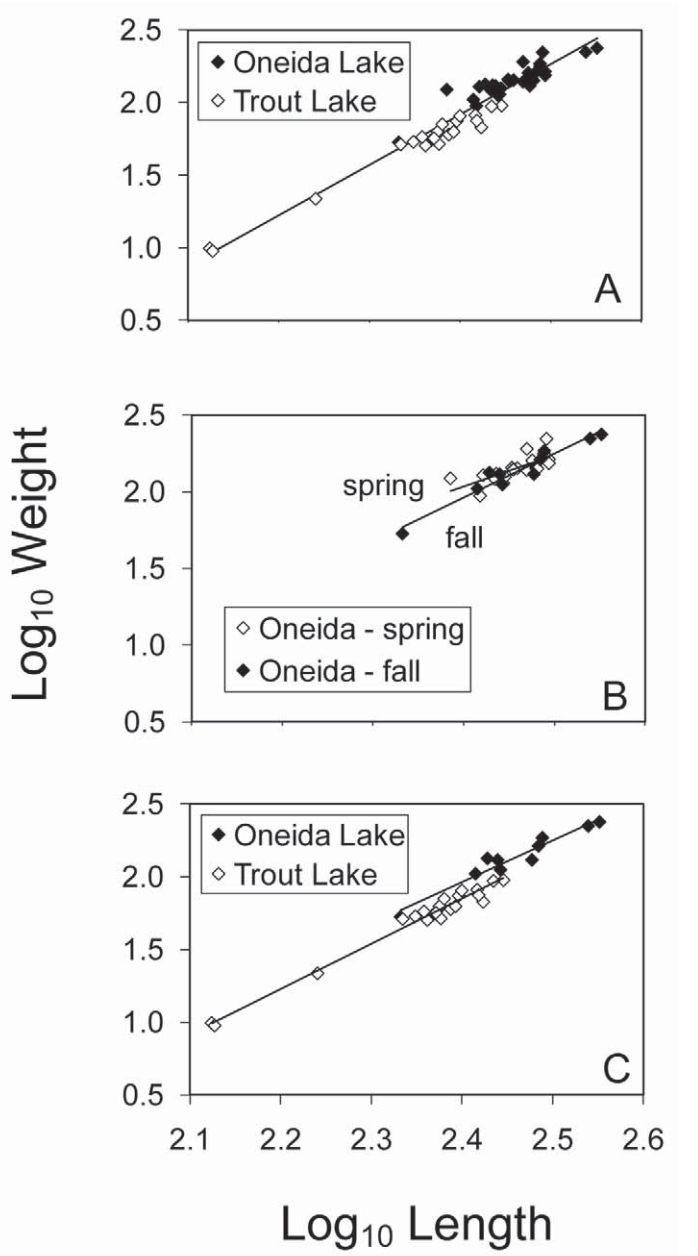

FIG. 1. Weight versus length data ($\log_{10}$ transformed) for the Common Mudpuppy (*Necturus maculosus maculosus*) from A) Oneida and Trout lakes, pooled; B) spring and fall from Oneida Lake; and C) Oneida and Trout lakes, fall only.

Empirical data are inherently variable and removal of individual data from data sets needs to be justified. While we cannot identify any reasons, other than nonconformity (possibly due to recording error), to eliminate the smallest mudpuppy from the spring data set, Equation 4 likely provides the most appropriate description of the weight-length relationship for the Common Mudpuppy in Oneida Lake.

Slopes from the weight-length relationships for mudpuppies from Oneida Lake were less than 3.0, suggesting a compressed body form. Mudpuppies sampled from Oneida Lake were observed to have a somewhat flattened body form that was most obvious for larger individuals. This observation is consistent with other published descriptions. Bishop (1941) described mudpuppy body

form as "The body is stout, depressed, and with a distinct median dorsal groove." Gibbs et al. (2007) describes mudpuppies as having "flat heads" and a "laterally compressed tail."

Species weight-length relationships can vary among systems. The equation describing the Trout Lake weight-length relationship for mudpuppies caught in the fall is:

$$\text{Log}_{10}(W) = \text{Log}_{10}(TL) * 3.10 - 5.60 \quad (5)$$
$$r^2 = 0.98,\ df = 22,\ p < 0.001$$

Lake-specific regression comparison indicated mudpuppies caught in the fall from Trout Lake and Oneida Lake increased in weight with length at a similar rate ($df = 29$, $t = 0.73$, $t_{0.05(2),\ 29} = 2.05$), but that mudpuppies from Oneida Lake were heavier at any given length within the observed length range (Fig. 1C). An explanation for this difference in weight at a given length may be related to differences in lake water temperatures. Salamander growth during the larval (aquatic) stage has been related to temperature, with higher temperatures resulting in increased growth rates (Keen et al. 1984). Similar effects of temperature have been shown for fish (Fry 1971). While no temperature data are available for Trout Lake, the existence of a sustaining coldwater fishery is indicative of a cooler environment than Oneida Lake which supports a warmwater fishery. Regardless, differences in size ranges of mudpuppies captured in Oneida Lake and in Trout Lake limit the conclusiveness of regression comparisons between the two systems.

This study presents the only Common Mudpuppy weight-length information that we are aware of. Because this study provides evidence of differences in weight at a given length between systems, system-specific relationships are desirable for investigative studies. However, in the absence of system-specific relationships, we believe the relationships presented in this paper can be useful for investigations that require information on mudpuppy weight and length. Lake-specific regressions presented in this paper can be used to represent weight-length relationships for mudpuppy populations in lakes with similar characteristics, and the pooled relationship (Equation 1) can serve as a representation for populations in other water bodies. Clearly, collection of mudpuppy weight and length data from other systems will enhance our understanding of this important relationship.

Acknowledgments.—Data collection was supported by the New York State Department of Environmental Conservation through the New York Federal Aid in Sport Fish Restoration Project F-56-R to the Cornell Warmwater Fisheries Unit. Specimen collection was authorized through New York State Fish and Wildlife License Numbers LCP01-553 and LCP02-581 and followed Cornell University Institutional Animal Care and Use Committee protocols. The authors would like to thank the staff at the Oneida Fish Cultural Station for providing mudpuppies collected in the spring from Oneida Lake, and Tom Brooking for providing mudpuppies from Trout Lake. The authors would also like to thank M. Mahoney, T. Pauley, and one anonymous reviewer for their critical and constructive reviews of the manuscript. This is contribution #267 from the Cornell Biological Field Station.

Newly hatched crocodilians have a structure called a "cliteropenis" (CTP), which generally is similar in morphology between sexes (Raynaud and Pieau 1985). Neonates of *Caiman crocodilus* and several species of *Crocodylus* display discernable differences between the penis and clitoris (Hutton 1987; Lang et al. 1989; Lang and Andrews 1994; Ziegler and Olbort 2007). The cliteropenis has an asymmetrical structure with a rounded sector (head), supported from the base by an elongated structure (neck). The head has a cleft on the top, in which the tip rests when in a relaxed position, but from which it protrudes when it is erect (Kelly 2002).

The development of the sexual phenotype in crocodilians is also interesting because in all species studied the temperature at which the eggs are incubated determines the sex (Lang and Andrews 1994). Indeed, many reptiles exhibit this temperature-dependent sex determination (TSD). The TSD pattern varies among species and percentage of sexes in nest can be 100% male or 100% female according to the incubation temperature (Janzen and Paukstis 1991), making it difficult to ascertain the sex of individuals without knowing the thermal conditions they experienced during embryonic development.

The Broad-snouted Caiman (*Caiman latirostris*) is the southernmost South American crocodilian, reaching to 32.53°S in its geographic distribution (Melo 2002). This species exhibits the FMF (female – male – female) pattern of TSD (Elf 2003), where females are obtained at 30ºC and 34.5ºC and males at 33ºC (Piña et al. 2003). As in other crocodilians, sexing hatchling *C. latirostris* by cloacal examination is currently possible only when they are larger than 60 cm snout–vent length (SVL) (AL, pers. obs.). However, depending on incubation temperature, genital differentiation in hatchlings varies among species (Allsteadt and Lang 1995; Guillette et al. 1999). Previous studies have even shown differences in size and shape of the CTP in hatchling *Alligator mississippiensis* (Ziegler and Olbort 2007).

The aim of this study was to measure the genitalia of male and female *C. latirostris* at hatching to identify a method of sexing hatchlings by cloacal inspection using digital images. There is no background research on this issue for *C. latirostris*, which currently requires the sacrifice of hatchlings to ascertain sex. However, the species is a valuable natural resource in Argentina (Larriera 1998) and Brazil (Verdade 2001), where conservation and management programs have stimulated research on many aspects of its biology. We hypothesized that the CTP of hatchlings differs between males and females of *C. latirostris*. In particular, we expected to find sex-related differences in the morphometry of the CTP.

Materials and Methods.—Wild *Caiman latirostris* eggs were collected from the San Cristóbal region (30.197406°S, 61.008717°W), Santa Fe, Argentina, during the 2006 nesting season (December–January) (Larriera and Imhof 2006). Seventy-eight eggs (one week old) from three clutches (the clutches were split evenly between two temperatures) were artificially incubated at constant temperatures of 30°C or 33°C (Larriera et al. 2008) to ensure the availability of females and males, respectively (Piña et al. 2003).

At hatching, each neonate was weighed (OHAUS, CS 200, ± 0.1 g) and snout–vent length (SVL; Vernier caliper ± 0.02 mm) from the tip of snout to posterior edge of the cloaca was measured. Twenty hatchlings (10 males, 10 females) were randomly selected for examination of genital morphology. The neonates were sacrificed for removal of the CTP and examination of the gonads. Gonadal sex was identified by the shape, texture, and color of the gonads and by the presence or absence of oviducts (Guillette et al. 1995).

CTPs were removed using a scalpel and preserved in 4% formalin for two hours. Following preservation, the right and upper sides of CTPs were photographed through a stereoscopic binocular microscope (ARCANO®; 20x). A scale alongside each CTP (+ 0.001 mm) (Fig. 1) allowed calibration of the software used for measurements of digital images (Image Pro Plus Version 4.5.0.20; 1993–2001 Media Cybernetics, Inc.). The software needs to set a calibration unit for the active picture, in this case our unit was 1 mm (obtained from the digital caliper alongside the CTP).

Three dimensions were measured from digital images of preserved CTP tissue: 1) Head Width (HW), measured from the

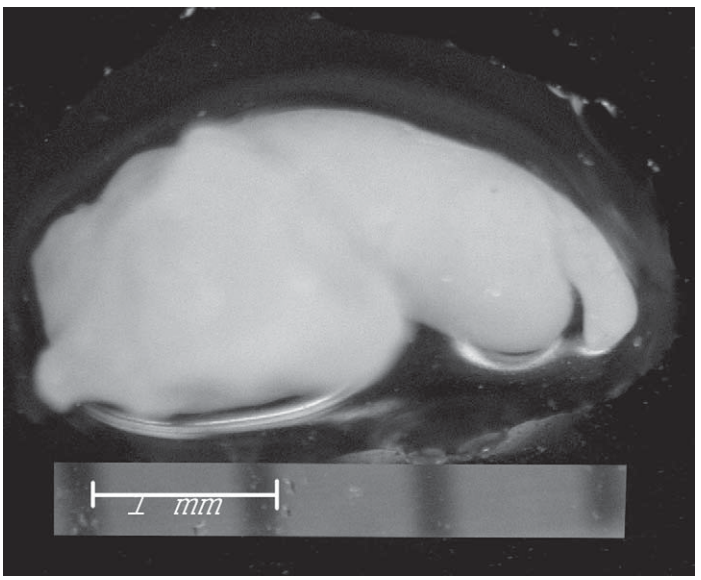

FIG. 1. Preserved CTP of hatchling *Caiman latirostris* removed from the cloaca. The scale below is from the digital caliper positioned in every picture to ensure real scale on the image in the moment of digital treatments. Scale: 1 mm

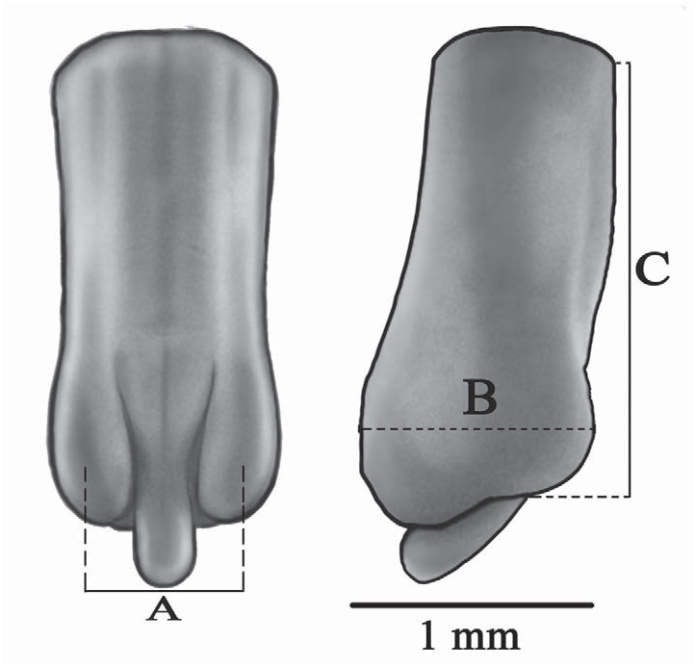

FIG. 2. Dimensions of hatchling cliteropenis *Caiman latirostris* (Left) **A** = Head Width (mm). (Right) **B** = Lateral Width (mm) and **C** = Total length (mm) of the CTP measured as the shortest distance from the base to the beginning of the tip.

upper surface (Fig. 2A); 2) Lateral Width (LW), measured as the maximum vertical width at the midsection of the head (Fig. 2B); and 3) Total Length (TL), measured from the base to the tip where it begins to separate from the head region (Fig. 2C). Also CTP volume was calculated by assuming a cylindrical structure with an ellipsoid base ($V = \pi$ [LW/2] [HW/2]TL), which slightly underestimates real volume.

InfoStat/Profesional version 1.1 was used for all statistical procedures (F.C.A 1999). All data were checked for normality and homogeneity of variances (Shapiro-Wilks and Levene test). Differences in CTP dimensions between the sexes were evaluated with t-tests (Zar 1999). A discriminant analysis with cross-validation for the variables for both sexes was subsequently run on the data set. Scatter plots were then made to create a key for future assessments of hatchling sex.

Results.—Internal sex identification: female gonads were elliptical and elongate in shape, and light beige in color with a granular texture; Müllerian ducts were clearly visible on the side of each ovary (Fig. 3). Male gonads had a similar shape, except the left testis was more elongate than the right testis (a characteristic of the sex), the color was a dark yellow, and the texture was less granular than ovaries of females; the vasa deferentia were present (Fig. 4). All females (N = 9; one of the samples was damaged in the process and we removed it from the analyses) were produced from constant incubation at 30°C and all males (N = 10) from constant 33°C incubation, consistent with the pattern of TSD in this species (Piña et al. 2003).

Cliteropenis of hatchlings: There was no significant difference in TL of the CTP between males and females ($P = 0.065$), but the CTP of males was significantly wider (t-test: LW, $P < 0.01$; HW, $P < 0.01$), and as a consequence volume was also significantly greater in males than in females ($P < 0.01$) (Table 1).

TABLE 1. Average values of variables for both sexes ± SD. (*) Significant average values ($\alpha = 0.05$) (t-test).

CTP variables	FEMALES (N = 9)	MALES (N = 10)
Lateral Width (LW*)	(1.08 ± 0.10) mm	(1.34 ± 0.07) mm
Head Width (HW*)	(0.57 ± 0.11) mm	(0.74 ± 0.13) mm
Total Length (TL)	(2.19 ± 0.48) mm	(2.73 ± 0.76) mm
Volume (*)	(1.09 ± 0.31) mm^3	(2.12 ± 0.17) mm^3

Discriminant analysis showed the presence of separate groups of males and females and the cross-validation analysis showed evidence of a strong model considering the sample size and the CTP variables (proportion hatchlings correct in classification with cross validation is 0.895 versus initial classification of 0.947). Cross-validation reduces the number of measurements, thereby reducing handling time and stress to the animals and compensates for an optimistic apparent error rate in classifications, defined as the percentage of misclassified observations (MINITAB, 2000)

A homogeneity of covariance matrix test suggested that this analysis is suitable for these data ($N = 19$; $df = 21$; $P < 0.05$), with HW the most significant variable in the group discrimination ($F = 9.03$; $df = 17$; $P < 0.01$). In cross classification results, all males

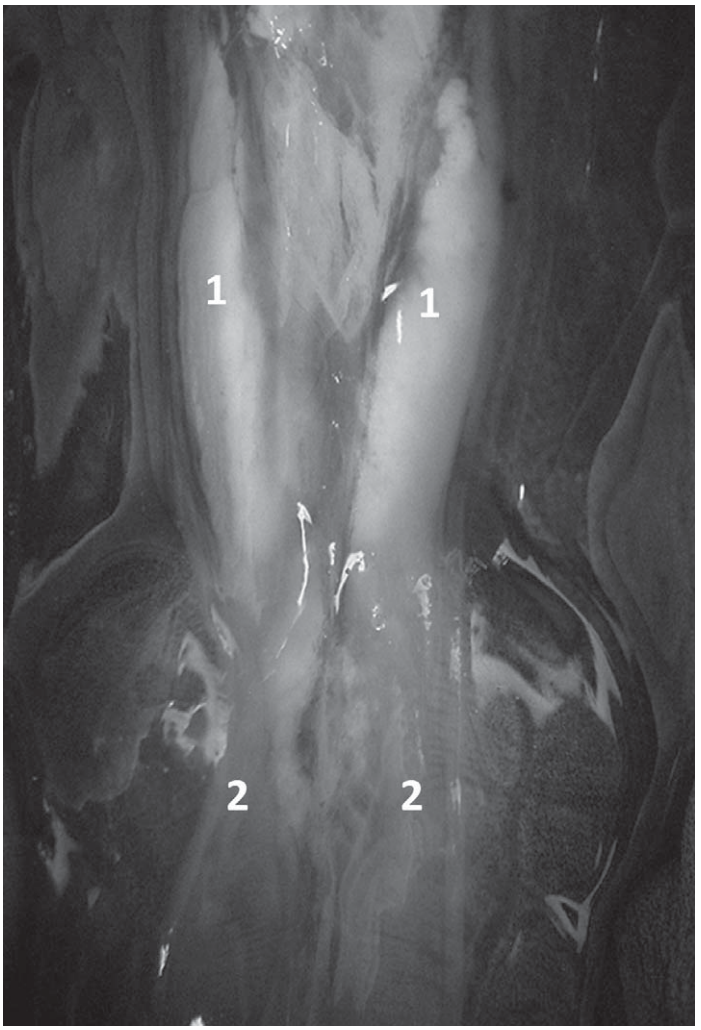

FIG. 3. Gonads of female hatchling *Caiman latirostris*. (1) ovaries, (2) Müllerian ducts.

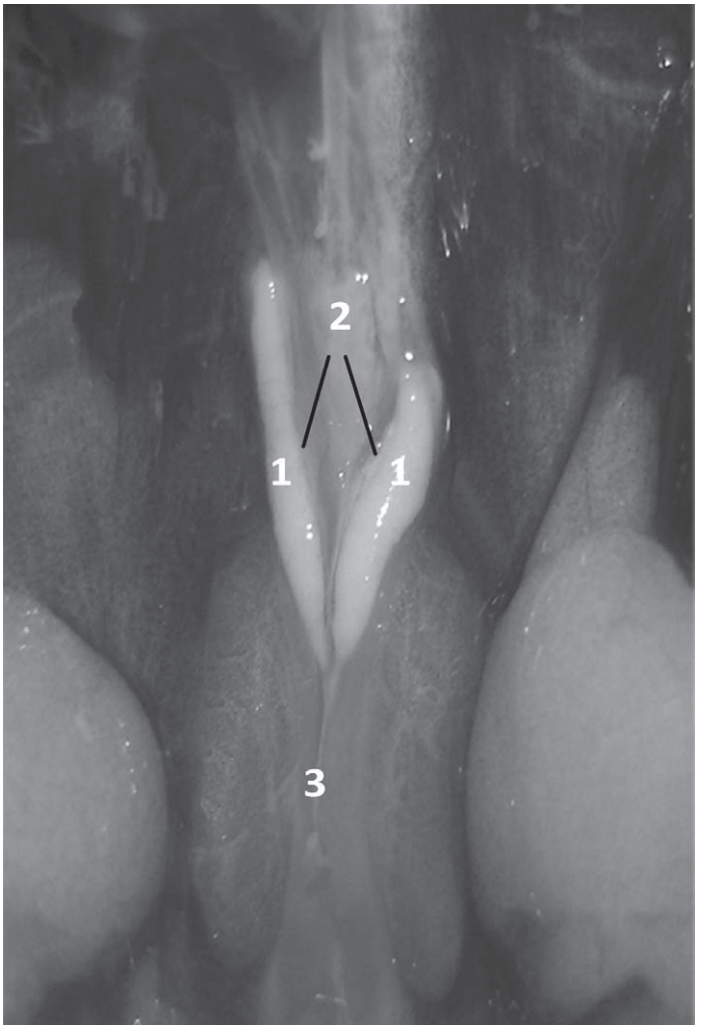

FIG. 4. Gonads of male hatchling *Caiman latirostris*. (1) testicles, (2) adrenal glands, and (3) vasa deferentia.

were classified correctly and only one female of nine was misclassified. Scatter plots of LW and HW of the CTP of hatchling *C. latirostris* revealed two groups: males formed a cluster above and to the right of the female cluster (Fig. 5).

Scatter plots of LW vs. SVL and HW vs. SVL were made to examine the distribution of these two variables in the group of hatchlings tested (Fig. 6). These results are consistent with those obtained in the discriminant analysis. We selected width limits to create a preliminary "key for sex differentiation" to classify hatchlings as males or females based on CTP measures. Of 19 samples, we sexed nine correctly as males and seven as females in the first step of the process. One more sample was classified as a male in the second step but two remained indeterminate (no. 7 and no. 9) using the key. These latter two samples were identified as females upon subsequent inspection of the gonads. Using the size limits on the graphics, we determined sex for 85% of the samples correctly, which is similar to the error rate in the discriminant analysis (i.e., 11%).

Discussion.—Previous studies found that reptiles such as *C. latirostris* exhibit TSD (Crews et al. 1994; Lance 1997; Lang and Andrews 1994; Pieau 1999). We corroborate this finding by obtaining 100% males at 33°C and 100% females at 30°C (Piña et al. 2003) as assessed by gonadal inspection (Ferguson and Joanen

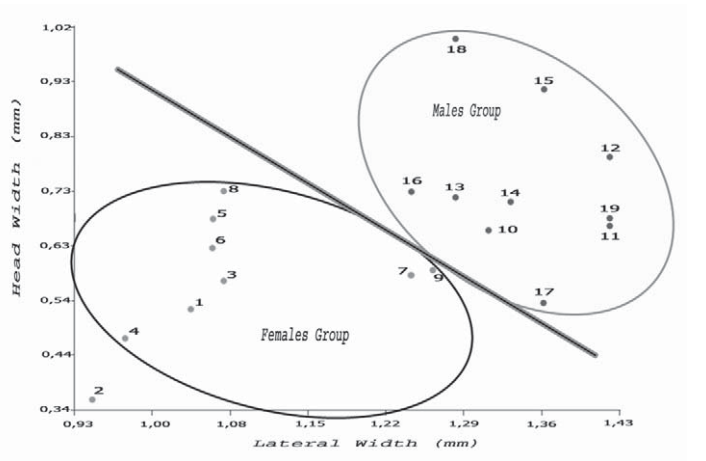

FIG. 5. Scatter plot showing the relationship between Lateral Width (mm) and Head Width (mm) of females (numbered 1–9) and males (numbered 11–19).

1983; Guillette et al. 1995).

Male CTP width and volume dimensions were significantly larger than those for females, which was somewhat surprising because the genital morphology in young crocodiles is similar. Still, prior studies found that incubation temperature affected both genital dimensions and gonadal sex determination in other crocodilians. Hatchling CTPs in *A. mississippiensis* differed in volume between the sexes and increased with increasing temperature of incubation from 30°C to 33°C (Allsteadt and Lang 1995). The CTP in hatchling *C. porosus* differed in HW and LW (Webb et al. 1984) and in size and shape in *C. niloticus* between males and

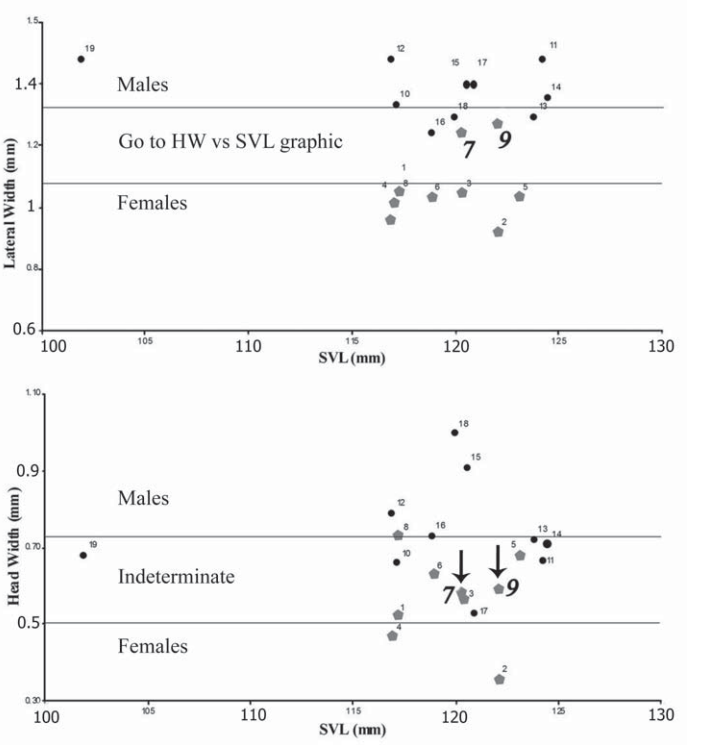

FIG. 6. Scatter plots of LW (mm) vs. SVL (mm) (*upper*) and HW (mm) vs. SVL (mm) (*lower*) values for males (black circles) and females (grey pentagons) groups. Arrows indicate hatchlings designated indeterminate by this method, but sex as females by gonadal inspection.

females (Hutton 1987).

To date the discrimination of newly hatched caiman into males and females has not been possible by observing the external genitalia. We show that such separation can be achieved from simple measures that can be recorded on the cliteropenis. The photographic measurement technique detailed herein was also tried on live hatchlings, which decreases stress on the hatchlings compared to measuring with digital calipers. This work continues in that this technique will be tried on live animals measured at hatching for which we will evaluate sex after one year of growth under controlled conditions of temperature, light, and diet.

To determine the sex in this and other species of crocodiles using a simple methodology opens the possibility of analyzing the sex ratio of offspring born in natural conditions, an unfinished agenda so far. This work is an important precedent for *C. latirostris* and similar species and lays the groundwork for a more advanced method of measurement that minimizes manipulation of individuals and measurement errors that can lead us to sex hatchlings incorrectly. Moreover, this new technique eliminates the current need to sacrifice young caimans to sex them for research work, ranching programs, and husbandry activities.

Acknowledgments.—We thank "Proyecto Yacaré" (CONVENIO MUPCN/Government of Santa Fe, Argentina) for permission to use caiman eggs collected by them. We also thank Rafael Ramos for help with 3D models of CTP. Finally, we especially thank Charlie Manolis for suggestions on this manuscript and to Fredric Janzen for English assistance and other important suggestions. We complied with all applicable institutional animal care guidelines.

Knowledge of animal body composition is important to studies of energetics, reproduction, and life history (Congdon et al. 1982; Secor and Nagy 2003), because it allows researchers to estimate body condition, parental energy investment, fitness, and productivity throughout an individual's life. Additionally, quantifying body composition is important for clinical studies of nutrition and metabolic disorders (Elowsson et al. 1998). The use of non-destructive techniques to determine body composition is essential for many studies including those involving mark-recapture and endangered species (Secor and Nagy 2003). With growing concern for the status of many species and the increased availability of technology for non-invasive procedures, destructive techniques will become increasingly unpopular.

A need for non-destructive techniques in chelonian research is becoming more apparent. Currently 80 chelonian species are listed as extinct, extinct in the wild, endangered, or critically endangered (IUCN 2007). As long-lived vertebrates with delayed sexual maturity, some turtle populations may be prone to anthropogenic harvest especially when adult survivorship is reduced (Congdon et al. 1993; Heppell et al. 1995). Therefore, the development of techniques that could reduce the permanent harvest of adult turtles for scientific purposes is important in helping reduce impacts to turtle populations. Potentially, dual-energy x-ray absorptiometry (DXA) could provide this service.

DXA was originally developed as a non-invasive tool that predicts bone density and risk of osteoporosis in humans. The physical principles of DXA technology have allowed expansion of its uses to the quantification of body composition in humans and other mammals. Recent applications to snakes and lizards have shown promise for the use of this technique in reptiles (Secor and Nagy 2003; Zotti et al. 2004). In turtles, DXA has been utilized to compare the effects of dietary treatments on bone density (Fledelius et al. 2005). To our knowledge, DXA has not been used to assess other measures of body composition, nor has the accuracy of DXA estimates been previously validated, in turtles. The morphology of chelonians may preclude accurate determination of body composition with DXA without prior validation. Prediction of body composition analysis, particularly lean tissue and fat mass, may be complicated in chelonians by the bony encasement of the internal organs. The estimation of lean tissue and fat mass is complicated when a large proportion of the scanning area contains bone (Jebb 1997). Moreover, turtles have a higher proportion of bone relative to body mass than most other animal species (Iverson 1984) which, along with their unique morphology, makes them of great interest for bone density research. The development of techniques to assess bone density in turtles is not only relevant to taxon-specific research, but could have broader applications in nutrition, ecology, and physiology, as well as practical applications in veterinary research and practice.

In the present study, we examined the precision and effectiveness of DXA in predicting bone density and body composition of turtles. Our aim was to develop predictive models that can be used to assess body composition from DXA measurements. These models would then be available for researchers to monitor body composition of turtles in settings where destructive techniques are not feasible (e.g. clinical practice, mark-recapture studies). We collected DXA estimates of body composition on 25 male *Trachemys scripta* and then compared these values to estimates determined later by chemical analysis of dried carcasses. Secondarily, this study compared the effects of three different techniques of immobilization (anesthesia, cooling, and euthanasia) on DXA body composition estimates because the accuracy of DXA results are known to be influenced by the movement of test subjects during scanning (Engelke et al. 1995).

Materials and Methods

Animal Housing & Use.—We obtained an in-house transfer of 25 male *Trachemys scripta* from a previous study conducted at Oklahoma State University (Ligon, Gregory, Kazmaier, and Lovern, unpubl. study). Subjects were originally wild-caught from two populations in Eastern Oklahoma and Southern Texas. *Trachemys scripta* were chosen for this study because of their accessibility, wide distribution, abundance, and well studied life-history. Subjects ranged in straight carapace length (SCL) from 123.9 to 222.8 mm (mean ± 1 SD = 159.3 ± 25.7 mm), in greatest width from 102.9 to 168.0 mm (127.4 ± 16.0 mm), and in mass from 260 to 1525 g (610 ± 281 g). Turtles were housed individually in plastic storage containers partially filled with water and were fasted for one week prior to DXA scanning to ensure evacuation of gut contents.

DXA Estimation of Body Composition.—To determine the effects of anesthesia, euthanasia, and cooling on DXA estimates, each individual was scanned using all three immobilization techniques. Scanning was performed on a Hologic® QDR-4500A fan-beam scanner equipped with a small-animal software program. Prior to scanning, the densitometer was quality-checked daily using Hologic® calibration models (anthropomorphic spine phantom and small-step phantom). Calibration procedures followed those provided by the manufacturer. Body mass was determined for all individuals prior to scanning. Each individual was scanned four times per day for three consecutive days. During scanning, indi-

viduals were positioned with the plastron inferior (dorsoventral projection). The cranial end of the individuals was facing towards, and 1 cm behind, the laser-alignment crosshair. The individual's midline was position directly in the middle of the scanning area. Each day, turtles were scanned twice without movement, repositioned, and then scanned twice more without movement. During the first two days of scanning, individuals were randomly placed in either the "anesthetized" or "cooled" condition. Anesthetized individuals received a 0.1 mg/kg medetomidine-5.0 mg/kg ketamine combination (administered IM) for immobilization during scanning followed by 0.5 mg/kg atipamezole (IM) for recovery (Greer et al. 2001). Cooled individuals were placed in a 4°C incubator for a minimum of 5 h prior to scanning and transported on ice. Individuals that were anesthetized on the first day were cooled on the second day and vice versa. On the third day of scanning, all turtles were euthanized with an overdose of sodium pentobarbital (60–100 mg/kg IP) and scanning was repeated as above. Following the three scanning days, individuals were frozen for subsequent chemical analysis of body composition.

Non-DXA Estimation of Body Composition.—We estimated the following indices of body composition for each turtle: bone mineral content (BMC), fat mass (FM), bone-free lean tissue mass (LTM), fat-free tissue mass (FFM = LTM + BMC or BM-FM), total body water mass (WM), and body mass (BM). To achieve this, individuals were thawed, dissected to remove fat bodies for easier analysis, and then dried to constant mass at 60°C. Body mass was measured after drying (BM_{dry}) to a constant mass and then used to estimate water mass (WM) by subtracting it from wet body mass (BM_{wet}) determined prior to scanning. Carcasses (fat bodies excluded) were then ground and homogenized in a Wiley mill to be used for the determination of fat, lean tissue, and bone content. Fat mass (FM) was estimated by adding the dried mass of fat bodies to total body lipid mass. Total body lipid mass was estimated by determining the average percent lipid content of two 2-g subsamples of the ground carcass, and then multiplying by BM_{dry}. The lipid content of carcass subsamples was determined by the Folch method (Folch et al. 1957). To estimate bone mass, four 1-g subsamples of the ground carcass were ashed in a muffle furnace at 600°C for a minimum of 8 h. The mean percent mineral content of the four samples was used to estimate total body bone mass by multiplying by dried BM. Lean tissue mass was determined by subtraction.

Statistics.—We regressed body mass and straight carapace length against each body composition parameter (determined chemically) using simple least-squares regression in an attempt to develop models that could be used to predict body composition from standard morphometrics. Regression was performed on $\log_{10}$ transformed data, but is presented in original scale by back-transforming regression coefficients. To examine the precision of DXA, intraindividual coefficients of variation (CV) were calculated from two scans without movement, from two scans with movement, and from all four scans for each type of body composition. To examine the effects of immobilization technique on DXA output parameters we performed repeated-measures ANOVA for each DXA parameter. Subject was analyzed as a blocking variable. When significant differences among treatment levels were detected, Tukey multiple-comparisons were used to examine where differences existed. Prior to analysis all variables were tested and deemed significantly non-normal (Anderson-Darling Test $P<0.001$). Therefore, we $\log_{10}$ transformed all masses prior to analysis. All results involving transformed data are presented in the untransformed scale using back-transformed means and asymmetric 95% confidence limits (Sokal and Rohlf 1987).

We selected anesthesia as the preferred method of immobilization and all further validation analyses were performed using DXA data of anesthetized turtles. Anesthesia was selected as the most desirable method of immobilization because it reduced difference between DXA and chemical estimates of body composition. Mean ± 1SD differences between DXA and chemical estimates for combined FM, LTM, and BMC, were 160.0 ± 94.3, 168.8 ± 101.6, and 185.4 ± 139.8 g for anesthesia, cooling, and euthanasia, respectively. Additionally, anesthesia generally resulted in more precise measurements compared to cooling (see results).

We performed simple and multiple least-squares regression analysis to develop models predicting chemical body composition (dependent variable) from DXA estimates (independent variable). We employed a best subsets regression procedure to select the variable(s) most useful in creating the predictive models. After generating predictive models we employed a jackknife cross-validation procedure as described by Secor and Nagy (2003). All values are given as mean ± 1 SD. The level of statistical significance was set at $P < 0.05$. Statistical analyses were performed on Minitab version 13.1.

Results

Water comprised 69.46 ± 3.25% of total body mass. Body composition of wet body mass was comprised of 84.82 ± 1.85% lean tissue, 13.83 ± 1.58% ash, and 1.35 ± 1.06% fat mass. Of dried body mass, 50.29 ± 2.95, 45.48 ± 4.78, and 4.23 ± 2.84 percent, was comprised of LTM, AM, and FM, respectively. The results of the least-squares regression between morphometrics and body composition estimates, determined chemically, are presented in Table 1. All models resulted in significant non-zero slopes ($P \leq 0.002$). All models had strong relationships between morphometric and body composition variables ($r^2 \geq 96.6\%$), with the exception

Table 1. Results of least-squares regressions of water mass (WM), fat-free tissue mass (FFM), lean tissue mass (LTM), fat mass (FM), and ash mass (AM), determined chemically, against body mass (BM) and straight carapace length (SCL) in male *Trachemys scripta* (N = 25). All mass units are in grams and length in millimeters.

of models predicting fat mass which showed a poor relationship between variables ($r^2 \leq 36.1\%$).

Precision of DXA.—Mean intraindividual CV was calculated for 4 DXA parameters using all three immobilization techniques (Table 2). Mean intraindividual CV for four combined scans was greater than 53.7% for Fat Mass, but less than 2.0% and 6.6% for BMC and LTM, respectively. CV tended to be highest for cooled individuals and lowest for euthanized individuals when examining BMC, BMD, and FM; however for LTM there was less precision when examining euthanized individuals while anesthesia resulted in more precise measurements (Table 2).

Effects of immobilization technique.—Immobilization technique significantly influenced the use of DXA to determine BMC (repeated-measures ANOVA; $F_{2,48} = 12.07$; $P < 0.001$), BMD ($F_{2,48} = 25.51$; $P < 0.001$), FM ($F_{2,48} = 16.26$; $P < 0.001$), LTM ($F_{2,48} = 15.44$; $P < 0.001$), and body mass ($F_{2,48} = 4.99$; $P = 0.011$). The effect of immobilization method was not consistent among the DXA parameters analyzed (Fig. 1).

Evaluation of DXA accuracy.—DXA estimates of body composition were highly correlated with chemical estimates for bone mass ($r^2 > 0.986$) and lean tissue mass ($r^2 > 0.964$) regardless of the method used to immobilize individuals during DXA scanning (Fig. 2A, B); however DXA estimates were poorly correlated with chemical estimates for fat mass ($r^2 < 0.261$; Fig. 2C). DXA estimates were significantly different than chemical estimates for AM (paired T-test; $T = 112.95$; $P < 0.001$), LTM ($T = 7.71$; $P < 0.001$), BM ($T = 4.42$; $P < 0.001$), and FM ($T = 4.46$; $P < 0.001$). DXA underestimated BMC, but overestimated FM, LTM, and BM regardless of the immobilization method used (Fig. 3).

DISCUSSION

The goal of developing new techniques to quantify observations is to provide users with advantages not afforded by previous methodologies. The application of non-destructive techniques, although non-invasive and therefore desirable, often sacrifices accuracy and precision. The utility of any technique is dependent on its ability to produce accurate and more importantly precise measurements. Accuracy is less important because predictive regression equations can be developed to correct for any biases inherent to the technique. The use of DXA for the quantification of body composition brought great promise because it is non-invasive and has a high degree of precision compared to other in vivo techniques (Jebb 1997).

We assessed the precision and accuracy of DXA in predicting bone density and body composition of turtles. With the exception of fat mass, the precision of tissue components, as determined by DXA, was relatively high and similar to that determined for other species/studies. In our study lean tissue mass, fat mass, and bone mineral content of anesthetized turtles had CV of 1.05, 28.54, and 1.00%, respectively. In mice, CV was similar to this study for BMC (1.60%) and LTM (0.86%), but fat mass (2.20%) was predicted much more precisely than in our study (Nagy and Clair 2000). In rats, mean CV of five rats over a three day period was 1.07% (BM), 12.16% (FM), 2.88% (LTM), and 6.34% (BMC; Rose et al. 1998). DXA also provided precise measurements of BMC (CV = 0.90%) for excised humeri of rats, but other body composition variables were not examined (Kastl et al. 2002). In domestic pigs CV was 0.74%, 0.94%, 1.91%, and 13.51% for BM, LTM, BMC, and FM, respectively (Elowsson et al. 1998). Studies investigating DXA precision of non-mammalian vertebrates, although less prevalent, suggest similar degree of precision. Korine et al. (2004) measured CV of 1.28%, 1.87%, and 4.92% for BM, LTM, and FM, respectively for live specimens of two species of birds. Precision of body composition estimates for snakes were also similar to that of this study for BMC (CV = 1.0%) and LTM (CV = 0.6%; Secor and Nagy 2003). Overall, precision of body composition estimates determined in this study fall within or below ranges found in other studies. The most notable exception is fat mass which has high intraindividual variability. Although the precision of DXA fat mass estimates are discouraging, the similar degree of precision in estimating other indices of body composition in turtles is promising. The similarity of precision compared to that of other species in particular humans and rodents, for which software was originally designed, is promising for the continued application of DXA in research involving chelonians.

Influence of immobilization.—Use of DXA requires that subjects remain motionless during the entire scanning process. Subject movement during scanning significantly and unpredictably influences the accuracy and precision of body composition estimates (Cawkwell 1998; Koo et al. 1995). A goal of this study was to determine which, if any, of the immobilization techniques resulted in the most precise and accurate measurements while at the same time reducing negative consequences associated with immobilization. Negative consequences associated with immobilization include: cost, ease of use, recovery rate, and potential for harm of test subject. Ignoring precision and accuracy, cooling is the most

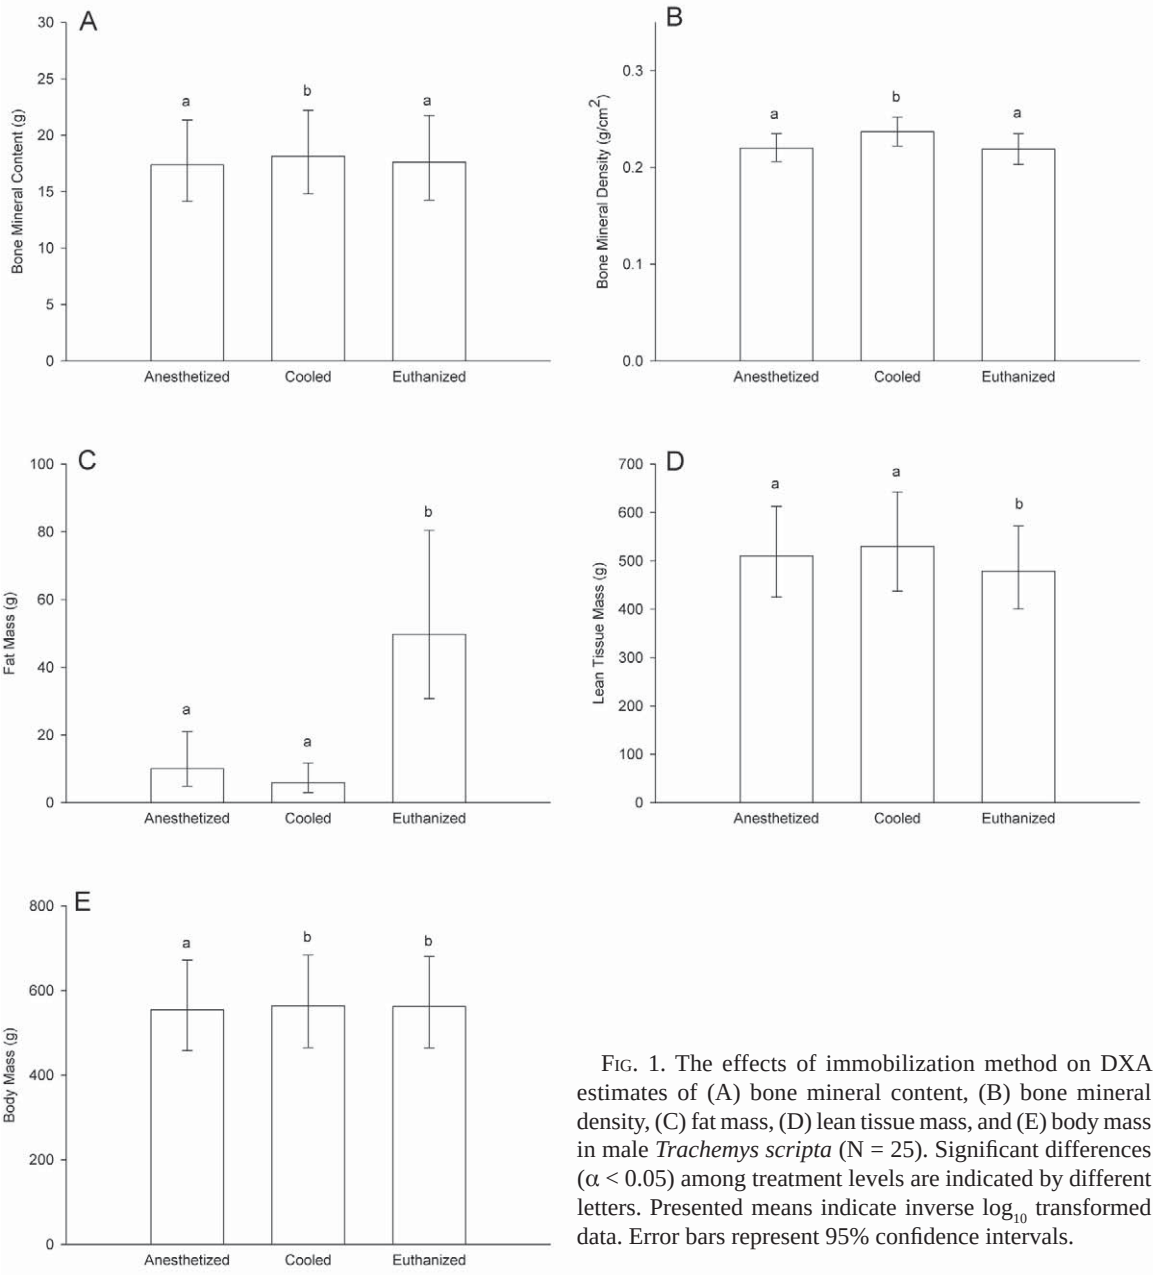

FIG. 1. The effects of immobilization method on DXA estimates of (A) bone mineral content, (B) bone mineral density, (C) fat mass, (D) lean tissue mass, and (E) body mass in male *Trachemys scripta* (N = 25). Significant differences ($\alpha < 0.05$) among treatment levels are indicated by different letters. Presented means indicate inverse $\log_{10}$ transformed data. Error bars represent 95% confidence intervals.

desirable method of immobilization, because it eliminates the cost of narcotics associated with anesthesia/euthanasia, is easy to perform, results in virtually no mortality if cooling is monitored, and has quick recovery rates. A negative consequence of using cooling is a relatively reduced effectiveness on immobilization compared to the other techniques used in this study. We found cooled individuals were more likely to move during scanning (personal observation) and could account for the lower precision of body composition estimates. Anesthesia effectively produces immobilization if a sufficient dose is given for induction; however, anesthesia can be less predictable in reptiles, occasionally producing long recovery periods, variable induction dosages, and increased mortality compared to mammalian species (Bennett 1998; Read 2004). Despite these limitations, anesthesia produces more precise and accurate estimates of body composition than cooling. Euthanasia, although required in this study for comparisons, is the least desirable method of immobilization with DXA because it necessarily defeats the purpose of using non-destructive techniques. Although the influence of immobilization technique produced significant differences in estimates and noticeable variation in precision, each technique correlated well with chemical estimates and therefore each is generally acceptable if predictive equations are produced.

Limitations of DXA.—The results of this study suggest that accurate prediction of fat mass and, to a lesser degree, lean tissue mass using DXA is questionable in chelonians. The morphology of chelonians precludes the ability to effectively determine fat mass, due to the method that DXA utilizes to estimate fat mass. Fat and bone-free lean tissue mass can be distinguished and are calculated from the ratio of attenuation from the low and high-energy beams when calculations are performed on non-bone areas; however, when calculations are performed where lean tissue, fat, and bone overlap, the calculations of fat and lean tissue components are indirect, leading to less reliable estimates (Jebb 1997). Fat and lean tissue mass estimates are less accurate when a large portion

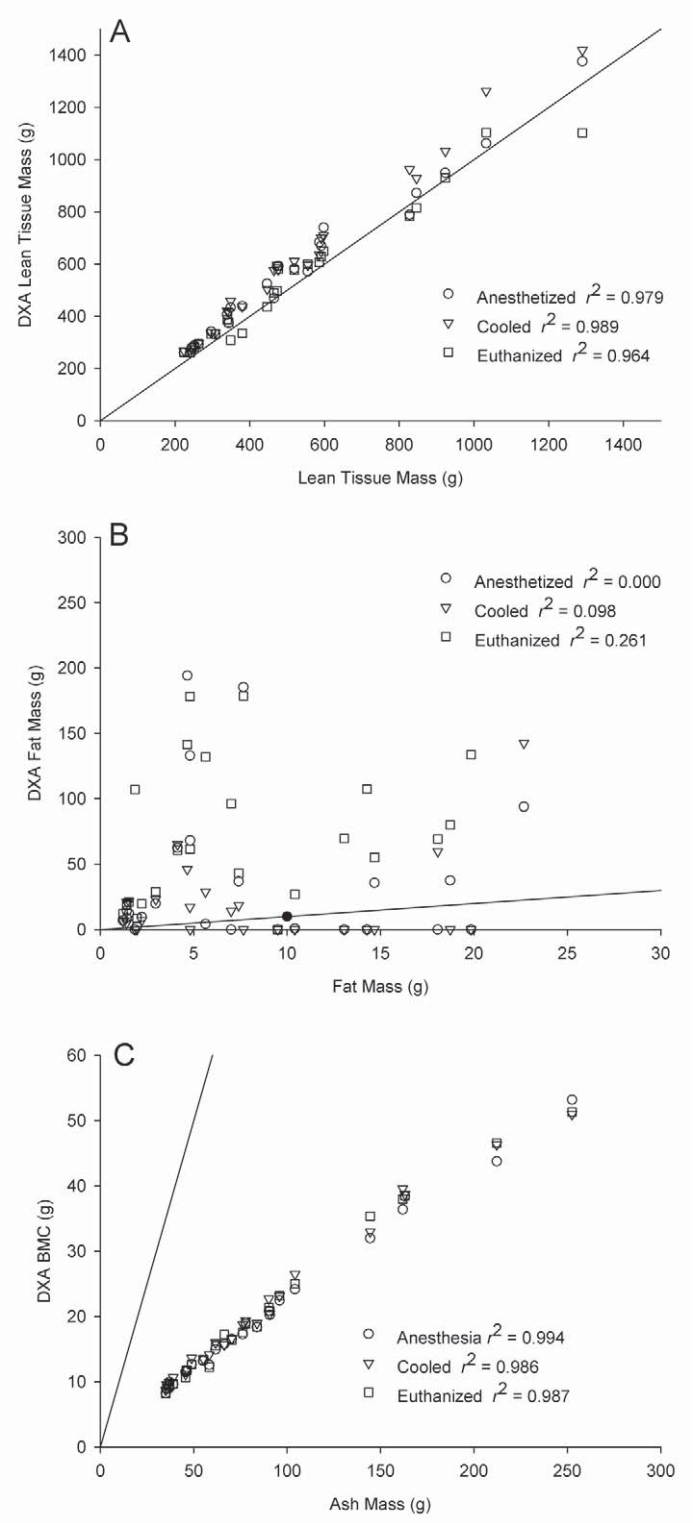

FIG. 2. Correlation between DXA and chemical estimates of (A) lean tissue mass, (B) fat mass, and (C) bone mass for all three methods of immobilization in male *Trachemys scripta* (N = 25). The solid line represents a slope of 1.

of the pixel area contains bone, such as in the thoracic region and brain in humans (Jebb 1997). The scanning of chelonians results in nearly 100% of the scanning pixels containing bone, depending on whether the appendages are extended beyond the margins of the carapace. Therefore, DXA cannot use non-bone-containing

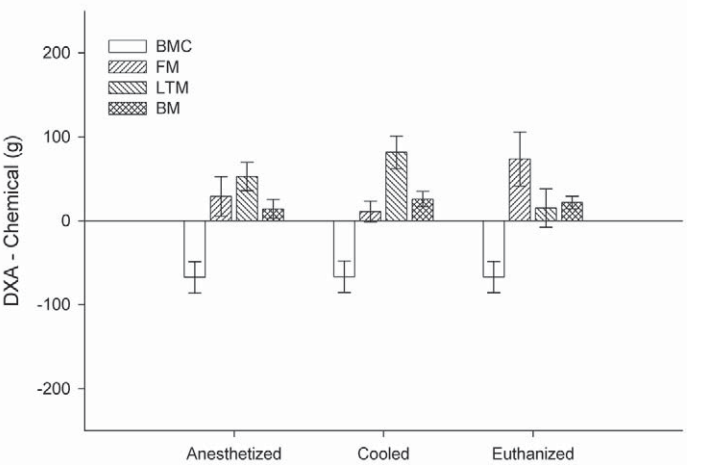

FIG. 3. Mean difference between DXA and chemical estimates of bone mineral content (BMC), fat mass (FM), lean tissue mass (LTM), and body mass (BM) for the three methods of immobilization in male *Trachemys scripta* (N = 25). Error bars represent 95% confidence intervals.

neighbor pixels to calculate the proportion of fat to be used for the majority of pixels that contain bone. Thus the unique morphology of turtles most likely prevents the use of current DXA technology to accurately estimate fat mass. Our data corroborate this view, particularly when compared to another reptile. Secor and Nagy (2003) found a relatively low CV when using DXA to measure FM in snakes (9.2% versus 28.5–97.0% in this study). Because current DXA technology precludes the use of this tool for the prediction of fat mass in turtles, chelonian research with primary interests in obtaining fat estimates will have to use other established methods. The establishment of triple or multiple-energy x-ray absorptiometry may solve this issue in turtles by using a three compartment system rather than the two compartment approach of DXA (Swanpalmer et al. 1998). Another potential approach that may help overcome this caveat could be to position the individuals such that the x-ray beams will pass craniocaudal. This approach would reduce the total scanning area that contains bone and therefore could allow for a more accurate estimate of fat and lean tissue components; however this has not been attempted and at this point is limited to speculation.

Future Research.—Future studies should examine the variation among scanners. We developed models linking body composition and DXA estimates; however the utility of these models for users of other DXA brand scanners is unknown. Significant effects of DXA manufacturers, hardware, and software have been documented (Tothill et al. 1994a; Tothill et al. 1994b; Jebb 1997; Tothill and Hannan 2000). Further validation of these predictive models on other brands of DXA scanners is needed before they can be applied to research using other brands. We also suspect that there may be interspecies variation, and separate predictive models should be developed for individual species. The use of these predictive equations, developed for *T. scripta*, with species differing drastically from the emblematic turtle morphology (e.g. soft-shelled turtles) will likely provide erroneous estimates of body composition.

In conclusion, DXA could potentially be used for a variety of evolutionary, ecological, nutritional, physiological, and diagnostic applications in animals. However, a poor ability to predict fat mass in turtles severely limits some of its application to energetic and nutrition studies until advances in technology overcome the

TABLE 3. Predictive models for chemically determined body composition variables in male *Trachemys scripta* (N = 25) determined by the regression of chemical estimates of body composition against DXA estimates for anesthetized individuals. Predictor variables were selected using best-subsets regression. The simplest model was included and multivariate models were added if they had more explanatory power. Values for difference represent the average difference between actual tissue mass determined chemically and predicted tissue mass determined from the regression or cross-validation model. Values for percent difference represent the absolute difference represented as a percentage of total mass for the tissue component in question. Abbreviations: AM = ash mass, BMC = bone mineral content, LTM = lean tissue mass, FM = fat mass, FFM = fat-free tissue mass, WM = water mass.

difficulties of distinguishing the soft tissues in species containing a high proportion of bone. Although the use of DXA in turtles is limited by soft tissue, DXA is still effective at measuring bone content and density, and therefore would prove useful for studies of bone dynamics in turtles. From an applied approach DXA could be used in the identification of metabolic bone disease in a clinical setting. The ability to monitor an individual's bone density over a lifetime could provide a wealth of information on the long-term dietary impacts on bone density. In short, the potential applications of DXA in scientific research are many; however, continued validation is required before DXA can be put into practical use for chelonian research.

Acknowledgments.—We thank Dena Hartzell and Lindsay Pascal for their assistance in the field and lab. Day Ligon provided turtles for use in this study. This study was partially supported by the Chelonian Research Foundation Linnaeus Fund, Southwestern Association of Naturalists, and Oklahoma State University Zoology Graduate Student Society. The OSU Department of Nutritional Sciences provided logistical support and access to DXA equipment. This research was approved by the OSU IACUC (permit AS0413).

One assumption, implicit or explicit, often made by researchers when designing field studies is that techniques that work well in one species will work without qualification in other species, often closely related, in which they have never been employed. This is not always true. During our ongoing work to understand the natural history and life history of Crawfish Frogs (*Lithobates areolatus*) on reclaimed surface coal mines in Indiana, we employed two techniques—internal transmitters for a radiotelemetry-based movement study and drift fences with pitfall traps for a mark-recapture demographic study—that are recommended and proven tools for amphibian field research (Dodd and Scott 1994; Gibbons and Bennett 1974; Gibbons and Semlitsch 1981; Madison 1997; Richards et al. 1994), though not without qualification (Bull 2000; Dodd 1991; Goldberg et al. 2002; Weick et al. 2005). In fact, both drift fence and radiotelemetry studies have been used successfully with closely related species, Gopher Frogs (*L. capito*; Palis 1998; Roznik and Johnson 2009) and Dusky Gopher Frogs (*L. sevosus*; Richter and Seigel 2002; Richter et al. 2001). We report here two previously undescribed difficulties with the implementation of these techniques in Crawfish Frogs.

We have discovered that surgically weakened abdominal musculature following the implantation of internal transmitters can lead to visceral herniation through the incision site in calling male Crawfish Frogs. Secondly, we have observed that upon exiting wetlands and encountering a drift fence, postbreeding Crawfish Frogs do not usually move laterally along the drift fences to then fall into buckets. Instead—perhaps because they must travel in a specific direction, often over great distances, to find a burrow (J. Heemeyer, unpubl. telemetry data)—they often remain against the fence until early in the morning when they then turn around to re-enter the wetland or surrounding vegetation. This appears to be the first time that these two issues have been reported in amphibian field studies.

Transmitter implantation can result in visceral herniation.—The advantages of radiotelemetry are well known, with the one limitation most cited being transmitter longevity, which is related to transmitter size (Richards et al. 1994; Van Nuland and Claus 1981). Smaller transmitters, often necessary for use in smaller animals such as amphibians, have smaller batteries, which have a shorter life, either making for short-term studies or adding to the number of transmitter replacements. External harnesses have been used successfully on Gopher Frogs (Richter et al. 2001; Roznik and Johnson 2009). However, because Crawfish Frogs at our study site must negotiate densely vegetated upland prairie habitat and use small burrows (made by crayfish), we felt external harnesses might interfere with mobility and decided to implant transmitters intraperitoneally.

Intraperitoneal transmitter implantation is often used in amphibians and may be the most effective way of tracking these animals for long periods (Goldberg et al. 2002; Johnson 2006; Madison 1997; Richards et al. 1994; Weick et al. 2005). However, problems can arise both during and after surgery (Goldberg et al. 2002; Weick et al. 2005). Complications among anuran species arise from response to anesthesia (Goldberg et al. 2002; Weick et al. 2005), infection (Werner 1991), tearing of sutures, lesions around sutures, and transmitter expulsion (Weick et al. 2005). Goldberg et al. (2002) note that many anuran telemetry studies fail to discuss deleterious effects of implantation surgeries.

In the present study, Crawfish Frogs (72–188 g) were captured during the spring of 2009 either on their way into breeding wetlands (drift fences) or in breeding wetlands (minnow traps). Because Crawfish Frogs will often quit calling at the least sign of disturbance (Parris and Redmer 2005), and because intraperitoneal transmitters had been considered safe in calling frogs (Goldberg et al. 2002; Lamoureux and Madison 1999), we decided to implant a subset of males (8 out of 59 Crawfish Frog males encountered entering the pond) in order to identify wetland calling sites and where animals find refuge when they are not calling. We implanted animals with Holohil Systems Ltd. (Carp, Ontario) PD-2 transmitters with internal helical antennae (average weight of 3.8 g). Implantation surgeries were initially practiced (by JLH) on Southern Leopard Frogs (*L. sphenocephalus*) under the supervision of a researcher with over 20 years experience with animal surgeries (MJL). Richards et al. (1994) recommend the use of transmitters weighing no more than 10% of body weight; Goldberg et al. (2002) recommend no more than 5%. Our transmitters accounted for 2–5% of total body weight.

Knowing the potential negative effects of anesthesia on anurans (Goldberg et al. 2002), we started with a concentration of 200 mg/L MS-222 (ethyl 3-aminobenzoate methanesulfonic acid salt;

Sigma-Aldrich, St. Louis, MO) dissolved in a buffer solution (500 ml phosphate buffered saline [PBS], pH 7.2, giving the anesthetic solution a pH of 6.8) at room temperature. We observed the animal for 20–30 min and if it was still responsive we added 200 mg/L MS-222. This continued every half hour until the animal became fully anesthetized, indicated by loss of righting reflex and lack of pain response to toe pinching (Johnson 2006). After several surgeries, we were able determine that a concentration of 600 mg/L was optimal. At this concentration, animals usually took 20–30 min to become anesthetized and remained anesthetized through the duration of the surgery (~30 min). Transmitters were placed intraperitoneally by making a left side, off-midline abdominal incision through the skin and a parallel incision through the rectus abdominus (Johnson 2006). After transmitter insertion, the rectus abdominus was closed with five or six continuous (Weick et al. 2005) sutures (Vicryl™ [polyglactin 910] 5-0 RB1, #36; Ethicon, Somerville, NJ), and the skin was closed with five or six continuous sutures (Vicryl™) and glued (Vetbond™ [n-butyl cyanoacrylate] adhesive). Postoperatively, animals were placed in deionized water and observed until they awoke. They were allowed to recover overnight in a cold, dark environment (a cooler placed in a refrigerator) to minimize stress, and then released on the inside (opposite side) of the drift fence, or near the minnow trap, where they were captured.

Postoperatively, we periodically examined animals in the field. At various times following surgeries (5–27 days), we observed asymmetrical ventral swellings in five animals. Swellings were caused by a hard mass of tissue (Figs. 1A, B), not by fluid or air accumulation. We collected these animals, anesthetized them, did exploratory surgery, and found visceral herniations through the rectus abdominus at the point of surgical incision. The liver had herniated in all animals; the left lung, stomach, and/or intestine herniated in a subset of animals. To repair these herniations, the viscera were carefully re-inserted into the peritoneal cavity, the incised edges of the rectus abdominus were trimmed (ensuring blood flow and enabling healing in case the wound was dehisced), the muscle and skin were individually sutured closed as before, and Vetbond™ was applied to the skin. The animals were again kept overnight before they were released at their respective capture locations.

All five animals exhibiting herniations were males entering or trapped in breeding wetlands. The three other males implanted at the same time did not show signs of herniation. Herniations were not, and have not been at any time, seen in females (four females were implanted at the time and eight more females have been subsequently implanted). We (JLH and MJL) observed one of the implanted males calling (distended vocal sacs) and in amplexus prior to discovering its hernia. The breeding call of male Crawfish Frogs has enormous energy, generating sound capable of carrying over a kilometer under favorable acoustic conditions (Busby and Brecheisen 1997; Minton 2001). We suspect the abdominal pressure necessary to generate these calls (Wells 2007) caused the viscera to herniate through the healing incision and the sutures in the muscular wall.

Four of the five reconstructive surgeries were successful. A herniation in one animal was initially misdiagnosed as internal swelling underneath the muscle layer (necropsy showed liver herniation); this animal died the next day. Of the four surviving animals, the transmitter in one was removed during surgery. This frog was returned to its wetland and was captured three days later at the drift fence as it was leaving; it was behaving normally. The three remaining animals were released postoperatively at the point of capture; one died two and a half weeks later from unknown causes. At the time of this writing (~150 days post surgery), the two remaining herniated frogs with transmitters had been tracked since their release and are behaving similarly to implanted animals that did not suffer visceral herniations. One of the two animals was examined 12 days (Fig. 2A) and 40 days (Fig. 2B) after hernia reconstruction and showed no signs of recurrent herniation. Its cutaneous incision had completely healed, although portions of suture material and Vetbond™ remained adherent. These have since dissolved or been worn away.

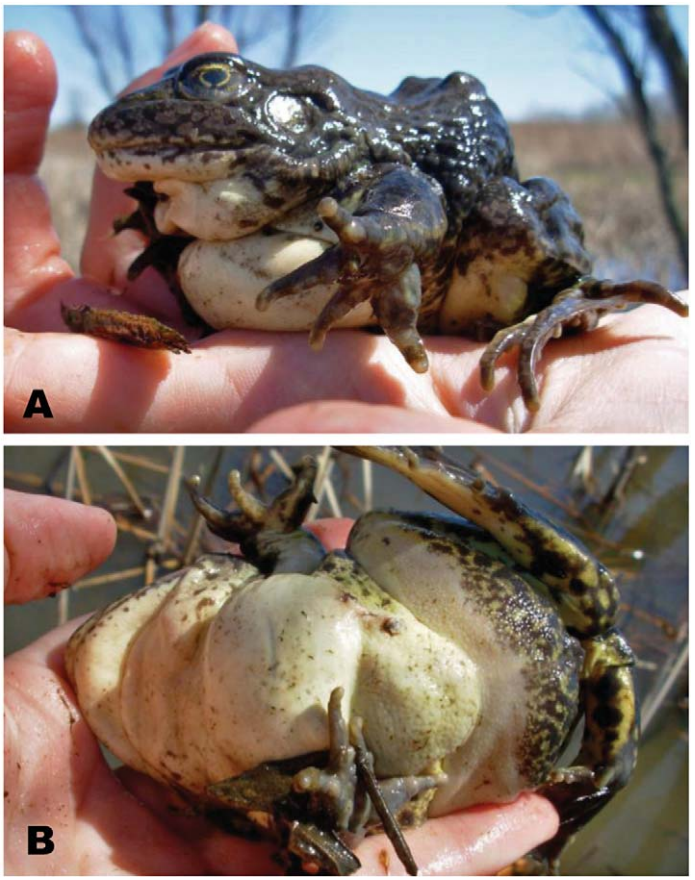

FIG. 1. A) Left lateral oblique view of a male Crawfish Frog (93 mm SVL) showing external appearance of visceral herniation through the rectus abdominus. B) Ventral view of same animal. The more anterior bulge is due to liver herniation and the posterior bulge is due to intestinal herniation.

Drift fences inhibit postbreeding migrations.—Drift fences in combination with pitfall traps constitute a useful tool for amphibian biologists interested in the timing and demographics of breeding populations, as well as measures of reproductive success (Dodd and Scott 1994; Gibbons and Bennett 1974; Richter and Seigel 2002; Semlitsch et al. 1995). One assumption with this technique is that upon encountering a drift fence, an animal will turn left or right to move laterally along the fencing until they tumble into a pitfall trap to be captured and processed by the researcher. Crawfish Frogs entering breeding wetlands seemed to do this, but Crawfish Frogs

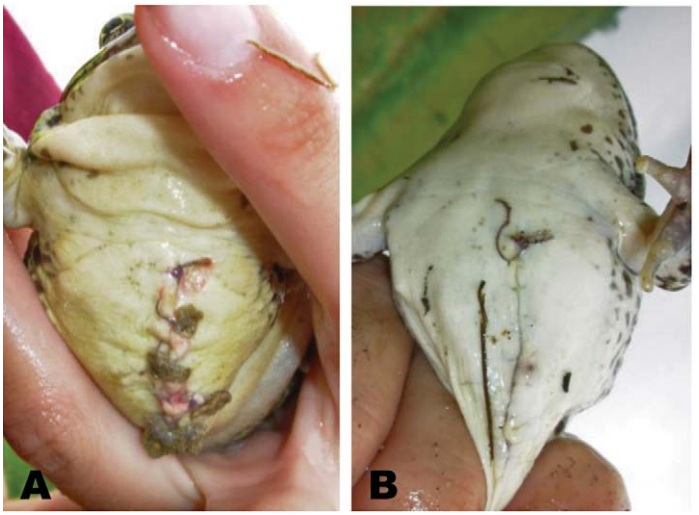

FIG. 2. Ventral view of a male Crawfish Frog (85 mm SVL) showing healing following hernia repair surgery on 16 April 2009. A) The scar on 28 April, 12 days following surgery. B) The scar on 26 May, 40 days after surgery.

exiting wetlands often did not. Difficulties with capturing animals in pitfall traps had not been specifically reported in studies that involved the closely related Gopher Frogs (Palis 1998) and Dark Gopher Frogs (Richter et al. 2001; Richter and Seigel 2002).

On the night of 12–13 April (11°C with 2.0 cm of rainfall), several postbreeding frogs were observed on the inside of the silt drift fence after having left their breeding wetland. Despite this potential emigration activity, on the morning of 13 April, no Crawfish Frogs were found in pitfall traps at this wetland. We suspected escapes, but had had no evidence that frogs trespassed entering this wetland and so doubted Crawfish Frogs could negotiate fences upon leaving. After noting emigration behavior, but an absence of frogs in pitfall traps, we began returning to our study ponds during nighttime rains. We found that when emigrating animals encountered the silt drift fence they often tried to work their way through the fence to continue their direction, sometimes laboring until, if at the aluminum hardware cloth portion of our fences, they abraded their snouts (Fig. 3). The hardware cloth—installed in drainage areas to prevent washing out of the silt fences—comprises two sections at one pond (2.86 m, 1.14% of the whole fence) and four sections at the second pond (4.87 m, 1.87% of the whole fence). The silt fence itself, made from woven polypropylene composite, did not injure frog snouts. After realizing this, we began to relocate emigrating Crawfish Frogs across fences. One night alone (19–20 April) we transferred a total of 40 (23 at one wetland, 17 at a second) postbreeding Crawfish Frogs to the outside of fences (a total of 97 animals entered our two drift-fenced breeding wetlands). Overall, 35% of emigrating Crawfish Frogs were relocated in this way, the other 65% were caught in pitfall traps. The use of drift fences may lengthen the duration of Crawfish Frogs in breeding wetlands, and therefore bias results.

FIG. 3. Head-on view of Crawfish Frog (103 mm SVL) whose snout was abraded during attempts to negotiate a direct route through drift fencing.

Recommendations.—The advantages of telemetry and drift fence trapping techniques will typically outweigh disadvantages if certain precautions are heeded (e.g., Gibbons and Bennett 1974). Several measures can be taken to adapt the telemetry and drift fence modifications described here to Crawfish Frogs, which in turn could also be useful for research on other species. In our opinion, implantation of transmitters remains a viable method for Crawfish Frogs, however, we suggest only implanting postbreeding animals to avoid the possibility of visceral herniation. We also recommend using interrupted sutures (Weick et al. 2005), which may provide stronger closure, to close the peritoneal incision. We have wondered whether the notoriously unstable, acidic, nutrient poor, and droughty soils of mine spoils (Brothers 1990) stressed Crawfish Frogs to the point of hindering healing and producing these herniations. At the present time we have no data to support this idea.

Drift fence studies for Crawfish Frogs must be accompanied by all-night visual encounter surveys for emigrating adults during or following rainfall. Animals at, or approaching, fences should be captured and relocated to the opposite side. To prevent abrasion, we recommend using softer perforated fencing in areas where water accumulates, or attaching strips of cloth or Gorilla Tape© (Gorilla Glue Inc., Cincinnati, Ohio) across the bottom of the hardware cloth. A height of two inches would provide ample protection for Crawfish Frogs, and still allow water flow through the fence.

When utilizing field techniques, even well-established techniques, we recommend not assuming that techniques that have worked well on other species will work well on novel species. We suggest incorporating either a period of preliminary analysis or an intense initial observational component to prevent unintended animal injury.

Acknowledgments.—We thank John Crawford for the early consultation on study design; Zach Terrell, Alex Robinson, John Crawford, Bill Peterman, Susie Lannoo, Pete Lannoo, and Jessica Creeden for assistance in constructing and checking the drift fences. We thank M. J. Mahoney, W. B. Blihovde, and two anonymous reviewers for comments on an earlier draft of this manuscript. This research was conducted under IACUC number 3-24-2008 issued by Indiana State University, and Scientific Purposes License Permit number 09-0084 issued by the Indiana Department of Natural Resources. This project was funded by a U.S. Fish and Wildlife

Service State Wildlife Grant, contract number E2-08-WDS13. Special thanks to Katie Smith and Ron Ronk, Indiana Department of Natural Resources, for enabling this project.

AMPHIBIAN DISEASES

This section offers a timely outlet for streamlined presentation of research exploring the geographic distribution, host range, and impact of emerging amphibian pathogens, especially the amphibian chytrid fungus *Batrachochytrium dendrobatidis* (*Bd*) and ranaviruses. *Bd* is an emerging pathogen linked to mass mortality and declines of amphibians worldwide, yet Bd has also been detected in amphibians without disease. Ranaviruses also cause mass mortality, but have not yet been linked to large-scale declines. We know relatively little about their global distribution, host range, or impacts on host populations. To improve our understanding of the scope of this issue, we encourage submission of studies that illuminate the geographic distribution, host ranges, and impact of these pathogens on amphibian populations, including research on individual species or groups of species, wild or captive animals, native or non-native species, live animals or museum specimens, environmental samples, and, provided there is sufficient sampling[1], reports of non-detections.

We ask authors to: 1) restrict the Introduction of their paper to a **maximum** of two paragraphs to highlight the context of their study; 2) briefly include both field and laboratory Methods; 3) present Results in a Table, although a map might also be useful, and limited text; and 4) have a short discussion of a **maximum** of three paragraphs to touch upon key findings. Please include the following information in submissions as appropriate: coordinates and description of sampling areas (or please note if locations are extremely sensitive to reveal, and provide general area instead); species name(s) and life history stages examined, as well as other species present; whether samples were collected randomly or just from dead or moribund animals; date of specimen collection; evidence of unusual mortality; numbers of positive and negative samples; disposition of voucher specimens; name of collaborative laboratory or researcher conducting histological sections or PCR analyses; and names of cooperative land owners or land management agencies. We encourage researchers to conduct post-mortem examinations when possible to identify the cause of death when reporting mortalities. We aim to expedite the review and publication process! Please e-mail submissions directly to Associate Editor, Dr. Dede Olson: dedeolson@fs.fed.us.

[1]If a sample of 30 individuals of a particular life history stage of a particular species yields no positive results, and the diagnostic test is highly sensitive, one can conclude that the prevalence of infection is less than 10% with 95% confidence. With a sample of 10 an infection in one of four individuals could go undetected. We encourage researchers to collect sufficient samples that negative results are meaningful.

Batrachochytrium dendrobatidis (Bd) has devastated many amphibian populations, especially in tropical areas (Berger et al. 1998; Daszak et al. 1999). However, the geographic distribution of

this emerging pathogen is not well known (see http://www.spatialepidemiology.net/Bd-maps/information/#PD). There is currently only one published report of *Bd* in Alabama, USA, at Horseshoe Bend National Park located in Tallapoosa Co. (Byrne et al. 2008); the affected species was the semi-terrestrial *Eurycea cirrigera* (Southern Two-lined Salamander). Rothermel et al. (2008) found *Bd* across the southeastern United States, but Alabama was not sampled. However, they found *Bd*-infected *Notophthalmus viridescens* (Eastern Newt) in Georgia, North Carolina, and Virginia. Additional reports have detected *Bd* in anurans and caudates in eastern Georgia (Timpe et al. 2008) and southwestern Tennessee (Venesky and Brem 2008). We report on a haphazard collection of dead adult *Notophthalmus viridescens* discovered during a field zoology class trip conducted by KAB in Birmingham, Alabama.

Methods.—On 25 February 2009, seine and dipnet sampling were conducted at Red Lakes, Ruffner Mountain Nature Preserve, Birmingham, Alabama (33.5623ºN, 86.6900ºW). Many (30–40) live adult Eastern Newts in breeding condition (smooth skin; males with nuptial pads) were sampled. We also noticed a number of recently deceased newts. The dead animals were slightly bloated, presumably due to dying in the water, were floating just above the bottom of the shallow pond (ankle to thigh deep, 15–90 cm), but otherwise appeared normal (no loose or peeling skin, no discoloration, no signs of trauma). Twelve dead newts were collected, and we saw at least another 15 dead newts. Nine newts were fixed in formalin, then stored in 70% ethanol. Three newts were preserved by freezing at -10ºC. *Ambystoma maculatum* (Spotted Salamander) egg masses were present in the pond where the dead newts were collected and two large adult Spotted Salamanders (appeared healthy) were found in the woods approximately 40 m away from the pond and released after examination. Presumably, this pond also is used by anurans as a breeding site because it is fishless and periodically dries due to evaporation when there is a hot, dry summer.

Two formalin-fixed newts were examined by APP. The fixed carcasses were demineralized in hydrochloric acid (RDO Rapid Decalcifier, Apex Engineering Corporation, Aurora, IL USA), followed by preparation of serial transverse histological sections through the entirety of head and body and longitudinal sections through the hindlimbs and feet. Body, limb and foot slices were then automatically processed for histology, embedded in paraffin, sectioned at 5-6 μm and stained with hematoxylin and eosin. Liver from 2 frozen newts was submitted to the Amphibian Disease Laboratory at the San Diego Zoo for real-time PCR for ranaviruses using previously described techniques (Pallister et al. 2007).

Results.—Lesions in the two formalin-fixed newts examined histologically were limited to the skin. Changes were diffuse and involved over 90% of the skin surfaces examined (which included multiple sections of dorsal and ventral skin from the head, torso, legs, feet, and tail) and consisted of mild to moderate orthokeratotic hyperkeratosis and epidermal hyperplasia with moderate numbers of fungal organisms in cells of the stratum corneum (superficial keratinized skin layers) typical of *Batrachochytrium dendrobatidis*. Features of these organisms considered to be diagnostic of *Bd* included colonial thalli and flask-shaped zoosporangia with prominent discharge papillae (Longcore et al. 1999). Skin lesions were significantly more severe than the relatively focal and minimal lesions observed in *Bd* infected, but healthy American bullfrogs (Hanselmann et al. 2004) and were similar to those associated with mortality in naturally and experimentally infected anurans (Nichols et al. 2001). Lesions were also subjectively more severe than those previously observed by one of the authors (APP) in other salamander species (Davidson et al. 2003; Vasquez et al. 2009). Other tissues examined histologically, including but not limited to, brain, liver (including subcapsular hematopoietic tissue), kidney, spleen, gastrointestinal tract, bone and skeletal muscle were considered to be within normal limits. Specifically, no lesions typical of a lethal *Ranavirus* infection (Green et al. 2002) or of the *Ichthyophonus*-like infections previously reported in *Notopthalmus viridescens* (Raffel et al. 2006) were observed. The examined newts were determined to be in good nutritional condition based on abundant coelomic cavitary fat stores. Real-time PCR for ranaviruses was negative. Based on these findings, chytridiomycosis was determined to be the likely cause of death. However, the small number of newts sampled for diagnostic investigation means that other potential causes for this mortality event, including but not limited to, other unidentified infectious agents and events such as chemical exposure or altered water quality. Chemical and environmental changes especially may not result in distinctive lesions that can be identified by histologic examination.

Discussion.—This report is significant in documenting the presence of *Bd* in another salamander species 110 km from the nearest known locality, Tallapoosa Co. Alabama. This is the first report of a mortality event associated with *Bd* in Alabama. Ruffner Mountain is currently used as a nature education center and is also the second largest urban nature preserve in the United States (S. McCracken, pers. comm.). However, iron ore mining was conducted here from 1886–1953 and it served as a limestone quarry through the 1920s (White 1981). Red Lakes (there were once six, now two remain) where the infected newts were found, was originally a settling pond for the water used in a beneficiation process that separated high quality from low quality ore (S. McCracken, pers. comm.). The water is a rust-red color and stains field equipment. Although we did not test for industrial contaminants such as heavy metals, pH was 8.4 (water temp = 10.1ºC, air temp 13.4ºC, RH = 52.5%). The pH optimum for *Bd* is 6–7 with less growth at a pH of 8, the highest pH tested (Piotrowski et al. 2004). Future work should examine potential linkages between environmental contaminants and the incidence and/or severity of *Bd* infections in aquatic amphibians.

Acknowledgments.—The Amphibian Disease Laboratory at the Zoological Society of San Diego is supported in part by grant LG-25-08-0066 from the Institute of Museum and Library Services. Any views, findings, conclusions or recommendations expressed in this publication do not necessarily represent those of the Institute of Museum and Library Services. Thanks to Ruffner Mountain Nature Preserve for use of their pond, S. McCracken for providing history of the area, and J. R. Mendelson III for suggesting the collaboration.

The amphibian disease chytridiomycosis, caused by the pathogenic fungus *Batrachochytrium dendrobatidis* (*Bd*, Longcore et al. 1999), is well known as a major threat to amphibians resulting in mass die-offs and population declines throughout the world (Berger et al. 1998; Blaustein and Keisecker 2002; Daszak et al. 2003; McCallum 2005; Rachowicz et al. 2006). *Batrachochytrium dendrobatidis* has been detected on amphibians from sites across North America (Ouellet et al. 2005; Woodhams et al. 2008) and appears to be most prevalent in the western and the northeastern United States (Longcore et al. 2007; Schlaepfer et al. 2007). Whereas infected anurans also have been found throughout the southeastern US (Green and Dodd 2007), there have been no reports of *Bd* from amphibians in eastern Texas, a broad area encompassing 10,000,000 ha. We sampled amphibians for the presence of *Bd* in four National Forests in eastern Texas (approximately 31°N latitude).

Amphibians were sampled for *Bd* from 9 January to 27 May 2009 in the Angelina, Davy Crockett, and Sabine National Forests, and the Stephen F. Austin Experimental Forest (Fig. 1). The Stephen

F. Austin Experimental Forest is a disjunct unit of the Angelina National Forest, administered by the Southern Research Station, US Forest Service. The dominant habitats of these areas include secondary growth Loblolly (*Pinus taeda*), Longleaf (*P. palustris*), and Shortleaf (*P. echinata*) upland pine forests and mixed deciduous bottomland forests. East Texas experiences occasional freezing temperatures, warm winter days, and extremely hot summers (Chang et al. 1996). From 1901 to 1993, the overall mean air temperatures for January and August are 8.4°C and 27.8°C, respectively (Chang et al. 1996). In winter, cold air masses often meet warm moist air pushed up from the Gulf of Mexico resulting in frequent rain events, placing the study sites in one of the wettest regions of Texas (Bomar 1995).

We searched for amphibians near ponds, streams, moist lowland areas, and upland pine forest habitat. We captured specimens by hand. Each individual was handled with a new pair of sterile nitrile gloves. We sampled for *Bd* by rubbing a sterile cotton swab on the dorsum, ventral surfaces, and feet of each frog for approximately 30 seconds, after which the animal was released at its place of capture. The swab was then immediately placed in a sterile microcentrifuge tube containing 1 ml of 70% ethanol and later sent to Pisces Molecular Laboratory (Boulder, Colorado, USA) for PCR analyses. Global positioning system (GPS) coordinates were taken at each capture site using a Garmin® GPS unit.

Overall, we sampled a total of 266 adult amphibians of 18 different species, from 8 different families (Table 1). Of these 18 species, six had at least one individual that tested positive for *Bd*. Thirteen of the 266 individuals tested positive for an overall detection rate of 4.8%. The Stephen F. Austin Experimental Forest had the highest detection rate among the four areas sampled, with six of 80 (7.5%) individuals testing positive for *Bd* (Table 1). During sampling, no sick or dead frogs were observed at any sites.

We found similar *Bd* detection rates for anurans and caudates (4.93% and 4.76%, respectively), although the only salamanders to test positive for *Bd* were three individuals of *Eurycea qudradigitata* from the Stephen F. Austin Experimental Forest. Despite 34 ambystomatids being sampled, none tested positive for *Bd*.

Five of the 15 (33.33%) *Pseudacris fouquettei* samples tested positive for *Bd*, which was the highest detection rate among anuran species, including species which were breeding at the same time and place where the *Bd*-positive *Pseudacris fouquettei* were found. Individuals of both *P. crucifer* and *Lithobates sphenocephalus* were collected at locations where *Bd*-positive *P. fouquettei* were found, yet no *L. sphenocephalus* and only one of 30 (3.33%) *P. crucifer* samples tested positive for *Bd*. However, small sample sizes make it difficult to assess whether there is actually a higher detection rates among *P. fouquettei* than other species.

Batrachochytrium dendrobatidis has been present in North American amphibian populations since at least the early 1960s (Ouellet et al. 2005). Yet, within the United States, *Bd* has been associated with amphibian die-offs predominantly in western states (e.g., Bradley et al. 2002; Briggs et al. 2005; Muths et al. 2003).

Although the fungus is present in the southeastern United States, to our knowledge no amphibian declines have been attributed to chytridiomycosis in this region. Several studies have detected higher rates of *Bd* infections during the fall or winter months (McDonald et al. 2005; Ouellet et al. 2005; Retallick et al. 2004), a phenomenon possibly explained by the fact that amphibian immune systems function less effectively at cooler temperatures (Carey 2000; Cooper et al. 1992; Maniero and Carey 1997). It is possible that the immune systems of amphibians inhabiting eastern Texas are more capable of resisting *Bd* infections because of the relatively warm winters and hot summers.

Also, it is possible that the fungus may never reach an epizootic state in eastern Texas because the warm air temperatures are less than optimal for *Bd* growth and infection of amphibians (Kriger and Hero 2006; Longcore et al. 1999; Retallick et al. 2004). Evidence for an enzootic state includes the relative low incidence of detection in PCR samples and the fact that no sick or dead frogs were encountered. Amphibians appeared to be abundant at all four of our study sites. Follow-up population and *Bd* sampling is needed to confirm what impacts *Bd* may be having on the National Forests in Texas.

Acknowledgments.—We thank T. Hall, T. Cotten, S. Wahlberg, and R. Adams for assisting with field sampling. Also, we thank C. Adams, D. Laurencio, K. Floyd, and an anonymous reviewer for constructive comments on an earlier draft of this manuscript.

Very Early Photographs of Reptiles

MANFRED NIEKISCH
Frankfurt Zoo, Bernhard-Grzimek-Allee 1
60316 Frankfurt, Germany
e-mail: manfred.niekisch@stadt-frankfurt.de

Following a publication by John Edwards in *Herpetological Review* (1998) of three early photographs of living reptiles, dated 1865, Kraig Adler and Harold Cogger (1998) presented another, even older photograph. It shows the German-born herpetologist Gerard Krefft with three live reptiles and was taken in the year 1864 by the Sydney photographer William Hetzer. Adler and Cogger invited readers to a contest to find the earliest photograph of a living reptile. Herein, I follow this invitation and contribute to the contest.

Francis Frith was born in 1822 in Chesterfield, Derbyshire, England. Not very successful at school and in an apprenticeship in a cutlery, he had a nervous breakdown, then traveled a few years in his home country, and in 1850 he set up his own printing business in Liverpool. That business thrived and he sold it in 1856 to his major competitor. The substantial profit he realized made him independent and he started his career as a photographer with a first trip to Egypt in this very year. His inaugural book, "Egypt and Palestine Photographed and Described," began to appear in 1858 and was completed in 1860, consisting of 25 parts with 76 albumen prints altogether. Among these photographs there is one of a living adult crocodile, *Crocodylus niloticus*, on a sand bank presumably along the Nile River (Fig. 1). It was taken in 1857 as can be seen from the remark "Frith-Photo, 1857" underneath the published photograph in the first volume of his two-volume book. Frith writes: "I am satisfied that they never attack mankind openly, although, no doubt, if they had an opportunity of seizing a man without exposing themselves, they would be dangerous." The main objects of Frith's photographs are buildings (both antique and contemporary) and landscapes. Only very few of his studies portray wildlife (such as a dead flamingo in the hands of an Arab "sportsman" and a cook). This is understandable also in the light of the fact that wildlife move and photographic equipment then posed serious technical limitations to wildlife photography. A large crocodile resting on a sand bank seems to be the ideal object, presenting—as compared to birds and mammals—several advantages for early photographers from this point of view. So for now this seems to be the oldest known photograph of a *living* reptile.

FIG. 1. The precise location in Egypt where Frith took this photograph of a *Crocodylus niloticus* is unknown. Additionally, it is not known if he was aware that he was perhaps the first photographer to take a picture of a living reptile.

The earliest photograph of a *herpetological specimen* I found is even older and falls in the earliest times of photography. It shows two stuffed specimens of monitor lizards, indicated below the photograph as "Varanus Bellii Duméril et Bibron" and "Varanus Varius. Merrem. Duméril et Bibron" (Fig. 2). Both are referable to *Varanus varius* (White, 1790). The two *Varanus* are clearly identifiable as dead specimens. The left one shows a crack in the skin above the left foreleg and the stuffing material is visible inside it. This photograph was first published in March 1853 in an atlas of zoological photographs which was meant to document and show the treasures of the Museum of Natural History in Paris ("Photographie zoologique ou Représentation des Animaux Rares des Colections du Muséum d'Histoire Naturelle") by L. Rousseau and A. Devéria, and then again published in 1854 in the *Bulletin de la Société d'Encouragement pour l'Industrie Nationale, Paris* (Vol. 53, Ser. 2, Volume I). This *Bulletin* is as a historical source at least as interesting as the atlas itself because it contains two articles directly relevant here. First, there is an article (pp. 117–119) by Claude Félix Abel Niepce de Saint-Victor (1805–1870). He was the son of the first cousin of Joseph-Nicéphore Niepce (1765–1833) who is considered to be the inventor of photography, as he was the first one to take a picture with a camera obscura and to get it fixed and light resistant on a metal plate. Niepce called this technique heliogravure as it was "written with sunlight." In this article entitled "Gravure héliographique," Abel Niepce describes some improvements to Joseph-Nicéphore's process (referring to him as his "uncle") developed by him together with the engraver Augustin-François Lemaître (1797–1870) who had already worked with Joseph-Nicéphore Niepce doing the etchings. After the death of Joseph-Nicéphore Niepce it was Louis Daguerre (1787–1851)—who had worked with both Joseph-Nicéphore and Abel Niepce—to develop Niepce's invention further and to bring it to a commercial stage. This Daguerrotype process was presented formally to the French Academy of Science and finally bought by the French Government as a "gift to the world" in 1839.

Abel Niepce's article is followed by one on "Photographie zoologique," written by Louis Pierre Rousseau and Achille Devéria (1800–1870), the authors of the atlas with the same title, which relates the history of this atlas.

According to their article, the first plates of photography applied to natural history ("photographie appliquée aux sciences naturelles") were received by the Académie des Sciences in Paris on March 14, 1853. Indeed, the minutes of the meeting of the Academy (Compte Rendu des Séances de l'Académie des Sciences, Tome trente-sixième. Janvier – June 1853, p. 500) state that these two gentlemen presented at the meeting "divers spécimens

FIG. 2. The caption to this photograph published in the "Bulletin de la Société d'Encouragement pour l'Industrie Nationale (1854)" differs from that in the atlas "Photographie zoologique" (1853) in the following: While here above the indication of the animals the artists involved are mentioned (from left to right): Négatif par Bisson - Photographié sur acier par Mme Pauline Riffaut - A. Riffaut sculp, in the atlas this line is lacking and below the animal description the photographers and editing companies are indicated (from left to right): Bisson fréres Photographes - Paris, chez Masson_Londres, chez Gambart - Lemercier, Paris.

Note the crack in the skin of the left specimen showing the stuffing material.

de photographie appliquée aux sciences naturelles" and that these plates, printed on paper, showed skeletons or parts thereof and other complete individuals belonging to the principal divisions of the animal kingdom.

The Bisson brothers had produced the negatives and Pauline Riffaut transferred the pictures to the steel plates. Once the acid had etched the metal plate, it was still necessary to do the finishing by hand, which was done by engraver A. Riffaut who is the third party mentioned under the prints.

In the session of June 6, 1853, the commission consisting of the zoologists Isidore Geoffroy Saint-Hilaire (1805–1861) and Achille Valenciennes (1794–1865), Henri Victor Regnault (1810–1878), a chemist and physicist who became in 1854 the founding president of the Société Française de Photographie, and zoologist Henri Milne Edwards (1800–1885) as the rapporteur received the report of Rousseau and Dévéria on the completed, but not yet edited, work and discussed it. The minutes (Compte Rendu des Séances de l'Académie des Sciences, Vol. Janvier - June 1853, pp. 991–994) give a very good idea of the enthusiasm with which the work was received. For example found the committee that even the best painter would not have the patience and ability to make visible all the details and structures of the polypes visible in the photograph which shows the object enlarged (as compared to natural size). The committee discussed the potential and advantages of the new technique at length, but it was also said that there was still something left to do by the authors to give their work the "stabilité désirable." The committee expressed confidence that the authors, with the appropriate instruments and means at their disposition, would soon reach results very useful to science, and vividly wished that photography becomes of "emploi usuel pour les zoologists." Rousseau was then "aide-naturaliste" at the Museum while Dévéria was artist at the Bibliothèque impériale.

Both *Varanus* specimens shown in the photograph (Fig. 2) are still extant in the collection of the Muséum d'Histoire Naturelle (MNHN) in Paris and registered as "*Varanus varius* (White, 1790)," the left one—ocellated, number 2—in the photograph bearing number MNHN 8284 (formerly 1551), the right one—banded, number 1—MNHN 8281 (formerly 1560), and were collected between 1842 and 1847 in "Nouvelle-Hollande" (New Holland) by Jules Pierre Verreaux (1807–1873) (Roger Bour, in litt.). Verreaux was a famous French biologist, collector of and professional trader in a wide range of natural history specimens and the Muséum d'Histoire Naturelle in Paris was a good client of his. In 1864 he obtained the position of an assistant naturalist there.

Dead animals, here in the form of two *Varanus*, or a lazy, sun-basking crocodile certainly were ideal objects in the early times of photography, given the required long exposure time. Interestingly enough, this (as far as is known) first photograph of a living reptile was taken during an expedition which was described by Manchip White (1980) as the "world's first methodically planned and executed safari" while the production of the even earlier photograph of dead reptiles described here directly involved true pioneers of photography and was published in the first book on zoological photography ever issued.

Acknowledgments.—I thank Kraig Adler for comments on the manuscript, Roger Bour for the information on the two *Varanus* in the MNHN collection, and Jasper Köcke for drawing my attention to the Frith publication containing the crocodile photograph.

The marsupial frogs (Family Hemiphractidae) from Latin America are some of the most intriguing anuran species known. As their name implies, females of these frogs bear a dorsal pouch in which they carry eggs, tadpoles, and/or froglets. In this family, there are 93 species contained in five genera ranging from Costa Rica through South America to Brazil and northwestern Argentina (Frost 2009). The natural history and reproductive behavior of marsupial frogs is well documented in only a few taxa, mostly through wild-collected specimens brought into captivity at different stages. *Flectonotus pygmaeus*, *Gastrotheca riobambae*, and *G. argenteovirens* were observed in the field and laboratory (Duellman and Maness 1980). The Ecuadorian species *G. riobambae*, has been the most heavily studied by far. This species carries eggs until they develop into tadpoles (taking up to 120 days) that are released into a small body of water (usually a shallow depression or pond). Reproduction in captivity has been reported and has afforded several opportunities for documentation of breeding, gestation, and parturition (Auber-Thomay and Letellier 1986; Boonman 1985; Fitzgerald et al. 1979). Reproduction of *Gastrotheca plumbea* was also observed in the laboratory, including the positioning of eggs in the pouch of the female and birth of fully formed froglets (Auber-Thomay et al. 1986).

Differences in gestation times, fertility, and pouch morphology among taxa have been reviewed along with role of the male in assisting with inserting eggs into the pouch in *F. pygmaeus* and *G. riobambae* (Duellman and Maness 1980).

FIG. 1. Adult Horned Marsupial Frog *Gastrotheca cornuta*. Photo by Brad Wilson.

We recently began working with captive populations of the Horned Marsupial Frog, *Gastrotheca cornuta* (Boulenger 1898; Fig. 1). Historically, this species ranged from Costa Rica to Ecuador; however, in many localities, it has become increasingly rare during the past two decades.

In the field, *G. cornuta* is difficult to encounter. It is thought that this shy species stays high in the canopy of old growth forests, far from anthropogenic disturbance. Juveniles are hardly ever encountered and adults only rarely. In El Valle de Antón, Provincia de Coclé, Panama, we encountered two gravid females (eggs visible through the skin of the abdomen) and one female with eggs inside the pouch in primary forest in close proximity to the Río María ca. 1.5 m above the forest floor during June and July 2005. In June 2006, we observed an amplectant pair of *G. cornuta* ca. 10 m above the ground. Newly emerged froglets have not been found to date in this area. However, in early 2006, we encountered two juveniles ca. 2 m above the ground; these may be offspring born in late 2005.

Marsupial frogs exhibit multiple modes of parental care depending on species (Duellman 1970). In some species, such as *G. riobambae*, the female parent carries tadpoles in the pouch until they are released at late stages of growth into a water source. In other species, the female carries and delivers fully developed froglets, as in the case of *G. cornuta*. Considering all species of *Gastrotheca* and *Flectonotus*, there are six morphological pouch types based on size, position, and degree of coverage (del Pino 1980; Mendelson et al. 2007). The evolution of each of the differing types of pouch morphology and reproductive behavior bears further study for contributions to the science of natural history, evolution, and phylogenetics. Application of these findings to captive reproduction will have implications for *ex situ* conservation and potentially survival of threatened species.

The pouch develops from the skin of the dorsum and can extend nearly up to the back of the skull or even to the lateral lymph spaces. After eggs are inserted into the pouch, usually by the male, the interior skin of the pouch becomes vascularized and in some cases

FIG. 2. Enclosure for maintaining *Gastrotheca cornuta*. Photo by Robert Hill.

forms partitions between embryos (del Pino 1980). Species, such as *G. cornuta*, that undergo direct development of eggs to frogs within a pouch, exhibit an interesting example of a life history completely free of any significant body of water—a method far removed from the plesiomorphic and most common amphibian strategy involving the deposition of eggs directly into water (Wells 2008). Presumably this life history allows species to live under less than favorable environmental conditions with respect to availability of bodies of water, and may reduce exposure of developing offspring to water-borne threats such as predation or disease. Wells (2008) provided a thorough summary of the evolutionary and ecological aspects of this important question, and Todd (2007) proposed an important role of disease and parasites as selective agents in the evolution of alternative reproductive strategies in amphibians.

As the scope of the crisis of global amphibian extinctions becomes clear (Stuart et al. 2004) and the threat of emerging infectious diseases such as amphibian chytridiomycosis become more apparent (Daszak et al. 2003), a collaborative effort of the International Union for the Conservation of Nature (IUCN), Captive Breeding Specialist Group (CBSG), and World Association of Zoos and Aquariums (WAZA) has brought about the Amphibian Ark organization (www.amphibianark.org). The Amphibian Ark is dedicated to safeguarding the species that cannot currently be saved in nature; this is accomplished by managed breeding programs to safeguard species while threats can be further mitigated. In some cases, managed populations may serve as a stopgap for many species heading for extinction. The IUCN Amphibian Conservation Action Plan (Gascon et al. 2007) specifically calls for captive breeding and research programs for threatened amphibians. The use of captive breeding programs as a conservation tool is not new and summaries can be found in Zippel et al. (2002) and Gagliardo et al. (2008).

As chytridiomycosis entered the range of *G. cornuta* (Lips et al. 2006), adversely affecting this and other species (Gagliardo et al. 2008), a conservation breeding program was launched. In 2005, specimens of *G. cornuta* were legally exported from Panama to the Atlanta Botanical Garden (ABG), and in 2006 similar specimens were collected and moved to the El Valle Amphibian Conservation Center (EVACC) in El Valle de Antón, Panama. Here we present an overview of our program, some interesting behavioral observations (e.g., toe tapping, male and female vocalizations, egg fertilization and deposition), along with husbandry challenges for long-term care in captivity we have encountered.

Results at the El Valle Amphibian Conservation Center in Panama

Adults at EVACC were maintained in top-opening glass enclosures (60 cm × 30 cm × 40 cm). The substrate consisted of a "false bottom floor" constructed of plastic light diffuser material covered with soft fiberglass screen secured in place with plastic "zip" ties. Non-bleached paper towel was used as covering on the bottom of this false bottom. Potted plants including *Philodendron* and *Heliconia* were added along with pieces of cork bark or half-inch PVC for refuge and perching sites. Two 96-watt power compact fluorescent lights provided lighting and the temperature was maintained at 23–25°C. The frogs were misted automatically 10 times daily with filtered water. Males and females were housed separately until breeding attempts were made, at which time a male was introduced in late afternoon to the female's enclosure. The male vocalized occasionally during the day but mostly in the early evening and throughout the night. All adults were fed katydids (*Neoconocephalus saturatus*) every other day. Because of observed cannibalism, the males were kept individually until placed with a female. On several occasions we noted that the dominant male would attempt to consume another male. In one case, the whole front limb (all the flesh off the bones) and part of the back (partially) of the less dominant male were partially digested. During this process the less dominant male (attributed to its proclivity to hiding rather than perching in the open) was still alive despite being partially digested by its cage mate.

Information on specimens used in breeding event:

Female *Gastrotheca cornuta* (EVACC 001-3) was collected from Río María on 17 June 2006 (found in amplexus with a male) and male *G. cornuta* (EVACC 001-5) collected (also from Río María) on 20 June 2006.

Female history:

On 29 December 2006, the female (EVACC 001-3) was observed to be gravid. Different males (EVACC 001-8, 001-7, and 001-6) were placed with the female individually over the course of several weeks but removed when the male did not amplex the female. On 28 January 2007 amplexus was noted with male EVACC 001-6. On 4 February 2007 the female had eggs in her pouch. Fertiliza-

tion was not observed. On the morning (0800 h) of 20 April 2007, froglets (N = 14) were observed in the enclosure along with two incompletely formed young that were apparently aborted.

2008 Breeding event:

21 February: Male *G. cornuta* (EVACC 001-5) placed in tank with resident female (EVACC 001-3).

22 February: Male and female observed in axillary amplexus. Male had all hand digits in axillary position except one (unclear exactly which due to position and ambient light levels), which was on top of female's front limb.

23 February, 1429–41 h: Male and female observed in axillary amplexus on paper towel at bottom of terrarium. Male arched hind limbs to about a 50° angle while female started to rock (i.e., pushing movement) for about 10 seconds (s). Female maintained front limbs out in front of her, underneath her body (i.e., "praying" position). Male maintained the 50° position for about 5 s, and then settled in so that his legs were held tightly against his body, with his head resting perfectly on top of female's head.

1441–49 h: Male placed his feet on female's back and pushed hind limbs in the air in a 50–60° angle. The male inflated himself, and then raised his legs so that his heels were touching, and maintained position for about 10 s. Female remained motionless during this time, until 1449 h when she pushed against the ground with her back limbs, while the male moved his limbs slightly (15° angle).

1450 h: Male inflated and engaged in movement for 45 s.

1510 h: Female's cloaca reddened and pushed out with male's movement.

1512 h: Male inflated again and engaged in movement for 4 s.

1514 h: Appeared as if the male's movements were an attempt to help the female push out eggs. Female's cloaca tilted upward and aligned with male's swollen cloaca. No egg was released but male moved his hind leg as if to find an egg.

1519–24 h: Male inflated, then female moved her hind legs to 45°. Male inflated again, and then female's cloaca could be seen moving in a pulsing manner.

1525–29 h: Female lifted cloaca. Male touched female cloaca (raising hind limbs) with his left toes making sweeping motion on female's back. Male's feet (toes) were in the vicinity of female's pouch. Female then spread her hind limbs a bit farther apart and assumed a broader stance.

1530–34 h: Male inflated, then deflated, and a gel-like substance appeared. It was not clear if this originated from the cloaca or from the skin. It appeared that the male was glistening first and then after some time it was apparent that the female was coated with this substance as well. The male rubbed substance all over the lower back and pouch of the female with his toes.

1535–54 h: Male began cycles of inflation and deflation. Female moved forward and moved her hind legs; they still maintained a 45°angle but heels were now closer together. Male proceeded to rub the gel-like substance all over the female with his toes.

1555–1601 h: Female rearranged her feet, first right then left in a motion (position) similar to as if preparing to jump. Male and female cloacas aligned with each other. Male continued cycles of inflation and deflation, and continued to spread gel over female's body with his toes. The side of female glistened with the gel-like substance. Male's body was also covered by the substance, which did not appear to dry.

1602–05 h: Female's body was observed to contract. Female pushed forward while the male rose up and down (but did not inflate). Male moved his cloaca into a position directly dorsal to female's cloaca.

1607–14 h: Female arched body, raising her cloaca above the angle of her feet, and cycles of body contractions were observed. Male continues to inflate and deflate. Male then slid forward, pushing female downward and continued to spread the gel over her.

1617–22 h: Male continued inflating and deflating, and rubbing the gel over female with his feet. Then a round egg could be seen in the aperture of female's cloaca. Female rearranged her hind legs, and raised her cloaca while male inflated and deflated. Male moved to bring his cloaca in alignment with that of female.

1628 h: Male deflated. Egg inside of female's cloaca slightly visible as male pushed down. Male moved his toes toward female's pouch.

1630–53 h: Female's body continued with cycles of contractions, and male continued to inflate and deflate. The egg could be seen alternately appearing and disappearing at the aperture of females' cloaca.

1655 h: First egg emerged from female's cloaca, while her body appeared to be in a strong contraction. Male cradled the egg with his body, and maneuvered it into female's pouch with his hind toes. Male continued to inflate and deflate.

1701 h: Male pushed down on female. A second egg almost emerged from female's cloaca.

1706 h: The second egg emerged, and was pushed into the pouch by the male using his feet.

1711 h: Third egg emerged, and male trapped it with his cloaca and pushed it toward the pouch opening. Male used hind legs to position it in female's pouch.

1719 h: Fourth egg emerged, and male repeated behavior to insert it into female's pouch. It appeared as if the male's toes were inserted inside of the pouch, at least dextrally.

1724 h: Male engaged in head bobbing behavior.

1726 h: Fifth egg emerged, and male observed to insert toes into the pouch while inserting the egg.

1729–1834 h: Pair maintained amplexus, male continued to inflate and deflate and began to perform a "rocking" motion, but no additional eggs were produced. The female changed position in minor ways several times before disengaging amplexus.

Results at the Atlanta Botanical Garden

As part of a pilot study aimed at learning the logistics of an ex situ response to the rapid spread of the amphibian chytridiomycosis through pristine amphibian populations in Panama, several threatened amphibian taxa were exported to facilities at the ABG and Zoo Atlanta in 2005 (Gagliardo et al. 2008). The original breeding group of six male and two female *G. cornuta* was maintained at the ABG where several breeding events have occurred. Adults were maintained in either 60 × 30 × 60 cm or 60 × 60 × 90 cm front-opening glass enclosures for maintenance (smaller) or breeding (larger). The substrate consisted of a "false

bottom floor" constructed of plastic light diffuser material covered with soft fiberglass screen secured in place with plastic "zip" ties. Potted plants including *Philodendron*, *Heliconia*, and *Calathea* were added for hiding places. Pieces of driftwood or similar twigs were provided for perching sites (Fig. 2). Two 96-watt power compact fluorescent lights provided lighting and the temperature was maintained between 18°C and 27°C. The frogs were misted twice daily with filtered water either through an automated system or by hand sprayer bottle. A 15–20 cm diameter, 6-cm-deep shallow water dish containing smooth river stones was refreshed with clean water daily. The stones afforded a climb-out option for not only the frogs after soaking in water but also food items that happened to fall into the water. Males and females were housed separately until breeding attempts were made, at which time a male was introduced in late afternoon to the larger enclosure containing one female. Male vocalization, a very loud, single note similar to the sound of removing a cork from a bottle, was common in early evening.

The first breeding event occurred in April 2006, less than 48 h after introducing a male into a female's enclosure. Both individuals were exposed to an imposed "dry season" simulated by six weeks of slightly warmer temperatures and lower humidity achieved by less frequent misting of the enclosure and increasing ambient day time temperatures from 20–25°C. There were no signs of courting or amplexus before the female was discovered in the early morning (0700 h) on the second day after introduction of the male. Fourteen eggs appeared to have been inserted into the female's pouch (Fig. 3) and there were two infertile eggs found on the surface of a leaf in the tank. The recovered eggs were approximately 1.0 cm in diameter, not unexpected as this species is reported to produce the largest anuran egg known (Duellman and Trueb 1986). Immediately following this breeding event, the male was moved to separate enclosure to reduce stress on the gravid female.

Video surveillance of this first attempt did not record any breeding activity but did record evident toe tapping of the female who upon sight of a live, moving cricket (*Acheta domestica*), became keenly interested in the prey and began to tap and motion with toes of her hind feet. Pedal luring (Bertoluci 2002; Murphy 1976; Radcliffe et al. 1986) and providing a vibrational stimulus resulting in prey movement and ultimately prey detection (Sloggett and Zeilstra 2008) are two hypotheses for toe twitching and toe tapping in anurans. Although toe twitching and tapping are thought to be a common behavior among many frogs and toads (Sloggett and Zeilstra 2008), and have been reported in numerous anuran genera from several different families, including Batrachophrynidae (Radcliffe et al. 1986), Bufonidae (Hagman and Shine 2008; Radcliffe et al. 1986; Sloggett and Zeilstra 2008), Dendrobatidae and Hylidae (Bertoluci 2002), this is the first documentation of pedal luring in the Hemiphractidae.

FIG. 3. Female *Gastrotheca cornuta* with eggs in pouch. Photo by Brad Wilson.

FIG. 4. Newly emerged *Gastrotheca cornuta*. Photo by Heidi Ross and Edgardo Griffith.

An additional breeding event occurred in Atlanta in the spring of 2008. On 14 April a male was introduced to an enclosure containing a visibly gravid female. Within 24 h, amplexus was observed, followed overnight by eggs being visible in the pouch. These eggs incubated until 15 June 2008 when thirteen live froglets and two infertile eggs were discovered in the enclosure.

Gestation, Birth, and Handling of Offspring

Gestation periods ranged from 60–80 days over the course of several breeding events. In the final week before froglets emerged from the pouch, it was possible to see movement of the limbs of the embryos just beneath the skin of the pouch. At both ABG and EVACC, the newly born offspring were approximately 1.0 cm in length and averaged 400 mg in mass (Fig. 4). Upon their birth, offspring were separated into individual enclosures to avoid predation by the female and offered a variety of prey items including fruit flies, houseflies, and small (3–5 mm) crickets. Food items were dusted alternately with vitamins (Men's Health® multivitamin, once per week) and calcium supplements (RepCal® with Vitamin D3, twice per week).

Abortion of Developing Offspring

Case 1: On 20 June 2007, a gravid female ca. 50 days post-breeding aborted five developing offspring and seven non-developed eggs. There were no outward physical signs of any problems prior to this event. The pouch remained partially inverted for approximately 48 h before repositioning to its normal state (Fig. 5). The developing offspring displayed long, 2–4 cm filamentous gills attached through the skin under the throat (Fig. 6).

Case 2: An abortion of eggs occurred immediately following

FIG. 5. Inverted pouch of female *Gastrotheca cornuta* less than 24 h after emergence of froglets. Photo by Ron Gagliardo.

a July 2008 breeding event. Although our attempts to record the breeding event via night-vision video were unsuccessful (likely due to disturbance caused by shifting of blinds, camera tape changes, noise, etc.) and we did not capture the breeding event on film, we did observe vocalization by the female that consisted of a single soft "bop" periodically prior to amplexus. This could be an encounter call and although we found this unusual, encounter calls have been documented in other anurans (Quiguango-Ubillús and Coloma 2008). Five eggs were never inserted into the pouch and the seven eggs successfully moved into the pouch were aborted within 72 h. We noted that in contrast to the previous case, the lining of the pouch was not extruded possibly because the pouch never became vascularized. Attempts to artificially incubate five eggs on sterile paper toweling or sphagnum moss failed and the eggs disintegrated within 24 h.

Obstacles for Long-term Captive Management

Whereas the captive reproduction of *Gastrotheca cornuta* proved much less difficult than expected, raising offspring has been extremely challenging. Most losses occurred during the first 5–20 weeks after birth. Necropsy results indicated a range of issues including internal parasites (mostly rhabditiform nematodes), squamous metaplasia ("short-tongue syndrome" possibly indicative of Vitamin A deficiency), and signs of metabolic bone disease. Currently, there are 11 captive-born offspring in existence,

FIG. 6. Partially developed offspring of *Gastrotheca cornuta* that were aborted during the final weeks of development. The bell gills that characterize this group of frogs are clearly visible. Photo by Ron Holt.

6 at EVACC and 5 at ABG. The five frogs at ABG are over one year in age, weigh between 7.1–12.7 grams and have snout–vent lengths (SVL) of 42–55 mm. Specimens appear to be in overall good health, but have grown very slowly and show some slight rear limb deformities possibly attributable to improper vitamin and mineral supplementation, and/or inadequate exposure to UV-B. At EVACC, the offspring are 12–15 months of age and five of the six also exhibit problems consistent with metabolic bone disease and other skeletal deformities. One frog, (a single survivor from a clutch that emerged on 27 May 2008) has received exposure to UV-B radiation (45 minutes daily from an Eiko® 50-watt halogen bulb with lens removed and positioned atop enclosure) and has not developed any obvious skeletal deformities. The slightly deformed animal from the first clutch born in April 2007 actively hunts and is now calling (Fig. 7). Experiments with Vitamin A supplementation and UV-B exposure currently underway are aimed to mitigate these problems. It is crucial to the survival of these colonies to decipher the husbandry issues, raise offspring to adulthood, and produce subsequent generations.

FIG. 7. Juvenile captive born *Gastrotheca cornuta* exhibiting skeletal deformity. Photo by Brad Wilson.

Conclusions and Implications for Conservation

In comparison to other anuran families such as Dendrobatidae and Ranidae, relatively little is known about the natural or captive reproduction of hemiphractine frogs. Mating behavior in captive specimens of *Gastrotheca riobambae* by Matthews (1957), Deckert (1963), and Hoogmoed (1967), as summarized by Means et al. (2009), was similar to what we have described here, in the male producing a fluid that is rubbed over the posterior area of the female (from cloacal region extending to the anterior limit of the brood pouch) and using his hind legs to insert eggs into the pouch as they are extruded. We speculate that the clear fluid observed by Means et al. (2009) and by us in Panama might have been produced by the male. We should not rule out the possibility that such secretions from the male may contain hormones or other chemicals that stimulate observed contractions in the females. In addition, the vocalization of the female during amplexus remains a mystery. Clearly, these interesting observations should be subject to future investigation.

Along with the actual physical reproductive behavior in hemiphractine frogs such as *Flectonotus* and *Gastrotheca*, we should consider how the natural history affects the developmental physiology of these taxa. Some species are known to bask only while incubating embryos, thus exposing themselves to UV-B radiation (Auber-Thomay et al. 1990). Does this suggest that eggs or developing froglets need UVB or heat for proper development? There are also reports of infection of tadpoles by rhabditiform nematodes while incubating inside the pouch (Auber-Thomay et al. 1990).

What are the Implications of Such Parasitism in the Wild or Captivity?

Over half of the 57 known species of *Gastrotheca* are exhibiting population declines (www.iucnredlist.org). The IUCN Red list categorizes *G. cornuta* as Endangered, and a more recent prioritization by the Panamanian government and the Amphibian Ark placed it among the top Panamanian species in need of *ex situ* intervention (Amphibian Ark 2009; IUCN 2009). This highly threatened status warrants continued searches in Panama and elsewhere for additional founder specimens to increase genetic variability of managed colonies. Clearly, the phylogenetically, taxonomically, and physiologically unusual masterpieces that are *Gastrotheca* (Fig. 9) are worthy of conservation efforts. In cases where threats in nature cannot be mitigated in time, managed *ex situ* populations may be the only hope for safeguarding these species until such threats are reversed or until other methods for re-establishing these species in nature are developed. Learning more about the complex natural history and physiology will certainly be of great assistance in the future conservation of these and other endangered amphibian species. We also offer that our natural history and behavioral observations presented here are unlikely to have been documented in the wild, thus supporting the claim that captive programs provide real opportunities for basic research (Chiszar et al. 1993), in this case relating to natural history and behavior. As such, these programs function as a crucial component of the "multidisciplinary approaches to conservation" (Gans 1994).

Acknowledgments.—We thank the personnel and government of the Republic of Panama including R. Ibáñez, and the staff of Hotel Campestre. Collecting permits were granted by the Autoridad Nacional del Ambiente (permit SEX/A-81-05), with considerable logistical assistance from O. Arosemana of the Smithsonian Tropical Research Institute. We also express our sincere gratitude to Ron Holt for his photographic consultation. Additionally, we thank Marcela Sepulveda Tirado, Jennifer Cruse-Sanders, and Danté Fenolio for their assistance during efforts to film breeding behaviors at Atlanta Botanical Garden. All field observations were made by EG and HR. We dedicate this paper to the memory of Julia Beth Kaylock (1980–2009), who dedicated herself to the conservation and captive husbandry of many Panamanian amphibians, including *G. cornuta*.

NATURAL HISTORY NOTES

The Natural History Notes section is analogous to Geographic Distribution. Preferred notes should 1) focus on observations in the field, with little human intrusion; 2) represent more than the isolated documentation of developmental aberrations; and 3) possess a natural history perspective. Individual notes should, with few exceptions, concern only one species, and authors are requested to choose a keyword or short phrase which best describes the nature of their note (e.g., Reproduction, Morphology, Habitat, etc.). Use of figures to illustrate any data is encouraged, but should replace words rather than embellish them. The section's intent is to convey information rather than demonstrate prose. Articles submitted to this section will be reviewed and edited prior to acceptance.

Electronic submission of manuscripts is requested (as Microsoft Word or Rich Text format [rtf] files, as e-mail attachments). Figures can be submitted electronically as JPG files, although higher resolution TIFF or PDF files will be requested for publication. Please DO NOT send graphic files as imbedded figures within a text file. Additional information concerning preparation and submission of graphics files is available on the SSAR web site at: http://www.ssarherps.org/HRinfo.html. Manuscripts should be sent to the appropriate section editor: **Marc P. Hayes** (crocodilians, lizards, and *Sphenodon*; mhayesrana@aol.com); **Charles W. Painter** (amphibians; charles.painter@state.nm.us); **Andrew T. Holycross** (snakes; AndrewHolycross@gmail.com); and **James Harding** (turtles; hardingj@msu.edu).

Standard format for this section is as follows: SCIENTIFIC NAME, COMMON NAME (for the United States and Canada as it appears in Crother [ed.] 2008. *Scientific and Standard English Names of Amphibians and Reptiles of North America North of Mexico*. SSAR Herpetol. Circ. 37:1–84, available from SSAR Publications Secretary, ssar@herplit.com; for Mexico as it appears in Liner and Casas-Andreu 2008, *Standard Spanish, English and Scientific Names of the Amphibians and Reptiles of Mexico.* Herpetol. Circ. 38:1–162), KEYWORD. DATA on the animal. Place of deposition or intended deposition of specimen(s), and catalog number(s). Then skip a line and close with SUBMITTED BY (give name and address in full—spell out state names—no abbreviations). (NCN) should be used for common name where none is recognized. References may be briefly cited in text (refer to this issue for citation format).

Recommended citation for notes appearing in this section is: Medina, P., and R. L. Joglar. 2008. *Eleutherodactylus richmondi*: reproduction. Herpetol. Rev. 39:460.

CAUDATA — SALAMANDERS

ANEIDES FERREUS (Clouded Salamander). **ARBOREAL ACTIVITY.** *Aneides ferreus* inhabits the forests of western Oregon and extreme northwestern California. Although thought to be primarily terrestrial, *A. ferreus* has occasionally been found as high as 60 m up in trees (Jones et al. 2005. Amphibians of the Pacific Northwest. Seattle Audubon Society. 227 pp.), and two recent reports suggest that it may be more arboreal than previously believed (Spickler et al. 2006. Herpetol. Conserv. Biol. 1:16–26; Forsman and Swingle 2007. Herpetol. Conserv. Biol. 2:113–118). However, it is difficult to evaluate the amount of arboreal activity by this species because almost all sampling efforts have been focused on terrestrial habitats.

On 23 May 2008 near the Coquille River in southwest Oregon we observed two adult *A. ferreus* in a cavity 75 m above ground in a Douglas-fir tree (*Pseudotsuga menziesii*) that was 78 m tall and 195 cm diameter at breast height (43.1797°N, 123.8122°W; WGS 84). Exposed when a limb broke off, the small cavity in the trunk contained copious amounts of Red Tree Vole (*Arborimus longicaudus*) fecal pellets. Two days later we photographed what we presumed to be the same two salamanders in the cavity (Fig. 1). Based on the shape of their heads, we suspected they were a male and female. These observations add to the increasing evidence that *A. ferreus* is more active in the canopy of Douglas-

FIG. 1. *Aneides ferreus* inside a cavity 75 m above ground in the top of an old-growth Douglas-fir (*Pseudotsuga menziesii*), Coquille River, Oregon, USA.

fir forests than is generally known and also support the hypothesis that nests of arboreal rodents may be important microhabitats for *A. ferreus* (Spickler et al. 2006, *op. cit.*; Forsman and Swingle 2007, *op. cit.*). It remains unknown if use of the forest canopy by *A. ferreus* is restricted to foraging and shelter, or includes occasional breeding as well.

CRYPTOBRANCHUS ALLEGANIENSIS ALLEGANIENSIS (Eastern Hellbender). **SECRETION PRODUCTION.** Of the potential antipredator mechanisms exhibited by amphibians, noxious skin secretions are considered the most effective against potential predators (Brodie et al. 1979. Copeia 1979:270-274). Many species produce toxic and irritating skin secretions as adults, but the larvae of many salamanders are palatable to various predators because toxic and distasteful secretions generally do not develop until after metamorphosis (Formanowicz and Brodie 1982. Copeia 1982:91–97).

FIG. 1. Larval Eastern Hellbenders (*Cryptobranchus alleganiensis alleganiensis*) immediately after producing a white secretion composed of sticky and foamy components.

Adult *Cryptobranchus alleganiensis* are large amphibians (60+ cm) and probably have few predators. When stressed or being captured, adult hellbenders often produce a milky secretion that is bitter and distasteful when applied to the tongue (Brodie 1971. Herpetol. Rev. 3:8), and the secretion may be unpalatable to predators. Larval hellbenders hatch between 23 and 30 mm total length and metamorphose 1.5–2 yrs after hatching, and are probably highly vulnerable to predation due to their small size and slow developmental rate (Nickerson and Mays 1973. The Hellbenders. Milwaukee Public Museum. Wisconsin. 106 pp.). It is unknown when the ability to produce secretion develops in hellbenders. In Oct–Nov 2007 several Eastern Hellbender egg clutches were collected in Missouri for captive rearing. On 29 April 2008 at 0900 h, 12 larval hellbenders (25 weeks post hatching, mean TL ± SE = 91.75 ± 1.8 mm) were collected in a small net for transport to a separate container for behavioral observations. The larvae immediately produced copious amounts of a secretion that appears to have two components. The first component was water-soluble and had a "foamy soap" appearance (Fig. 1). The second component was very sticky and was not soluble in water (Fig. 1); it remained adhered to the individual hellbenders for up to 48 h. Both components are similar in appearance to those produced by adult hellbenders (Nickerson and Mays 1973, *op. cit.*).

Immediately after secretion production, BGG put a small amount of the foamy secretion on his tongue and experienced a strong bitter sensation lasting for ca. 5 sec. The sensation was not accompanied with burning or numbness. The larval secretion tasted very similar to that produced by adult hellbenders.

Our observations suggest that, unlike most salamanders with aquatic larvae, larval hellbenders are capable of producing noxious skin secretions that might function to deter potential predators.

SIREN INTERMEDIA (Lesser Siren). **DROUGHT SURVIVAL.** Adult sirens are able to survive prolonged exposure to drought conditions with larger animals being more successful at surviving laboratory-induced aestivation than smaller conspecifics (Gehlbach et al. 1973. Am. Midl. Nat. 89:455–463; Etheridge 1990. Herpetologica 46:407–414). Larger Greater Sirens (*Siren lacertina*) can possibly survive droughts for 2–3 years and very small sirens (~1 g) are likely able to survive droughts of 146 days (Etheridge 1990, *op. cit.*). Despite the numerous reports of aestivating sirenids in the literature, it remains unknown whether small, young of the year sirens can survive short drought conditions under field conditions. In 2007, many isolated wetlands on the Savannah River Site in Barnwell County, South Carolina, USA, dried completely as a result of a severe drought in the southeastern United States. Even some of the most permanent wetlands on the site dried completely for the first time in nearly 10 years. One of these semi-permanent wetlands, Craig's Pond, is a 72.8-ha Carolina Bay wetland that is the largest natural bay on site. We visited Craig's Pond on 23 Feb 2008 from 2100–2300 h after a series of heavy rains passed through the area. There was a film of dried organic matter floating on the surface of the bay that was presumably formed when the bay dried, the water was uncharacteristically clear and the bottom of the wetland was still comprised of cracked mud and (now submerged) green terrestrial grasses (indicating that the water in the wetland was mostly, if not all, from recent rainwater). During this time, we saw a few *Siren intermedia* moving along the wetland bottom. Judging from Gehlbach and Kennedy's (1978. Southwest. Nat. 23:423–429) estimates of year class data, these were likely individuals that would have hatched in 2006 (~20 g). On a subsequent visit on 12 March 2008 from 2100–2300 h we captured two *S. intermedia* that were yearlings from 2007 (~5 g) and sighted several more small sirens. The presence of the two smallest size classes from the previous year's population in Craig's Pond indicates that even the smallest *S. intermedia* were able to successfully survive a short term wetland dry down from ca. November 2007 to February 2008. Additionally, many fish were present in Craig's Pond prior to the drought, including Redfin Pickerel (*Esox americanus*), and cyprinids. Despite several person-hours of searching on both nights, no fish were seen. This suggests that no temporary waterways connected Craig's Pond with other water sources where fish or sirens may have persisted. Consequently, it is likely that the small sirens we observed in Craig's Pond were in fact drought survivors and not dispersers from connected waterways. To our knowledge, this is the first record of juvenile sirens surviving drought conditions in the field.

We thank John Maerz and the University of Georgia's Herpetology class of 2007. Salamanders were captured under scientific research permit 56-2003 from the South Carolina Department of Natural Resources. Funding for this research was provided by the Savannah River Ecology Laboratory under Financial Assistance Award DE-FC09-96SR18-546 between the University of Georgia and the U.S. Department of Energy.

ANURA — FROGS

AGALYCHNIS CALLIDRYAS (Red-eyed Treefrog). **EGG PREDATION**. Red-eyed Treefrogs are found in low elevation tropical forests from the southern Yucatan through Panama. Females deposit clutches of eggs on leaves that overhang ponds, and eggs spontaneously hatch after 5–8 days (Savage 2002. The Amphibians and Reptiles of Costa Rica: A Herpetofauna Between Two

FIG. 1. Upper: Juvenile *Cupiennius getazi* in close proximity to a clutch of *Agalychnis callidryas* eggs. Lower: Close-up of spider consuming the developing embryo.

Continents, Between Two Seas. Univ. Chicago Press, Chicago, Illinois. 934 pp.). Eggs are often attacked by aerial (wasp: Warkentin 2000. Anim. Behav. 60: 503–510) and arboreal (snake: Donnelly and Guyer 1994. Oecologia 98:291–302; Warkentin 1995. Proc. Natl. Acad. Sci. USA 92:3507–3510) predators. Here we present an account of predation of an *Agalychnis callidryas* embryo by a spider.

While conducting field work in the Researcher's Swamp at La Selva Biological Station near Puerto Viejo de Sarapiqui, Costa Rica, we observed a spider occupying a territory (i.e., seen on consecutive days within a limited area) on a leaf that contained a clutch of *A. callidryas* eggs (26 June–1 July 2008). On the fourth day after oviposition, the spider appeared to defend the clutch by moving rapidly into a position on top of the eggs as we approached. The following evening (28 June, ca. 2200 h), we witnessed the spider consuming one of the embryos from the egg clutch (Fig. 1). Although vibrational cues are known to trigger hatching in *A. callidryas* eggs (Savage 2002, *op. cit.*; Warkentin 2005. Anim. Behav. 70:59–71), none of the eggs hatched during this predation event. Before the onset of spontaneous hatching (1 July), we collected and preserved the spider, and it was later identified as a juvenile *Cupiennius getazi* (Family Ctenidae).

This is the first account of spider predation on eggs of *A. callidryas*, and to our knowledge, the only account of a spider consuming amphibian eggs. The spider was deposited at the La Selva Biological Station Museum (collection code MG.08,06; specimen LS814539). We thank Carlos Viquez (INBio, Costa Rica) for identifying the spider.

Submitted by **MEGAN E. GIBBONS** (e-mail: mgibbons@bsc.edu), **KIMBERLY P. FARRIS** (e-mail: kpfarris@bsc.edu), and **PETER A. VAN ZANDT** (e-mail: pvanzand@bsc.edu), Birmingham-Southern College, Department of Biology, Box 549022, Birmingham, Alabama 35254, USA.

BUFO MELANOSTICTUS (Asian Common Toad). **RECORD SIZE**. *Bufo melanostictus* is known to be the largest toad in South China, attaining an SVL of "about 10 cm" (Karsen et al. 1998. Hong Kong Amphibians and Reptiles, Provisional Urban Council, Hong Kong, China). The largest published record available is 106 mm SVL (Fei [ed.] 1999. Atlas of Amphibians of China, Henan Science and Technology Press, Zhengzhou, China). On 11 Aug 2008, at night after a rain at Wuzhi Shan (Five Finger Mountain) National Nature Reserve (18.83333°N, 109.55°E; ca. 900 m elev., WGS 84), Hainan Island (Province), we captured a female toad of great size. Pressed flat on a table, snout tip against the wall, she measured 115 mm SVL (relaxed view: Fig. 1). Identity of the species, gender, and measurement were verified by James Lazell. We had no collecting permit and released this toad to grow even larger. The photograph is accessioned at the Museum of Comparative Zoology (MCZ K-959). Our field work was sponsored in part by the Falconwood Foundation and by the grant from the Natural Science Foundation of Guangdong Province (No. 06025054). We thank J. Rosado and J. Lazell, MCZ, for photo accession assistance.

CENTROLENE PROSOBLEPON (Glass Frog). **REPRODUCTION.** *Centrolene prosoblepon* is a neotropical frog ranging from Honduras to Ecuador (Frost 2008. Amphibian Species of the World, ver. 5.3. <http://research.amnh.org/herpetology/amphibia/index.html> Accessed 14 Aug 2008). There are no data available on reproductive characteristics of this species including the number of the egg per clutch, egg size, and color of embryos at an early stage of development, i.e., less than Gosner Stage 10 (Gosner 1960. Herpetologica 16:183–190). Herein, we report this information collected near Falan (5.11666°N, 74.96666°W; WGS 84), Tolima, Colombia. Between November 2007 and May 2008, we found more than 200 egg clutches of *C. prosoblepon* laid on the top of leaves over a stream along a 600 m transect. Of these, we collected data from 40 clutches. We recorded an average of 32 eggs per clutch

FIG. 1. Egg clutch of *Centrolene prosoblepon* from near Falan, Tolima, Colombia.

(range: 25–47), mean diameter of the eggs was 2.56 mm (N = 27), and all embryos were pale yellow (Fig. 1).

Submitted by **MANUEL HERNANDO BERNAL BAUTISTA** (e-mail: mhbernal@ut.edu.co), **EVER EDREY HERNÁNDEZ-CUADRADO** (e-mail: edouglas09@hotmail.com**)**, and **MANUEL GILBERTO GUAYARA BARRAGÁN** (e-mail: jaimar74@gmail.com), Laboratorio de Herpetología and Eto-Fisiología. Universidad del Tolima, Ibagué, Colombia.

CENTROLENE PROSOBLEPON (Glass Frog). **FUNGAL INFECTION.** Amphibian decline is a global phenomenon caused by multiple factors (Stuart et al. 2004. Science 306:1783–1786). Some declines have been attributed to the infectious disease caused by the fungus *Batrachochytrium dendrobatidis*, which is found in the oral disc of larvae and the skin of adults (Zellmer and Richards 2008. Herpetol. Rev. 39:196–199; Zippel and Tabaza 2008. Herpetol. Rev. 39:192–193). It is less detectable in newly metamorphosed frogs and may not be reliably detected in some species until two to three weeks after metamorphosis (Chestnut et al. 2008. Herpetol. Rev. 39:202–204). Few data are available regarding the fungal pathogens of embryos. Kiesecker and Blaustein (1997. Conserv. Biol. 11:214–220) reported *Saprolegnia ferax* on embryos of three anurans (*Bufo boreas*, *Rana cascadae*, and *Hyla regilla*) common to the Pacific Northwest, USA, and suggested that eggs in communal masses are highly susceptible to infection with *S. ferax*.

FIG. 1. Embryos of *Centrolene prosoblepon* infected by *Saprolegnia* sp.

Between November 2007 and March 2008, we found 20 different egg clutches of *Centrolene prosoblepon* infected by fungus (Fig. 1) near Falan, Tolima, Colombia (5.11666°N, 74.96666°W; WGS 84). We recorded between 25 and 35 dead embryos per clutch. We collected some of these clutches and transported them to the University of Tolima where the fungus was identified as *Saprolegnia* sp. Thus, mortality of embryos from fungal pathogens other than *B. dendrobatidis* may contribute to the global amphibian population decline.

We thank Oscar Cardozo and Gloria Palma for the identification of the fungus.

DENDROPSOPHUS MICROCEPHALUS (Yellow Cricket Tree Frog) **BEHAVIOR.** *Dendropsopus microcephalus* is a small nocturnal, yellowish frog that inhabits humid and dry lowlands along the Pacific slope of Costa Rica. It is generally found in open areas, perching in vegetation over water bodies (Savage 2002. The Amphibians and Reptiles of Costa Rica: A Herpetofauna Between Two Continents, Between Two Seas. University of Chicago Press, Chicago, Illinois. 934 pp.) Little is known about the ecology of dry-season aestivation for this and many other tropical anurans.

During the peak of the dry season during February 2004, we visited Palo Verde dry forest to observe the diurnal and nocturnal activity of *D. microcephalus* around a waterhole, and to observe behavior that might suggest a period of aestivation for this species. During the December–May dry season (Hartshorn 1983. *In* D. Janzen [ed.], Costa Rican Natural History, pp. 118–157. University of Chicago Press, Chicago, Illinois), the reduction of water bodies in this area leaves widely scattered pools that become very important for water-dependant organisms (Vaughan et al. 1997. Int. J. Trop. Biol. Cons. 45:1679–1682). We observed *D. microcephalus* perching between 1730 h and 0530 h, in aggregations of individuals in *Ardisia revoluta* shrubs around the waterhole. At all times the individuals stayed motionless and did not emit vocalizations or show conspicuous foraging activity. Between 0530 h and 1730 h, the individuals hid under the leaf-litter and remained motionless and silent as well. Such inactivity was constant throughout the peak of the dry season. Variation in water availability has been shown to induce behavioural responses in anurans to control evaporative water loss. This implies that amphibians respond to water shortage by adopting water-conserving postures (Pough et al. 1983. Ecology 64:244–252; Storey 2002. Comp. Biochem. Physiol. Part A 133:733–754). Hence, we suggest that *D. microcephalus* may be aestivating through the adoption of water-conserving postures around the waterhole, a limited resource during the driest months of the year.

Moreover, we observed that most individuals perched in the interior of the crowns of *A. revoluta*. We created categories to study the location of these perches to determine if individuals preferred perching in the interior of the crowns. We suggest that selecting perches that are less exposed in the vegetation might

serve as a strategy to avoid water loss. Our classification was based on two parameters: height and position of the perch in the crown of the shrub. Perch height was described in terms of three categories: Higher stratum (Hstr, the higher third of the crown), Middle stratum (Mstr, the intermediate third of the crown), and Lower stratum (Lstr, the lower third of the crown). Perch position was also placed in one of three categories: Periphery Zone (the external third of the crown, using the trunk as reference), Middle zone (the third that is found between the periphery and the internal part of the crown), and Inner zone (the third that is located in the internal part of the crown, next to the trunk). We expect that most individuals will select perches in the inner zone and the middle stratum.

Most individuals selected perches in the interior part (Middle stratum and Inner Zone) of the crown of *A. revoluta* (Higher stratum = 16 individuals, Middle stratum = 52 individuals, Lstr = 33 individuals; $\chi^2 = 19.26$, df = 1, $p < 0.05$) (Periphery zone = 6 individuals, Middle zone = 47 individuals, Inner zone = 48 individuals; $\chi^2 = 554$, df = 1, $p < 0.05$). Additionally, we used ANOVA to determine there was no relation between body size and perch selection, both in perch height ($F_{2.98} = 0.65$, $p = 0.52$) and perch position ($F_{2.98} = 0.56$, $p = 0.57$). This suggests that there is no evidence for size-mediated intraspecific competition for more protected perches, which may be because aestivation is characterized by a general lack of activity that could preclude active selection and defence of desirable perches.

We thank the OTS Ecology and Conservation course, 2004, where most data were collected and analyzed. We also thank James I. Watling for valuable comments on the manuscript.

Submitted by **BRANKO HILJE**, Biology Department, University of Puerto Rico, Río Piedras, P.O. Box 23360, San Juan, Puerto Rico, 00931-3360 (e-mail: bhilje@yahoo.com); and **MARIEL YGLESIAS**, Escuela de Ciencias Biológicas, Universidad Latina de Costa Rica, San Pedro de Montes de Oca, Costa Rica (e-mail: mariel_yglesias@yahoo.es).

ELEUTHERODACTYLUS ALTAMAZONICUS (NCN). **REPRODUCTION**. *Eleutherodactylus* species undergo direct development, forgoing an aquatic larval stage. It is generally assumed that species deposit eggs in trees within cavities or bromeliads, or on the ground amid moisture-retaining leaf litter or under rotting logs. However, records of oviposition by most species of *Eleutherodactylus* are rare.

On 26 May 2005, at 0830h we encountered a male (22.3 mm SVL, 0.66 g) and female (34.5 mm SVL, 2.03 g) *E. altamazonicus* in amplexus at the base of a large tree in primary, terra firma forest within Yasuní National Park in Ecuador (Provincia de Orellana). The pair was positioned over a small depression in the ground. The cavity was circular in shape, devoid of leaf litter, and roughly 3 cm in diameter and 1 cm deep. The pair was captured, placed together in a ziplock bag and taken back to the laboratory so measurements could be taken. Overnight, the female deposited 38 unpigmented eggs ca. 3.5 mm in diameter inside the bag. The eggs were returned to the depression from which the frogs were originally taken the next day. The study period ended 4 days after the pair was found. Therefore, we were not able to observe whether the eggs hatched. On 27 May, we encountered a second gravid *E. altamazonicus* female (32.1 mm SVL, 2.78 g) less than 100 m from the spot the first two individuals were encountered. These observations support previous suggestions that the beginning of the rainy season marks the onset of breeding in this species (Duellman 1978. Misc. Publ. Univ. Kansas, Mus. Nat. Hist. 65:1–352).

To our knowledge, only three clutches have been previously described for *E. altamazonicus.* The clutch size reported here is much greater and the eggs larger than those clutches (mean number of eggs in other reported clutches = 18.7, mean size = 2.8 mm) (Duellman 1978, *op. cit.*). This difference may be attributable to the large size of the female or potential geographic variation in reproduction in this species.

We thank the staff at Yasuni Research Station for logistical support and Amo Enomenga for field assistance. This observation was made during dissertation research supported by grants from the Conservation, Food and Health Foundation and the Louisiana Governor's Office of Environmental Education.

BRUCE WILLIAMSON**, Department of Biological Sciences, Louisiana State University, 107 Life Sciences Building, Baton Rouge, Louisiana 70803, USA, and Biological Dynamics of Forest Fragments Project, Instituto Nacional de Pesquisas da Amazônia and Smithsonian Tropical Research Institute, C.P. 478, Manaus, AM, Brazil (e-mail: jdeich1@lsu.edu).

HYLA AVIVOCA (Bird-voiced Treefrog). **DISTANCE FROM BREEDING SITE**. Essentially nothing is known regarding the distance *Hyla avivoca* moves from the breeding habitat after the breeding season. Smith (1961. Illinois Nat. Hist. Surv. Bull. 28:1–298) speculated that *H. avivoca* inhabits breeding sites year-round. Observations by Rossman (1960. Quart. J. Florida Acad. Sci. 22:207–225) and Redmer et al. (1999. Illinois Nat. Hist. Surv. Bull. 36:37–66) also suggest that *H. avivoca* remains at or near breeding sites outside the breeding season.

In contrast to these observations, I encountered two *H. avivoca* in Johnson County, Illinois, USA, away from breeding sites. I found an adult female on 8 May 2007 perched 1.2 m above the ground on a *Lonicera maackii* within a narrow strip of forest between a shrubby fallow field and a pasture (37.372778°N, 88.975°W). The female was 440 m west of the nearest *H. avivoca* breeding chorus located in June 2008 (37.3725°N, 88.97°W). On 20 May 2008, I heard a male *H. avivoca* diurnally vocalize from *Acer saccharinum*-dominated riparian forest (37.326003°N, 88.922953°W) 695 m from the nearest breeding site (37.332222°N, 88.921667°W).

The congeners, *H. versicolor* and *H. chrysoscelis* are known to make long-distance movements from breeding sites. Johnson et al. (2007. Biol. Cons. 140:250–258) followed a radio-tagged *H. versicolor* 271 m from its breeding site and Ritke et al. (1991. J. Herpetol. 25:123–125) documented movement of *H. chrysoscelis* up to 630 m between breeding sites. My observations indicate that *H. avivoca* is also capable of long-distance movements, suggesting that terrestrial habitat might provide essential resources outside the breeding season. Long-distance movements by *H. avivoca* might also allow exchange of individuals among disparate breeding choruses. This is especially important in southern Illinois where breeding locations of this state-threatened species are often separated by considerable distances.

I thank John Petzing and Floyd Scott for providing copies of difficult-to-procure literature, and the Illinois Endangered Species Protection Board for supporting Bird-Voiced Treefrog surveys.

Submitted by **JOHN G. PALIS**, P.O. Box 387, Jonesboro, Illinois, USA (e-mail: jpalis@yahoo.com).

HYLA SQUIRELLA (Squirrel Treefrog). **REPRODUCTION**. Clutch size is an important aspect of an organism's reproductive strategy and population biology. However, few studies report clutch sizes for *Hyla squirella*. Wright (1932. Frogs of the Okefinokee Swamp, Georgia. Macmillan Co., New York) reported clutch sizes of 942 and 972 eggs for two females allowed to oviposit in the laboratory. Subsequently, Livezey and Wright (1947. Am. Midl. Nat. 37:179–222) suggested clutches > 950 eggs. Martof et al. (1980. Amphibians and Reptiles of the Carolinas and Virginia. Univ. North Carolina Press, Chapel Hill. 264 pp.) speculate that clutches contain approximately 1000 eggs. The best estimate of *H. squirella* clutch size is from five females in Florida with a mean of 1059 (311 SD) eggs (Brugger 1984. Aspects of Reproduction in the Squirrel Treefrog. Unpubl. Master's thesis. University of Florida, Gainsville). Herein, I report the clutch sizes of four females from South Carolina.

I caught 10 female and 10 male *H. squirella* on 13 July 2005 from a small pond on the Savannah River Site in Barnwell County, South Carolina, USA. When captured, females were not in amplexus and all appeared to be gravid. Individuals were brought back to the Savannah River Ecology Laboratory (SREL) where males and females were paired in plastic containers (20.3 × 7.6 × 7.6 cm) with pond water. Five of the females oviposited within 36 hours of capture, but one clutch was excessively disturbed by the adults preventing an accurate count of the eggs. The four remaining clutches had a mean of 1511 eggs. This mean clutch size is considerably greater than those previously described. The snout-vent length (SVL) for three individuals was 32.0, 32.5, and 35.5 mm and they oviposited 1277, 1392, and 1592 eggs. One individual escaped prior to measurement. Although the sample size is small, clutch size appears positively correlated with female body size and warrants further investigation.

I thank Tom Luhring and Rachel Mahan for help catching animals and SREL for use of their facilities.

HYPSIBOAS ALBOMARGINATUS (White-edged Treefrog). **PREDATION.** Amphibians are frequently preyed upon by many types of predators, from carnivorous plants to large vertebrates. They provide a food source for many snake species and complement the diet of birds and mammals (Aucone and Card 2002. Herpetol. Rev. 33:48; Haddad et al. 2008. Atlantic Forest Amphibians. Neotropica, São Paulo, 243 pp.). *Hypsiboas albomarginatus* is widely distributed in Brazil, occurring in the Atlantic Forest from Rio Grande do Norte to Santa Catarina (Lutz 1973. Brazilian Species of *Hyla*. University of Texas, Austin). Reproduction occurs throughout the year in temporary ponds near the forest. During the day, individuals are observed sleeping in bromeliads or shrubs next to the breeding site or are found in trees at more distant sites. The Black Tufted-ear Marmoset, *Callithrix penicillata*, ranges from southeastern Maranhão and Piauí state, throughout most of Bahia, Minas Gerais, and Goiás state (Rylands et al. 1996. *In* Norconk et al. [eds.], Primates of the Atlantic Forest: Origin, Distributions, Endemism, and Communities, pp. 21–51. Plenum Press, New York). *Callithrix penicillata* is adapted to forest patches, gallery forests, scrub forests, and degraded forests in the Cerrado. This marmoset is omnivorous, feeding mainly on gum, fruits, arthropods, bird eggs, and small vertebrates. Herein, we report predation of an adult of *H. albomarginatus* by *C. penicillata* at Parque Estadual da Ilha Anchieta (23.5408889°S, 45.0658611°W; WGS 84), Ubatuba municipality, São Paulo state, southeastern Brazil. This monkey is an exotic species that was introduced in 1983 by the Fundação Parque Zoológico de São Paulo. Currently, *C. penicillata* occurs in high abundance on Ilha Anchieta and can severely affect the native fauna. In March 2007, an adult *C. penicillata* was observed eating an adult *H. albomarginatus* in a tree 2 m above ground. While holding the treefrog by its abdomen, the marmoset bit its head, and after eating the head, ate the forelimbs and the abdomen. The treefrog might have been sleeping when attacked. *Hypsiboas albomarginatus* has not been reported previously as prey for *C. penicillata*, since those animals did not occur in sympatry.

LEPTODACTYLUS OCELLATUS (Butter Frog). **BARN OWL PREDATION**. *Leptodactylus ocellatus* is a large frog characterized by black dots irregularly distributed over an olive green dorsum, which allows camouflage in the environment (Izecksohn and Carvalho-e-Silva 2001. Anfíbios do município do Rio de Janeiro. Editora UFRJ, Rio de Janeiro. 148 pp.). The species is widely distributed, occurring in most of South America east of the Andes (Frost 2007. Amphibian Species of the World: an Online Reference. Version 5.1; 10 Oct 2007. Electronic Database accessible at http://research.amnh.org/herpetology/amphibia/index.php. American Museum of Natural History, New York).

The stomach contents of a Barn Owl (*Tyto alba*, MBML 7380 [Museu de Biologia Prof. Mello Leitão]) were examined on 25 June 2008, and the almost intact legs and sacral region of *L. ocellatus* were found; only the forearms and head were digested. The Barn Owl was run over at km 53 of the Rodovia do Sol, a highway located at Municipality of Guarapari (20.6666667°S, 40.4975°W), State of Espírito Santo, Brazil, and was collected on 26 Oct 2007 at 2325 h. The Barn Owl is nocturnal and is found in a variety of habitats, including open areas and human modified environments (Sick 1999. Ornitologia Brasileira. Ed. Nova Fronteira, Rio de Janeiro, Brazil). Its diet is composed mainly of small mammals and invertebrates. Amphibians are also found, but in small quantities (Motta-Junior 2006. Rev. Brasil. Ornitol. 14[4]:359–377; Roda 2006. Rev. Brasil. Ornitol. 14[4]:449–452). This is the first report of *L. ocellatus* in the diet of *T. alba*. We

thank Rodosol S.A. for donation of material to the Museu Prof. Mello Leitão.

OOPHAGA PUMILIO (Poison Dart Frog). **NOCTURNAL ACTIVITY.** *Oophaga pumilio* is found over the leaf-litter of the Atlantic lowlands of Nicaragua, Costa Rica, and Panamá. It is usually seen in abandoned open areas and undisturbed forests throughout its range. This species has been characterized by its high abundance and diurnal habits by field studies mainly carried out at OTS, La Selva Biological Station in Sarapiquí, Costa Rica (Donnelly and Guyer 2004. Amphibians and Reptiles of La Selva, Costa Rica and the Caribbean Slope: A Comprehensive Guide. Univ. California Press, California, 367 pp.; Savage 2002. The Amphibians and Reptiles of Costa Rica: A Herpetofauna Between Two Continents, Between Two Seas. Univ. Chicago Press, Chicago, 934 pp.).Territoriality occurs in males of this species, as activity is constrained to an area that is defended from intruders (McVey et al. 1981. Copeia 1981[1]:1–8; Prohl 1997. Amphibia-Reptilia 18[4]:437–442.). Such defense has been associated with intraspecific competition related to resource availability (Donnelly 1989. Ecol. Monogr. 59[3]:207–221; Donnelly 1989. Oecologia 81[2]:212–218). Intrusions arise at different hours during the day, causing energetically expensive displays from resident frogs to repel the intruders (Gardner and Graves 2005. J. Herpetol. 39[2]:248–253). Male territories usually vary between 6 and 16 m^2 at La Selva Biological Station, and are maintained through vocalizations (Savage 2002, *op. cit.*).

The territorial behavior of *O. pumilio* includes vocalizations (Bunnell 1973. Copeia 1973[2]:273–284) and direct resident-intruder pinning, chasing, grappling, and tracking, among other agonistic behaviors. Postures such as body elevation using the forelimbs and statue behavior are also agonistic behaviors present in male-male interactions. Resident frogs usually remove the intruders, displaying greater dominance (Baugh and Forester 1994. Behavior 131[3–4]:207–224). Savage (2002, *op. cit.*) described a resident-intruder encounter, in which both males wrestle facing one another, and seizing each other's forelimbs. Generally the resident pins the intruder and the latter is released from the territory.

On 15 July 2003, we observed variations in the described behavior of *O. pumilio* at El Surá Trail in La Selva Biological Station (10.433°N, 83.983°S). We observed a nocturnal fight starting at 2008 h and finishing at 2143 h. The encounter started as both individuals were emitting vocalizations, an unexpected behavior since this species is regarded as diurnal. The encounter occurred as one individual (resident and intruder could not be identified) approached his opponent with several head bashes, making the latter fall on his back. This agonistic behavior has not been described previously. It consisted of both individuals facing each other a few centimeters away and abruptly colliding their heads without grasping each other's limbs. Subsequent to the attack, the offended individual bounced back and their heads collided again. A few minutes later, the individuals assumed a position that resembled an amplexus, eventually with one individual's pelvic region joined with the other's head. Both emitted vocalizations very different from those emitted against intruders during the day. Next, the individuals performed occasional leaps, in which one individual jumped from a perch to make the other fall on his back. The fight occurred intermittently as both males ceased the aggressions erratically and after a few minutes returned to the described behavior. At 2143h rain interrupted the encounter. After three minutes of inactivity, one individual emitted a loud vocalization from a 1m perch. His opponent, presumably the intruder, did not respond and abandoned the territory. All agonistic interactions occurred in a 1.5 × 1.5 m leaf-litter plot.

The described interactions show behavior variations from those described in earlier studies. Hence, there may be important variations in activity patterns, as well as in resident-intruder interactions during agonistic encounters.

Submitted by **BRANKO HILJE**, Biology Department, University of Puerto Rico, Río Piedras, P.O. Box 23360, San Juan, Puerto Rico, 00931-3360; (e-mail: bhilje@yahoo.com); and **MARIEL YGLESIAS**, Escuela de Ciencias Biológicas, Universidad Latina de Costa Rica, San Pedro de Montes de Oca, numero, Costa Rica; (e-mail: mariel_yglesias@yahoo.es).

PELOPHYLAX PEREZI (Iberian Green Frog). **POLYDACTYLY**. Teratological aberrations are common in Iberian amphibians, although data regarding this condition in *Pelophylax perezi* is scarce in natural populations (reviewed in García-París et al. 2004. Amphibia. Lissamphibia. *In* Ramos et al. [eds.], Fauna Ibérica Vo. 24. MNCN-CSIC, Madrid. 639 pp.). However, in introduced populations from the Canary Islands a large portion of the population shows morphological abnormality.

On 02 Feb 2006 an adult male *P. perezi* with a supernumerary toe was found in an eutrophic permanent pond from Central Spain (vicinity of Sieteiglesias de Tormes, province of Salamanca; 40.7282861°N, 5.6207972°W; 820 m elev.). The animal displayed another well-developed toe on the right hand (polydactyly; Meteyer 2005. Field Guide to Malformations of Frogs and Toads with Radiographic Interpretations. Biol. Sci. Rep. USGS/BRD/BSR-2000-0005. U.S. Geological Survey, Madison, Wisconsin. 18 pp.), between the fourth and fifth toe of a normal hand. After releasing, this frog was not recaptured in consecutive surveys.

Between 2001 and 2008 we monitored the amphibian population of this area, mainly in eutrophic ponds and recorded ca. 350 *P. perezi*. Only this one individual had any deformity (0.29% of the population) indicating this was an isolated case.

This malformation has not been previously described in this species. A high incidence of teratological cases was reported in an introduced population of the species in the Canary Islands (Luis and Báez 1987. Vieraea 17:295–296), however, polydactyly was not reported in any individuals.

We have no data to assess the cause of these malformations although limb abnormalities are mostly related to environmental pollution, genetic or developmental factors (also in synergy with the previous factor), parasites, or a failure in the regeneration processes (Álvarez et al. 1995. Arch. Environ. Cont. Tox. 28[3]:349–356; Blaustein and Johnson 2003. Front. Ecol. Environ. 1[2]:87–94; Meteyer 2005, *op. cit.*; Johnson et al. 2006. Ecology 87[9]:2227–2235).

Submitted by **PABLO GARCÍA** and **ISABEL MATEOS**, C/ Núñez de Zamora, 12-14, 1D, 30073 Salamanca, Spain (e-mail: garciap@usal.es).

RANA CLAMITANS **(**Green Frog). **COLORATION**. Herein I describe an unusual color pattern in a *Rana clamitans* that was found at the Edmund Niles Huyck Preserve in Rensselaerville, Albany County, New York, USA. Rather than the characteristic combination of brown and olive green, this individual displayed brilliant yellow across much of its dorsum. The abnormal frog (47.6 mm SVL) was found during Sept 2007, along a spring-fed stream (42.52545°N, 74.1594333°W). The front and back legs were more typical *R. clamitans* coloration, as was a large spot in the center of the animal's back (Fig. 1). Although most *R. clamitans* have a speckled venter, this individual had a creamy yellow underside, free of spots. Blue morphs of this species have been reported throughout New York State (Gibbs et al. 2007. Amphibians and Reptiles of New York State: Identification, Natural History, and Conservation. Oxford University Press, New York). Berns and Narayan (1990. J. Morphol. 132:169–180) determined that the blue morphs have reduced carotenoids and that xanthophores are absent or lacking carotenoid vesicles. The underlying mechanisms that led to the yellow coloration of the individual described here is unknown, as it is the first description of such coloration in New York State. It is unclear whether the morph seen here suffers from the loss or under expression of certain pigments.

I thank P. Ducey, A. Breisch, and J. Gibbs for their assistance in preparing this note.

RANA DRAYTONII **(**California Red-legged Frog). **PREY**. On 19 June 2004 in a large cattle pond in Morgan Territory Regional Preserve, Alameda County, California, USA (37.82°N, 121.79°W), I observed an adult *Rana draytonii* (ca. 95 mm SVL) eat a Western Toad (*Bufo boreas*) tadpole. It was unclear if the frog simply snapped at the motion of the tadpole which had swam underneath the frog's chin, or had deliberately sought out the tadpole.

I returned to the pond five days later and observed 10 adult *R draytonii* sitting in the shallows at the edge of the pond in an area with large numbers of *B. boreas* tadpoles. In 30 min I observed three instances of *R. draytonii* eating *B. boreas* tadpoles. One adult frog was observed twice in that time eating toad tadpoles. A second adult frog was observed jumping forward into an aggregation of tadpoles, using its front feet to help push tadpoles into its mouth. The frog paused with the tail of a toad tadpole hanging out of its mouth, and then swallowed. There was no indication in any of these instances that the tadpoles were in any way unpalatable or distasteful. Since *R. draytonii* and *B. boreas* often share ponds, predation by *R. draytonii* on bufonid tadpoles may not be an uncommon event. Because *R. draytonii* is only recently recognized as a full species (Schaffer et al. 2004. Mol. Ecol. 13:2667–2677) there is limited dietary information available for the species (Hayes and Tennant 1985. Southwest. Nat. 30:601–605; Hayes and Jennings 2006. Herpetol. Rev. 37:449).

This report points to a mystery. Given that ranid frogs and *Bufo* often share the same ponds, and *Bufo* tadpoles are potentially an abundant source of food at certain times, why are there not more reports of ranid frogs eating *Bufo* tadpoles? Bufonid tadpoles contain skin chemicals that make them unpalatable to at least some predators (Brodie et al. 1978. Herpetologica 43:369–373). However, a recent review of tadpole palatability experiments concluded that *Bufo* tadpoles are rarely unpalatable to predators, and no more so than other families of anurans (Gunzburger and Travis 2005. J. Herpetol. 39:547–571). A review of the predation sections of the natural history accounts for North American *Bufo* in Lannoo [ed.] (2005. Amphibian Declines: Conservation Status of United States Species. Univ. California Press, Berkeley. 1094 pp.) found only one report of ranid frog predation on *Bufo* tadpoles, that of Mountain Yellow-legged Frog (*Rana muscosa*) consuming Yosemite Toad (*Bufo canorus*) tadpoles (Mullally 1953. Copeia 1953[3]:182–183), and only a single other report of an anuran predator on *Bufo* tadpoles —that of Great Plains Toad tadpoles (*Bufo cognatus)* being eaten by Mexican Spadefoot tadpoles (*Spea multiplicata*) (Bragg 1940 Am. Nat. 74:322–349). Pearl and Hayes (2002 Am. Midl. Nat. 147:145–152) observation of Oregon Spotted Frogs (*R. pretiosa*) frequently eating recently metamorphosed *B. boreas* appears to be the only report in the literature of an anuran predator on *B. boreas*.

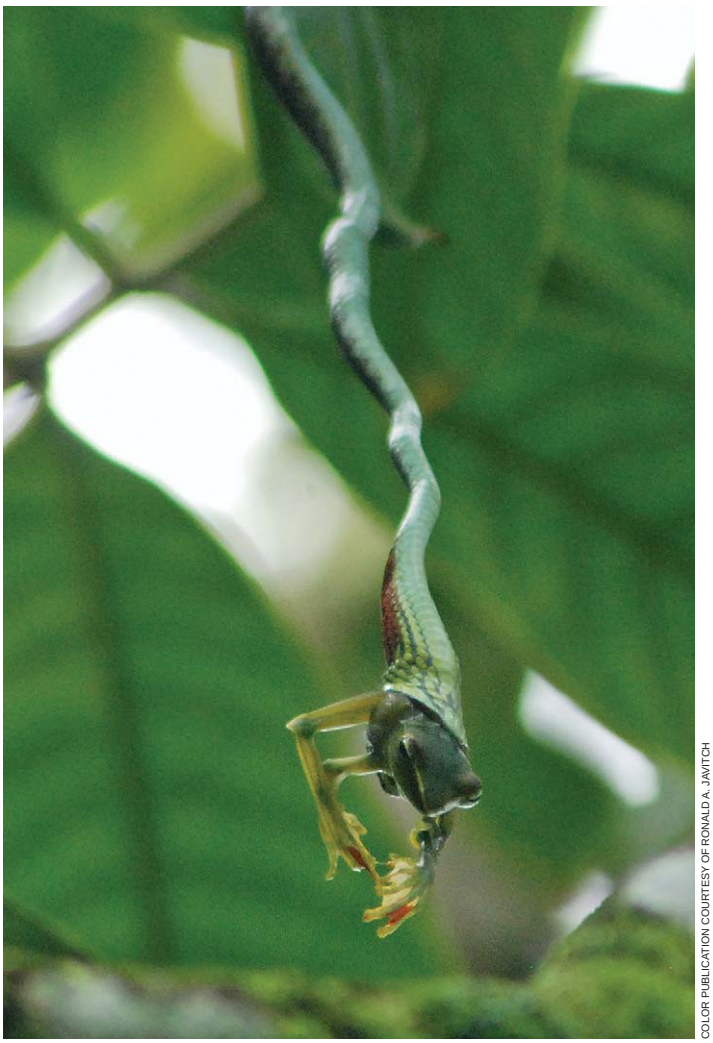
RANA PICTURATA (Yellow-spotted Frog). **PREDATION**. Among invertebrates, spiders are one of the most important predators of amphibians (Wells 2007. The Ecology and Behavior of Amphibians. Univ. Chicago Press, Chicago, Illinois. 647 pp.). Predation of spiders on amphibians has often been reported (Duryea

COLOR PUBLICATION COURTESY OF RONALD A. JAVITCH

FIG. 1. Right: A dead adult male *Rana picturata* wrapped up by spider's thread. Left: Huntsman spider (*Heteropoda* sp.) feeding on *Rana picturata*.

et al. 2008. Herpetol. Rev. 39:209–210), but records from Southeast Asia are few, probably due to paucity of natural history surveys in the region. We observed a huntsman spider (*Heteropoda* sp.) preying on an adult male *Rana picturata* (SVL 39.1 mm) in Takah Selow Waterfall, Selai, in the Endau-Rompin National Park, Johor, Peninsular Malaysia (2.4427778°N, 103.2419444°E, 111 m elev.) at 2215 h on 2 Aug 2008. *Rana picturata* is common in this area, and males were found calling perched on stones, fallen wood, or leaves of shrubs close to stream edges. The frog was found dead, wrapped up in the spider's thread (Fig. 1), on the side of vertical dead trunk (3.5 cm diam.). It was located ca. 1.5 m above the surface of a rocky stream. The spider ran away when disturbed, leaving the dead frog behind. We stopped observation to continue our amphibian survey, but when we returned the spider was found feeding on the frog (Fig. 1). We collected the spider and the frog for further examination. Like members of other genera in the family Heteropodidae, *Heteropoda* do not build webs and are ambush predators, killing their prey by injection of venom. The other genus within the family reported to have preyed upon amphibians is *Olios* (giant crab spider) from Puerto Rico (Formanowicz et al. 1981. Herpetologica 37[3]:125–129). The spider was retained by H. Ono, Natural Science Museum, Tokyo, for identification.



Field work was conducted with permission of the Economical Planning Unit (EPU), and financed by the Japan Society for the Promotion of Science (JSPS: No. 20405013) and by Universiti Kebangsaan Malaysia to MM. We are grateful to Yong Hoi Sen (University of Malaya) and H. Ono for help in identification of the spider.

RHACOPHORUS DULITENSIS (Jade Tree Frog). **PREDATION.** Tree frogs of the genus *Rhacophorus* are distributed from India to Japan, the Indomalayan archipelago, and the Philippines. Due to their arboreal lifestyle, most species are seldom encountered and there is little information available regarding their natural history. *Rhacophorus dulitensis* is endemic to Borneo (Harvey et al. 2002. Herpetol. Monogr. 16:46–92), where it occurs in primary and old secondary forests. Herein, I report predation on this species by the tree snake, Kopstein's Bronzeback (*Dendrelaphis kopsteini*).

On 12 Dec 2007 between 1330 and 1355 h I observed an adult *R. dulitensis* being preyed upon by a subadult *D. kopsteini* (total length ca. 70 cm) in the top of a medium-sized tree, about seven meters above the ground in the alluvial forest near the headquarters of Gunung Mulu National Park, Sarawak, East Malaysia (Borneo). When the observation started the snake had already grabbed the frog by one of its hind limbs. After a few minutes it maneuvered the frog in its mouth with chewing motions, until the posterior part of the frog's trunk was between its jaws. Then it began to devour the frog (Fig. 1). The frog remained alive at least until it was completely swallowed.

I thank the Sarawak Forest Department for permission to conduct research in Gunung Mulu National Park. Field work was supported by a grant from the German Academic Exchange Service

RHACOPHORUS GAUNI (Short-nosed Tree Frog). **EGG MORTALITY.** To prevent predation by aquatic predators, many frog species do not place their eggs directly in the water but deposit them in foam nests either floating on the water's surface or attached to vegetation above the water. Outside the water, however, frog eggs are exposed to a large number of invertebrate and vertebrate predators (Wells 2007. The Ecology and Behavior of Amphibians. University of Chicago Press, Chicago and London. 1148 pp.). Fly larvae have been reported to be very destructive on these foam nests. Investigations in Central and South America, Australia, and Taiwan have shown that in foam nests of particular frog species the prevalence of fly larvae infestation and the mortality caused by it can be very high (Wells 2007, *op. cit.*). Herein I report predation by fly larvae on the eggs of *Rhacophorus gauni*. All Bornean members of the genus *Rhacophorus* lay their eggs in foam nests attached to leaves overhanging water (Malkmus et al. 2002. Amphibians and Reptiles of Mount Kinabalu [North Borneo]. Koeltz Scientific Books, Königstein. 424 pp.), apart from *R. kajau* which attaches its eggs directly to leaves without producing a foam nest (pers. obs.). So far, there have been no reports of predation on eggs of Bornean *Rhacophorus*.

Observations were made in Gunung Mulu National Park, Sarawak, East Malaysia (Borneo). Adult *R. gauni* were found in abundance along sections of two rivers, Sungai Melinau near Camp Five and Sungai Melinau Paku near Deer Cave. Frogs were sitting on leaves 2–6 m above ground. Calling males and recently produced foam nests were regularly observed from October 2007 to January 2008, indicating that breeding is prolonged and perhaps occurs throughout the year. Two foam nests sampled on 7 Oct 2007 at Sungai Melinau Paku and on 4 Dec 2007 at Sungai Melinau contained fully developed tadpoles, numbering 9 and 13. There were no signs of infestation by parasites or predators. On 7 Jan 2008, I found two foam nests at the Sungai Melinau Paku site. In both, fly larvae (Diptera) were visible from the outside. Closer examination revealed that the nests were heavily infested with fly larvae (Fig. 1). No living frog embryos, but only the remains of undeveloped eggs were found within the nests. According to these preliminary observations, the prevalence of fly larvae infestation seems to be moderate in foam nests of *R. gauni*. Mortality of eggs, however, appears to be absolute in infested nests.

FIG. 1. Foam nest of *Rhacophorus gauni*, heavily infested with fly larvae.

I thank the Sarawak Forest Department for permission to conduct research in Gunung Mulu National Park. Field work was supported by a grant from the German Academic Exchange Service (DAAD).

CROCODYLIA — CROCODILIANS

CROCODYLUS SIAMENSIS (Siamese Crocodile). **DIET.** Few published observations are available on the diet, feeding, or predatory habits of *Crocodylus siamensis*, among the most critically endangered and least known of crocodilians (Ross [ed.] 1998. Crocodiles. Status Survey and Conservation Action Plan. 2nd ed. IUCN, Gland. 96 pp.). A study of 291 fecal samples from Cambodia provides the only published dietary data for *C. siamensis*, and which recorded the remains of snakes (in 35.7% of samples), fish (31.6%), insects (18.6%), mammals (11.0%), and birds (5.2%), suggesting *C. siamensis* is a generalist feeder similar to many other *Crocodylus* (Daltry et al. 2003. Status of the Siamese Crocodile in the Central and Southern Cardamom Mountains, Cambodia. Findings of Recent 'Kropeu Phnom' Surveys. FFI/Department of Forestry and Wildlife, Phnom Penh; Simpson and Han 2004. *In* Proc. 17th Working Meeting Crocodile Specialist Group. pp. 110–120. IUCN, Gland). Dietary studies based only on feces present a biased view of crocodilian diet due to the variable digestibility of prey (keratinous and chitinous substances are commonly recorded in feces while soft-bodied prey [e.g., frogs] are absent) and of digestion times among differently sized crocodiles, which prevent analysis of food preferences and the contribution of individual prey species to total mass of food consumed (Fisher 1981. Paleobiology 7:262–275; Shoop and Ruckdeschel 1990. Am. Midl. Nat. 124:407–412; Webb et al. 1991. J. Herpetol. 25:462–473; Webb et al. 1982. Aust. J. Zool. 30:877–899; Santos et al. 1996. The Herpetological J. 6: 111-117). Yet in the absence of studies involving live wild crocodiles, fecal samples provide preliminary insight on dietary habits, and for *C. siamensis*, are particularly useful because extant populations are so depleted that wild individuals are rarely observed or caught.

Here I report on the contents of seven *C. siamensis* fecal samples collected during crocodile surveys in the Lao People's Democratic Republic (hereafter 'Laos') (Bezuijen et al. 2006. Preliminary status review of the Siamese Crocodile [*Crocodylus siamensis* Schneider, 1801] [Reptilia: Crocodylia] in the Lao People's Democratic Republic. LARReC/WCS/MWBP, Vientiane. 114 pp.; Bezuijen et al. 2006. Strengthening Siamese crocodile conservation in Lao PDR. Crocodile Specialist Group Newsletter 25:10–11).

Crocodylus siamensis feces were collected in the dry season at three permanent, freshwater lakes (elevations 120–150 m elev.) with extensive macrophyte growth: Bung Pulone Lake (14.70888°N, 106.46555°E), Attapu Province, 13 April 2005 (N = 5 samples), and Kout Mark Peo Lake (16.35250°N, 105.22083°E), 12 March 2005 (N = 1) and Xe Lat Nyai Lake (16.44722°N, 105.19277°E), 20 September 2006 (N = 1), Savannakhet Province. These lakes are located on floodplains of the Mekong River and are subject to extensive seasonal changes in water level. Six fecal samples were located along seasonally-exposed lake margins and one, at Kout Mark Peo Lake, was on a mat of floating vegetation. Fecal diameter (widest point of bolus) ranged from 30–45 mm (Table 1), representing a range of differently sized crocodiles. Feces were initially dry and hard, and were subsequently soaked in water. They were then broken apart and observed under a dissecting microscope.

Six of seven samples contained prey items; the sample from Xe Lat Nyai Lake contained no prey remains. Prey items and their frequency of occurrence were: mammal (86%, N = 6 samples), fish (71%, N = 5), and snake (57%, N = 4) (Table 1). The chitinous fragments of coleopteran elytra (beetle forewings) were present in four samples. A small amount of plant matter and four sand grains <1 mm diameter were found in six and one sample respectively. It is unclear whether the insects were deliberately caught as prey; the plant matter and sand were probably secondarily ingested.

No prey items could be identified to species level. Bone fragments present in one sample, including one incisor (3 mm length) and intact vertebrae (3–4 mm diameter excluding transverse processes) were identified as those of a rodent (Muridae). To identify the mammalian hair present in six samples, mounted slide cross-sections and longitudinal-sections from 10–15 hairs in each sample were prepared by H. Brunner and examined under ×470 magnification, following Brunner and Coman (1974. The Identification of Mammalian Hair. Inkata Press, Melbourne. 173 pp.), and compared against a hair reference database (Ecobyte Pty Ltd et al. 2002. Hair ID vers. 1.00. CSIRO Publishing, Collingwood, Victoria). No commercial hair reference database is available for Southeast Asia and the current database, although developed principally for Australian mammals, was used because it includes datasets for several orders of Asian mammals. All hair samples were from the same prey species, a rodent (not *Rattus*), and possessed the following features: a two-tiered layer of relatively long (15–20 mm), stiff, primary guard-hairs, brown-black and tinged red, with a cross-sectional diameter of 175–200 μm, and shorter, finer, grey under-hairs. These hair features, the size of bone fragments (presumably from the same prey species), and the habitat where feces were located, suggests a medium-sized, ubiquitous rodent common in lowland wetlands of the Mekong Basin, such as *Bandicota indica* (Greater Bandicoot Rat) (Francis 2008. A Field Guide to the Mammals of Thailand and South-East Asia. Asia Books Co., Ltd, Bangkok. 392 pp.).

Fish remains comprised the scales of at least two species (Table 1), which, based on scale size and shape, and wetland habitat, were possibly *Channa* spp., one of few fish genera able to tolerate dry-season conditions of these floodplain lakes (Hill 1995. Nat. Hist. Bull. Siam Soc. 43: 263–288; Kottelat 2001. Fishes of Laos. WHT Publications [Pte] Ltd., Colombo. 198 pp.). Snake remains comprised dorsal and ventral scales.

In addition to data derived from fecal samples, on 13 March 2005 at 2130 h, I briefly observed a wild hatchling *C. siamensis* catching insects at the water surface near the margin of Kout Mark Peo Lake.

TABLE 1. Contents of seven *Crocodylus siamensis* fecal samples from Laos.

Site	Dung size (mm)	Contents
Bung Pulone Lake	85 × 37	Mammal hair; fish scales (sp. A–scales transparent, thin, 3–5 mm diameter)
Bung Pulone Lake	95 × 45	Mammal hair; fish scales (sp. A); snake scales; insect chitin fragments; plant matter
Bung Pulone Lake	125 × 30	Mammal hair; fish scales (sp. A); snake scales; insect chitin fragments; plant matter
Bung Pulone Lake	175 × 40	Mammal hair; fish scales (sp. A+B–scales brown, opaque, thick, 6 mm diameter); plant matter
Bung Pulone Lake	150 × 45	Mammal hair, bone (incisor, vertebrae, other fragments); fish scales (sp. B); snake scales; insect chitin fragments; plant matter
Kout Mark Peo Lake	180 × 43	Mammal hair; snake scales; insect chitin fragments; plant matter; sand particles
Xe Lat Nyai Lake	130 × 40	Plant matter

The small sample size of these data precludes comparison with other studies, although the identified remains indicate a broad diet, and the high frequency of occurrence of mammalian remains compared with Cambodian samples may be of note. Further collection and analysis of *C. siamensis* fecal samples from Laos, as well as examination of the fresh stomach contents of wild-caught individuals, would be required to ascertain any seasonal differences in diet or prey preference between *C. siamensis* of different age, size, or geographic distribution.

Fecal samples were collected during crocodile conservation activities by the Laos Department of Forestry/Wildlife Conservation Society, and Laos Department of Livestock and Fisheries/WWF Laos, respectively. I am grateful to Hans Brunner for preparing and analyzing hair samples. Roger Mollot gave advice on fish identification, and Jennifer C. Daltry, Jackson Shedd, Boyd Simpson, and John B. Thorbjarnarson provided critical comments which improved the draft manuscript.

TESTUDINES — TURTLES

APALONE MUTICA (Smooth Softshell). **PREDATION.** Around 1300 h on 2 July 2006 on the Buffalo River in Marion County, Arkansas, USA, we observed an adult *Apalone mutica*, ca. 30 cm in carapace length, being attacked by a group of otters (*Lontra canadensis*). This event occurred in riffle habitat about one meter deep below debris from two fallen trees. We were standing in the stream about 3–4 m from the attack, but our presence did not appear to disrupt the behavior of the animals. The turtle was clearly

alive and trying to escape from 2–3 otters that were biting its shell and continually pulling it below the surface of the water. The turtle appeared disoriented and exhausted. The otters in the stream were also vocally communicating with 1–2 otters that were on the bank, at least one of which did not appear to be an adult. After observing the encounter for about five minutes, the turtle was carried upstream by the otters, which had apparently subdued it.

National, Springfield, Missouri 65897, USA (e-mail: AdamCrane@MissouriState.edu); and **BEN PARNELL**, Missouri Department of Conservation, 783 Thunder Mountain Road, Camdenton, Missouri 65020, USA (e-mail: Todd.Parnell@mdc.mo.gov.edu).

CHELYDRA SERPENTINA (Snapping Turtle). **CLEANING SYMBIOSIS**. The removal of ectoparasites, necrotic tissue, and epibionts from marine turtles by reef fishes (Grossman et al. 2006. Chelon. Conserv. Biol. 5:284–288; Losey et al. 1994. Copeia 1994:684–690) and invertebrates (Davenport 1994. J. Mar. Biol. Assoc. U.K. 74:735–737) has been well documented. Cleaning symbioses involving freshwater turtles are also known (Moll and Moll 2004. The Ecology, Exploitation, and Conservation of River Turtles. Oxford Univ. Press, New York. 393 pp.); however, observations of these interactions in freshwater species are rare in the literature compared with those of marine turtles. Here, I report an apparent episode of mutualistic cleaning between a *Chelydra serpentina* and Bluegill Sunfish (*Lepomis macrochirus*).

On 06 June 2007 at 1830 h, I observed a *C. serpentina* (ca. 20 cm SCL) in shallow water along the shoreline (39.33882°N, 82.34693°W; WGS 84) of Lake Hope at Lake Hope State Park, Vinton County, Ohio, USA. When first encountered, the turtle was floating just below the surface in open water. The limbs and tail of the turtle were extended out and downwards from the body and its neck was fully extended horizontally. A school of ca. 9 *L. macrochirus* surrounded the turtle. As the fish slowly swam around the *C. serpentina*, they frequently oriented towards the turtle and approached to within 2–3 cm of it. The fish appeared to inspect the *C. serpentina* and individuals were twice seen nipping at the turtle. The fish primarily concentrated on the posterior and inguinal regions of the turtle; however, they would occasionally swim to the anterior of the carapace and axillary areas. Interactions between the turtle and fish were observed and photographed for ca. 30 min before the *C. serpentina* became aware of my presence and submerged. During the observation period, the turtle did not appear bothered by the actions of the fish; it made no movements except to raise its head to breathe and slowly turn to examine its surroundings. The *C. serpentina* did not attempt to strike at the fish despite the fact that several individuals ventured close to the turtle's head.

Facultative cleaning behavior is not unusual in *L. macrochirus* and other centrachid fishes (Powell 1984. Copeia 1984:996–998; Spall 1970. Trans. Amer. Fish. Soc. 99:599–600; Sulak 1975. Anim. Behav. 23:331–334). Bluegills have previously been reported to bite at resting turtles (Kaufmann 1991. Herpetol. Rev. 22:98; Powell, *op. cit.*). However, to my knowledge, this observation represents the first report of a turtle that appeared to encourage attention from *L. macrochirus*. The neck extension and behavior of the *C. serpentina* were similar to the posture and movements described by Kaufmann (*op. cit.*) for *Glyptemys* (= *Clemmys*) *insculpta* being cleaned by Blacknose Dace (*Rhinicthys atratulus*). Snapping turtles are frequent hosts for leeches (Brooks et al. 1990. J. Parasitol. 76:190–195; McCoy et al. 2007. Southeast. Nat. 6:191–202) and epizoophytic algae (Edgreen et al. 1953. Ecology 34:733–740). Both items appear in the diet of sunfish (Etnier 1971. Trans. Amer. Fish. Soc. 100:124–128), suggesting a possible route for opportunistic cleaning symbiosis to develop between these species. Given the widely overlapping distributions of *C. serpentina* and *L. macrochirus*, this relationship may be common but previously unrecognized.

Submitted by **JEFFREY E. DAWSON**, Reptiles/Shores Region, Columbus Zoo and Aquarium, 4850 W. Powell Road, P. O. Box 400, Powell, Ohio 43065, USA; e-mail: jeff.dawson@columbuszoo.org.

CHELYDRA SERPENTINA (Common Snapping Turtle). **SURVIVAL AFTER INJURY.** We here report an adult *Chelydra serpentina* from Wethersfield Cove, Wethersfield, Connecticut, USA, missing most of its lower jaw (Fig. 1). This old injury to the jaw would presumably disable both the suction-feeding apparatus (by reducing flow speed during strike and increasing backflow during buccopharyngeal compression) described for this species (Lauder and Prendergast 1992. J. Exp. Biol. 164:55–78) and eliminate bite force (Herrel et al. 2002. J. Evol. Biol. 15:1083). Yet this turtle weighed 17.5 kg and had a carapace length of 44.5 cm; visual examination showed ample fat deposits indicating that this turtle was in good condition despite its injury. The turtle was apparently able to heal and grow after the loss of the lower jaw, thus compensating for the lack of normal biting and prey-handling behaviors.

FIG. 1. Male Common Snapping Turtle missing most of its lower jaw, Wethersfield Cove, Hartford, Connecticut, USA (44.5 cm carapace length, 17.5 kg). This animal apparently healed and grew without being able to suction feed or produce bite force.

Submitted by **TOBIAS LANDBERG** (e-mail: tobias.landberg@huskymail.uconn.edu), and **COLIN J. CARLSON**, Ecology & Evolutionary Biology, University of Connecticut, Storrs, Connecticut, USA; **KYLER ABERNATHY**, The National Geographic Society, Washington D.C., USA; **CHRISTIAN LUGINBUHL**, Luginbuhl Foundation, Tolland, Connecticut, USA; **PAUL GEMME**, Our Piece of the Pie, Hartford, Connecticut, USA; and **CRAIG MERGINS**, Riverfront Recapture, Hartford, Connecticut, USA.

GLYPTEMYS INSCULPTA (Wood Turtle). **MAXIMUM ADULT SIZE.** On 21 June 2009, we captured an adult male *Glyptemys insculpta* in a tributary of the Kennebec River in Somerset County, Maine, USA. This turtle had been captured and radiotracked as a subadult by BWC in 1998 (Compton 1999. Ecology and Conservation of the Wood Turtle [*Clemmys insculpta*] in Maine. Unpubl. M.S. thesis, Univ. of Maine, Orono). Age estimates from plastral annuli in 1998 and 2009 indicate that the animal was ca. 25 years old upon recapture in 2009. Carapace and plastron dimensions were measured using a 12-inch dial caliper and the animal was subsequently released at the capture location. Shell dimensions (to nearest 0.1 mm) were as follows: straightline carapace length (SCL)(from cranial end of nuchal scute to caudal end of seam between 12th marginal scutes): 240.0; maximum carapace length (MCL)(from cranial edge of 1st or 2nd marginal scute to caudal end of 12th marginal scute): 251.0; straightline plastron length (from cranial end of seam between gular scutes to caudal end of seam between anal scutes): 200.9; maximum plastron length (from cranial edge of left gular scute to caudal edge left anal scute): 220.2; plastron width (at seam between humeral and pectoral scutes): 89.4; carapace width (at 8th marginal scutes): 180.3. Body mass was 1895 g. This turtle is markedly larger than the ten adult male *G. insculpta* measured at this site by Compton (1999) (MCL median = 215.0 mm; MCL max = 232.5 mm) and 48 adult male *G. insculpta* from New Hampshire (MCL median = 190.8; MCL max = 208.8) and 198 adult male *G. insculpta* from Massachusetts (MCL median = 188.5; MCL max = 213.9) measured by MTJ (Jones 2009. Spatial Ecology, Population Structure, and Conservation of the Wood Turtle in Central New England. Unpubl. Ph.D. dissertation, Univ. of Massachusetts, Amherst). The animal's current shell dimensions appear to be larger than most or all reported measurements from across the range of *G. insculpta*. Saumure (1992. Herpetol. Rev. 23:116) reported two extremely large males from Pontiac Co., Québec, with carapace lengths of 238.0 and 234.5 mm. In a review of the status of Wood Turtles in Québec, where the species appears to attain a relatively large adult size, Galois and Bonin (1999. Rapport sur la situation de la tortue des bois (*Clemmys insculpta*) au Québec. Faune et Parcs Québec, Direction de la faune et des habitats, Québec) reported a maximum carapace length of 244 mm. The authors did not indicate whether this represented SCL or MCL in the sense outlined above.

This research was conducted under Wildlife Scientific Collection Permit #2009-278 from the State of Maine Department of Inland Fisheries and Wildlife.

COMPTON**, Department of Natural Resources Conservation, University of Massachusetts, Amherst, Massachusetts 01003, USA (e-mail: bcompton@nrc.umass.edu).

KINOSTERNON SUBRUBRUM (Eastern Mud Turtle). **MASS MOVEMENT AND MORTALITY**. About 0930 h on 25 April 2009, after a night of heavy rain, we began a survey of paved secondary roads south of Winnie in Chambers County, Texas, USA looking for shorebirds (Scolopacidae, etc.) in rice fields. We drove west on St. Rd. 1985 and then north to and back east on St. Rd. 65, parallel roads about 13 km apart, and beginning and ending on the north-south running St. Rd. 124.

We found few shorebirds, but instead encountered an extraordinary mass movement and associated road mortality of the mud turtle *Kinosternon subrubrum.* Especially on the eastern ends of both roads, and mostly on 1985, we saw hundreds of dead and smashed turtles, some moribund, and perhaps 20 or so more trekking across the roads. The movement we saw of live turtles was entirely north to south across the east-west running roads; we noticed little, if any similar mortality on Rd. 124.

We estimated a very conservative 300 dead and dying mud turtles; the total was possibly much higher than this. Even crude quantification was difficult because of heavy local farm traffic, but at times it was possible to count 20–30 dead turtles in a stretch of 20 m; the circumstances also prevented us from examining specimens and determining sex ratios.

This was a monospecific event, as we otherwise noted only two large cooters (*Pseudemys* sp.), one living and one dead; we also saw a snake (*Nerodia* sp.) that successfully crossed the road before we could turn around to identify it. We are familiar with similar mass movements (and mortality) following rains by toads, frogs, and salamanders, but saw none of these in this instance, and we had not previously witnessed such a movement by turtles. Reports of other significant (though much smaller) movements of *K. subrubrum* seem associated with drying habitat (e.g., Strecker and Gibbons et al. *In* Ernst et al. 1994. Turtles of the United States and Canada, p. 172. Smithsonian Inst. Press, Washington, DC).

Interpretation of the phenomenon we observed was confounded by the inundation of thousands of the surrounding hectares in 2–3 m of salt water during the storm surge of Hurricane Ike on 13 September 2008. We overheard residents talking of flooding fields to leach the salt before rice could be planted. Nevertheless the movement we saw was coincident with a local deluge of rain. The nearest official rain gauge in Beaumont, Texas, 38 km to the east, recorded only 0.52 inches of rain 24–25 April (Donna Work, Texas Forest Service, pers. comm., 20 May 2009), but around Winnie the total was manifestly much more that that; we heard local commentary on the extraordinary rainfall the night of 24–25 April and saw abundant evidence in flooded fields and residential yards, and water overflowing drainage ditches onto the roads, so the local rainfall must have been considerable.

We are grateful to D. Bruce Means and Lora L. Smith for helpful suggestions.

PODOCNEMIS EXPANSA (Giant South American River Turtle). **PRE-NESTING BASKING BEHAVIOR**. *Podocnemis expansa* is a freshwater pleurodiran turtle native to the Amazon basin. This species was historically common and could be observed basking and nesting in large numbers, but this is now a rare occurrence over most of the Amazon (Rueda-Almonacid et al. 2007. Las Tortugas y los Crocodilianos de los Países Andinos del Trópico. Serie de Guias Tropicales de Campo nº 6. Conservación Internacional. Editora Panamericana, Formas y Impresos. Bogotá, Colombia, 538 pp.). In this species, basking behavior is reportedly restricted to the period just prior to, or during, nesting (although RCV has one record of a juvenile ca. 8 cm in carapace length basking on a log in Anavilhanas National Park, Amazonas Brazil, 23 February 1989). In many areas of the Amazon, pre-nesting basking is no longer observed, a behavioral change possibly in response to human predation (Vogt 2008. Tartarugas da Amazônia. Grafica Biblos, Lima, Peru. 104 pp.) However, on the Trombetas River, Pará, Brazil, basking behavior prior to nesting is still observed, perhaps due to the efforts of the Brazilian Environmental National Institute (IBAMA) to protect the nesting beaches against human predation.

Here we report basking observations during the reproductive season of 2008, from 30 September to 2 November (230 h of observations) on the Praia do Jacaré (1.530494ºS, 55.473148ºW; WGS84). The average number of turtles basking per day was 106 (min. 7 – max. 295; SD = 87). The turtles started basking on 30 September in small numbers (7–15), increasing over subsequent days until they reached a peak on 21 October (295 turtles). At this point the nesting season began (21 October) and the average number of turtles basking daily dropped to 51, and continued to decrease until basking ceased on 3 November. During the basking period, the turtles aggregated in large groups, including the turtles on the beach as well as those in the water. Basking behavior in this circumstance may increase the metabolic rate of the female, accelerating egg development and ovulation (Vogt 1980. Tulane Stud. Zool. Bot. 22:17–48). Despite living in warm waters (mean water temperature = 30.2°C [RCV, unpubl. data] from 3538 temperature recordings in the field in Trombetas Reserve from Nov–September), the physiological advantages of basking to the turtles apparently outweigh the risks involved from the increased exposure to predation.

SQUAMATA — LIZARDS

AMEIVA AMEIVA (Giant Ameiva). **PREDATION.** Despite its broad distribution in South America (Vitt and Colli 1994. Can. J. Zool. 72:1986–2008) and various aspects of natural history having been described (Colli 1991. Copeia 1991:1002–1012), few data exist on the predators of *Ameiva ameiva* (Martins and Oliveira 1998. Herpetol. Nat. Hist. 6:78–150). Hence, we add to the limited data on *A. ameiva* predators with an observation of predation by a Pearl Kite (*Gampsonyix swainsonii*).

On 27 April 2008 at ca. 1200 h, while conducting an ornithological survey as a part of the Environmental Impact Study of the Foz do Apiacás Hydroelectric Power Plant in Mato Grosso State, Brazil, we collected an adult *G. swainsonii* with a pressure gun from a grassland area of Paranaíta, Mato Grosso (57.1092°W, 9.4155°S, datum: SAD69; elev. 701 m); dissection revealed two juveniles *A. ameiva* (40.82 mm and 34.93 mm, SVL) in the stomach. The grasslands were surrounded by rain forest dominated by Babaçu Palms (*Orbignya oleifera*).

Gampsonyix swainsonii are known to prey on insects, birds and lizards (Sick 2001. Ornitologia Brasileira. Editora Nova Fronteira. Rio de Janeiro, Brazil. 862 pp.), but to our knowledge, none of the lizards recorded as prey were identified to species.

The *G. swainsonii* specimen (JB 395 – collection license 10698-1/IBAMA) (length: 22.5 cm) and its stomach contents were deposited in Laboratório de Ornitologia, Campus of Cuiabá, Universidade Federal de Mato Grosso (UFMT).

We thank M. Hayes for valuable suggestions on the manuscript and we are grateful to Biodinâmica Engenharia e Meio Ambiente for logistical support.

AMEIVA AMEIVA (Giant Ameiva). **SAUROPHAGY.** *Ameiva ameiva* is one of the most widely distributed Neotropical lizards, occurring from the Caribbean Islands and Costa Rica to southern Brazil, northern Argentina, and the eastern Andes in South America (Vanzolini et al. 1980. Répteis das Caatingas. Acad. Bras. de Ciênc., Rio de Janeiro, Brazil. 161 pp.; Vitt and Colli 1994. Can. J. Zool. 72:1986–2008). The diet of *A. ameiva* is composed mainly of arthropods (Vitt and Colli 1994, *op. cit.*). Gastropods and plant matter (fruits and leaves) are also commonly present (Vitt 1995. Occ. Pap. Oklahoma Mus. Nat. Hist. 1:1–29; Zaluar and Rocha 2000. Ciência e Cultura 52:101–107). Orthopterans, termites, beetles, and insect larvae are the most numerically important items in the diet of the populations of this species within different Brazilian ecosystems (Gainsbury and Colli 2003. Biotropica 35:503–519; Vitt and Colli 1994, *op. cit.*). Volumetrically, cockroaches, beetles, insect larvae, spiders, and orthopterans were among the most important items in a great number of studies (Vitt and Colli 1994, *op. cit.*; Zaluar and Rocha 2000, *op. cit.*). In addition to invertebrates and plant matter, *A. ameiva* occasionally feeds on small vertebrates (Vitt 1995, *op. cit.*), including lizards (Vitt 2000. Herpetol. Monogr. 14:388–400; Zaluar and Rocha 2000, *op. cit.*). Here, we report on the ingestion of a lizard previously unrecorded as prey for *A. ameiva* in the caatinga at the Ecological Station of the Seridó (ESEC Seridó), in the municipality of Serra Negra do Norte, Rio Grande do Norte, Brazil.

During the ecological study of a population of *A. ameiva* in the ESEC Seridó (06.5767°S, 37.2558°W, datum: WGS84; elev. 192 m), a total of 18 stomachs were analyzed. A gymnophthalmid lizard, *Vanzosaura rubricauda* (24.0 mm SVL, 35.0 mm in total length, 6.0 mm in width and 659.4 mm^3 in volume) was found in

the stomach contents of an adult female (125.7 mm SVL) captured on 29 March 2009, near decomposing trunks in herbaceous vegetation.

In an analysis of 55 stomachs of *A. ameiva* conducted by Zaluar and Rocha 2000 (*op. cit.*) in a restinga ecosystem in southeastern Brazil, juveniles of two sympatric lizard species (*Tropidurus torquatus* and *Mabuya agilis*) were found in the stomachs of two adult males. Vitt 2000 (*op. cit.*) reports on the predation of two *Kentropyx striata* adults by an adult *A. ameiva* in an Amazonian savanna in northern Brazil. Owing to the large body size of *A. ameiva* compared to many sympatric lizard species throughout its wide distribution, saurophagy may be more common than is currently represented in the literature (Vitt 2000, *op. cit.*).

The *A. ameiva* (CHBEZ 2507) was deposited in the herpetological collection of the Universidade Federal do Rio Grande do Norte, Natal, Brazil. We thank the Conselho Nacional de Desenvolvimento Científico e Tecnológico (CNPq) for financing the PELD-Caatinga Program entitled Structure and Functioning, and for the research scholarship granted to RFDS (process 127543/2008-2), LBR (process 141993/2006-5) and EMXF (process 304077/2008-9); and to PROPESQ/UFRN for the research scholarship awarded to HWBA. IBAMA provided a permit (Permit 206/2006 and Process 02001.004294/03-15).

FREIRE** (e-mail: elizajuju@ufrnet.br)[1,2], [1]Laboratório de Herpetologia, Departamento de Botânica, Ecologia e Zoologia, Centro de Biociências, Universidade Federal do Rio Grande do Norte, Campus Universitário, 59072-970, Natal, RN, Brazil; [2]Programa de Pós-graduação em Psicobiologia/UFRN, 59078-970, Natal, RN, Brazil.

AMPHISBAENA VERMICULARIS (NCN). **PREDATION.** Amphisbaenians are little known and secretive animals, but it is recognized that elapid snakes of the genus *Micrurus* are important predators. *Amphisbaena vermicularis* is a small amphisbaenian (325 mm total length) known from the Brazilian states of Pará to Minas Gerais, Mato Grosso, and Mato Grosso do Sul, usually in Caatinga domains (Uetanabaro et al. 2007. Biota Neotropica 7:279–289; Vanzolini et al. 1980. Répteis das Caatingas. Acad. Bras. de Ciênc., Rio de Janeiro, 161 pp.). Here, we document the predation of *A. vermicularis* by the elapid *Micrurus ibiboboca*, a widespread reptile within the Caatinga region of eastern Brazil (Roze 1996. Coral Snakes of the Americas: Biology, Identification, and Venoms. Krieger Publ. Co., Malabar, Florida. 328 pp.; Vanzolini, *op. cit.*) and a known amphisbaenian predator (Gomes et al. 2005. Herpetol. Rev. 36:170).

At 2100 h on 23 August 2007, one of us (CMCAL) collected an adult female *M. ibiboboca* that was in a residence in the municipality of Natal (3.1221ºS, 43.2122ºW; datum: SAD69; elev. 41 m). The residence's owner killed the snake, exposing its stomach which contained the recently ingested amphisbaenian prey. The prey was 203 mm SVL, 25 mm tail length, 4.54 g and the snake was 577 mm SVL, 34 mm tail length and 46.2 g.

The snake and amphisbaenian prey were deposited in the herpetological collection of Universidade Federal do Rio Grande do Norte, Natal municipality, under numbers CHBEZ 1910 and CHBEZ 1911, respectively.

Submitted by **CAROLINA M. C. A. LISBOA (**e-mail: carolisboabio@yahoo.com.br), and **ELIZA M. X. FREIRE** (e-mail: elizajuju@ufrnet.br), Departamento de Botânica, Ecologia e Zoologia, Centro de Biociências, Universidade Federal do Rio Grande do Norte, 59072-970, Natal, RN, Brazil.

BARISIA IMBRICATA (Transvolcanic Alligator Lizard). **RECORD LITTER SIZE.** The viviparous anguid lizard *Barisia imbricata* occurs in the Mexican Transvolcanic axis (Flores-Villela 1993. Spec. Publ. No. 17, Carnegie Museum of Natural History, 73 pp). The species is widespread in several states that are a part of this axis, including Morelos, Mexico, Michoacán, Puebla, Oaxaca, Veracruz, Hidalgo, and Distrito Federal (Smith and Taylor 1966. Herpetology of Mexico. Annotated Checklist and Keys to the Amphibians and Reptiles. Eric Lundberg, Asthon, Maryland). Lizards of the genus *Barisia* have been poorly studied in aspects of their reproduction; however, there are data available for litter sizes among various subspecies of *B. imbricata*. For example, it has been reported that *B. imbricata imbricata* has a mean litter size of 6.9 (Guillette and Casas-Andreu 1987. Herpetologica 43:29–38), and there is a single report for a litter of 10 neonates (Navarro-López et al. 2003. Bol. Soc. Herpetol. Mex. 11:51–52). Other subspecies are recorded to have similar mean litter sizes: 6.9, *B. i. ciliaris*; 7.2, *B. i. jonesi*; 7.7, *B. i. planifrons* (Guillette and Casas-Andreu, *op. cit.*).

On 12 May 2009, during a field trip to El Pedregal, Municipality of Coyoacac, Mexico State, Mexico (19.24594°N, 99.45181°E; datum WGS84; elev. 2614 m), two gravid females were found in oak-pine forest with snout–vent lengths (SVL) of 132.4 mm and 123.0 mm, and body mass of 42.0 and 40.0 g, respectively. They were collected and housed in the laboratory in a terrarium. Two weeks later (May 26), the first female gave birth to 20 offspring (mean SVL = 32.8 mm [29.5–35.2 mm]; mean weight = 0.546 g [0.41–0.68 g]; mean tail length (TL) = 45.5 mm [38.0–50.7 mm] Fig. 1). The second female also gave birth to 20 offspring (May 31) (mean SVL = 33.4 mm [30.6–35.7 mm]; mean weight = 0.759

FIG. 1. Fifteen of 20 offspring from a single litter of *Barisia imbricata* from El Pedregal Municipality of Mexico State, Mexico.

g [0.65–0.87 g], mean TL = 45.7 mm [38.7–49.2 mm]). Offspring of the first female had a lower collective body mass than that of the combined offspring of the second female ($t = 11.7$, $P < 0001$), but the two litters were similar in SVL and TL ($P = 0.313$). These records for *B. imbricata* litter size suggest that variation exists in the reproductive characteristics among populations of this species.

We thank A. Leyte Manrique for logistical assistance, and Jackson Shedd for improving the manuscript. We also thank the projects CONACYT-S 52552-Q and FOMIX-CONACYT-43761.

Submitted by **CHRISTIAN BERRIOZABAL-ISLAS** (e-mail: bitiscaudalis@hotmail.com)**, AURELIO RAMÍREZ-BAUTISTA** (e-mail: aurelior@uaeh.edu.mx), and **URIEL HERNÁNDEZ-SALINAS** (e-mail: uhernndez3@gmail.com), Centro de Investigaciones Biológicas (CIB), Universidad Autónoma del Estado de Hidalgo, A.P. 1-69 Plaza Juárez, C.P. 42001, Pachuca, Hidalgo, México.

BARISIA LEVICOLLIS (Chihuahuan Alligator Lizard). **REPRODUCTION.** *Barisia levicollis* is currently known only from the state of Chihuahua, Mexico where it is limited to the Sierra Madre Occidental at elevations of about 2500 m (Lemos Espinal and Smith 2007. Amphibians and Reptiles of the State of Chihuahua, Mexico. Universidad Nacional Autónoma de México, Comisión Para el Conocimiento y uso de la Biodiversidad, México, D.F. 613 pp.). The purpose of this note is to provide the first information on its reproduction.

One *B. levicollis* female (142 mm SVL) was examined from the herpetology collection of the Natural History Museum of Los Angeles County (LACM), Los Angeles, California (LACM 75502). It was collected 14 September 1971 in Chihuahua, 17 km NE El Largo (29.6833°N, 108.4500°W, WGS84; elev. 2150 m).

A small slit was made in the lower part of the abdomen to expose the ovaries. A total of 13 vitellogenic eggs (5 mm diameter) were counted (*in situ*). This September evidence of ovarian activity indicates *B. levicollis* exhibits an autumn reproductive period similar to some New World anguids: *Barisia imbricata* (Guillette and Casas-Andreu 1987. Herpetologica 43:29–38), *Elgaria kingii* (as *Gerrhonotus kingi*) (Goldberg 1975. Southwest. Nat. 20:412–413), and *E. paucicarinata* (Goldberg and Beaman 2004. S. California Acad. Sci. 103:144–146).

I thank C. Thacker (LACM) for permission to examine *B. levicollis.*

CALOTES ROUXI (Forest Dwarf Calotes). **CAPTIVE REPRODUCTION AND BREEDING BEHAVIOR.** On 5 May 2008, during one of our field studies in the forest belt of the village of Kanakumbe (15.6933333°N, 74.2166667°E; WGS84), Western Ghats in Karnataka State, India (2500 m elev.), *Calotes rouxi* were observed on tree trunks. Nuptial coloration was evident in males in that the head and nuchal area were brick red. Some females appeared gravid based on the bulge of their abdomens. We collected one male (SVL 7.34 cm; body mass 10 g) and one gravid female (SVL 6.26 cm; body mass 8 g) and brought them to our laboratory and maintained them in an outdoor terrarium. All sides of the terrarium were made up of aluminum mesh except for the bottom, which had sand substratum of ~ 8 cm. The terrarium housed dry twigs that served as perches for the lizards and small herbs and grasses grew on the substratum. It also housed broken earthen pots and bricks that provided refugia for the lizards. The lizards were fed insects including grasshoppers and moths every other day. On 29 July 2008, 30 days after they were housed in the terrarium, the female appeared to have laid the eggs based on her flattened abdomen. Upon searching the substratum, we found five eggs. The eggs were about 3 cm deep in the nest. Apparently, the female had dug the nest in the soil, oviposited eggs, and then covered them with soil as we have observed in other agamid species including *Calotes versicolor*, *Psammophilus dorsalis*, and *Sitana ponticeriana*. These eggs were retrieved from the nest and incubated on moist sand substratum in a plastic box at ambient temperature following the procedure adopted for *C. versicolor* (Radder et al. 2002 Amphibia-Reptilia: 23:71–82). All eggs hatched on day 45 following oviposition. Mean snout–vent length (SVL) of these hatchlings was 23.3 ± 0.32 mm and mean body mass was 400 mg.

Interestingly, the day after oviposition, the adult male in the terrarium developed brick red nuptial coloration in the anterior part of the body including the head, began exhibiting courtship behavior composed of characteristic four-legged push-up and gular displays, and attempted to mate with the female, but was unsuccessful. The coloration disappeared soon after the male ceased courtship behavior. However, the next day, on 30 July 2008, the red nuptial coloration reappeared and a successful mating was observed between the pair. The male then lost his nuptial coloration again soon after the mating**.** Within a week of that mating, abdominal palpation revealed gravidity of the female. The female retained eggs for ~ 60 days and laid a second clutch of seven eggs on 2 September 2008 following heavy rainfall. All eggs hatched successfully after 44 days of incubation. The hatchling SVL measured 23.4 ± 0.13 mm and weight was 314.29 ± 14.29 mg.

This study is the first report on breeding behavior and reproduction in this species The fact that the same female laid more eggs in the second clutch suggests that the food (insects) provided was adequate and met the energy requirements for reproduction under captive conditions. We have been successful in rearing and breeding captive born *Calotes versicolor* in the outdoor terraria for the last 6–7 years. The present study demonstrates that outdoor terraria meant for captive breeding of *C. versicolor* was equally congenial for breeding of wild caught *C. rouxi* as well.

This work was supported by UGC-SAP II (DRS) Program of University Grants Commission, New Delhi.

CNEMIDOPHORUS OCELLIFER (Spix's Whiptail). **USE OF SCORPIONS AS PREY IN AN UNSTABLE ENVIRONMENT.** Whiptail lizards **(***Cnemidophorus*) are terrestrial, active-foraging teiids that consume primarily sedentary prey, such as termites and insect larvae (Vitt 1991. J. Herpetol. 25:79–90). *Cnemidophorus*

ocellifer exploits termites, orthopterans and spiders in the dry forests (Caatinga) of Northeastern Brazil (Vitt 1995. Occas. Pap. Oklahoma Mus. Nat. His. 1:1-29). We recorded a high frequency of predation on scorpions by this lizard on alluvial terraces of the lower São Francisco River, in Sergipe, Brazil (Caatinga Dominion).

Data were collected at the Monumento Natural Grota do Angico (9.6622222°S, 37.6697222°E; datum SAD-69), on the right bank of the São Francisco River, where alluvial terraces are formed by sand deposited during river floods, believed to occur naturally once a century (Dominguez and Brichta 1997. Estudos sedimentológicos a montante da UHE de Xingó. Sergipe: Cad. Arqueol. MAX). However, following the construction of the Xingó hydroelectric dam in 1994, 15 km upriver from the site, floodgates are opened every few years (most recently in 2003), flooding the terraces downriver and replenishing associated biota, but leaving sandy shores with sparse vegetation along the river bank.

Between October and November 2008, ten specimens of *C. ocellifer* were collected during the dry season. The examination of stomach contents revealed the presence of scorpions in seven lizards, ranging from one to three scorpions per stomach, as well as fragments. Coleoptans and orthopterans were recorded in four specimens, and spiders and ants in three. No termites were recorded. According to A.P.L. Giupponi (Museu Nacional, Rio de Janeiro, pers. comm.), at least two species of scorpions occur in the area, *Bothriurus rochai* and *Rhopalurus rochai*. It is relevant to note that *Cnemidophorus* are diurnal lizards, while scorpions are strictly nocturnal. This suggests that *C. ocellifer* may be targeting scorpion shelters during active foraging, possibly due to a scarcity of other resources in a poor and unstable environment, caused by frequent flooding and accentuated by the severe dry season at Caatinga, exhibiting considerable ecological flexibility.

We are grateful to Alessandro Ponce de Leão Giupponi for information on the scorpions of the Monumento Natural Grota do Angico and to Steve Ferrari for the careful revision of the manuscript.

COPHOSAURUS TEXANUS (Greater Earless Lizard). **MORTALITY.** *Cophosaurus texanus* is distributed from southern portions of Arizona, New Mexico, and Texas and south from northeastern Sonora and Chihuahua to northern San Luis Potosí and western Tamaulipas, Mexico (Conant and Collins 1998. Reptiles and Amphibians of Eastern/Central North America. 3rd ed., Houghton Mifflin Co., Boston, Massachussets 450 pp.; Lemos Espinal and Smith 2007. Anfibios y Reptiles del Estado de Coahuila, México. CONABIO. México. 550 pp.). *Cophosaurus texanus* is known to prey on at least 12 different arthropod taxa (Maury 1995. J. Herpetol. 29:266–272; Kasson 2001. Herpetol. Rev. 32:40). Saurophagy has been reported (Castañeda et al. 2005. Herpetol. Rev. 36:174).

FIG. 1. Partial carcass of an adult *Cophosaurus texanus* found in Nuevo Leon, Mexico. Cause of death appears attributable to ingestion of a red rubber balloon, remains of which are clearly visible within the decomposing body.

On 8 February 2009, during an arachnid faunal survey at La Huasteca in the municipality of Santa Catarina in Nuevo Leon, Mexico, we encountered the trunk and limbs of a dead *C. texanus* (57 mm length, 17 mm width, 2.48 g) at 1330 h with a piece of red rubber balloon (49 mm length and 16 mm width) inside the decomposing body (Fig. 1), this material apparently being the cause of death. This locality is frequently visited by a large number of local tourists whose poor ecological and conservation practices result in a great amount of litter. The rubber balloon was apparently ingested by the lizard, but why and how remain a mystery.

A probable case of envenomation resulting in death of *C. texanus* caused by the ingestion of honeybees (*Apis mellifera*) has been documented (Mata-Silva et al. 2006. Herpetol. Rev. 37:464). Here we document for the first time the death of an adult *C. texanus* by an anthropogenic product and note the impact of litter on herpetofauna.

The lizard was collected, identified, measured, weighed, photographed, and deposited in the herpetological collection of the Facultad de Ciencias Biologicas/UANL (UANL 6997). We thank Pamela Gonzalez del Pliego Castañeda for use of the photograph.

Submitted by **JERÓNIMO A. CHÁVEZ CISNEROS**, **DAVID LAZCANO** (e-mail: dlazcanov@hotmail.com), and **M. ALEJANDRA SALINAS CAMARENA**, Universidad Autónoma de Nuevo León, Facultad de Ciencias Biológicas, Laboratorio de Herpetología, Apartado Postal - 513, San Nicolás de los Garza, Nuevo León, C.P. 66450, México.

CORYTOPHANES CRISTATUS (Smooth Helmeted Iguana). **ENDOPARASITES.** *Corytophanes cristatus* is known from lowland and premontane areas of central Veracruz and the Yucatán Peninsula, Mexico south to northwestern Colombia; it is strictly arboreal (Savage 2002. The Amphibians and Reptiles of Costa Rica. A Herpetofauna Between Two Continents, Between Two Seas. University of Chicago Press, Chicago, Illinois. 934 pp.).

To our knowledge, there is one report of helminths; Bursey et al. (2007. Comp. Parasitol. 74:108–140) reported *Cyrtosomum longicaudatum* and *Macdonaldius grassi* in specimens of *C. cristatus* collected in Panama. The purpose of this note is to add to the helminth list of *C. cristatus.*

Four *C. cristatus* (SVL = 97.5 mm ± 8.3 SD, range = 89–106 mm) were borrowed from the herpetology collection of the Natural History Museum of Los Angeles County (LACM), Los Angeles, California and examined for helminths (LACM 131039–131042 collected August 1979, in Costa Rica, Limón Province ca. 46 km W Tortuguero, 10.4166°N, 83.6000°W, WGS84; elev. 25 m). The body cavity was opened by a longitudinal incision and the digestive tract was removed, and the stomach and intestines were opened and examined using a dissecting microscope. Only nematodes were present. These were placed on microscope slides, cleared in glycerol, coverslipped, and studied under a compound microscope.

Found in LACM 131040 (large intestine) were 220 *Cyrtosomum longicaudatum* (prevalence = number infected lizards/number lizards examined = 25%) and 199 *Cyrtosomum mega* (prevalence = 25%); LACM 131042 (large intestine) contained 128 *Africana telfordi* (prevalence = 25%). Voucher endoparasites were deposited in the United States National Parasite Collection (USNPC), Beltsville, Maryland as *Cyrtosomum longicaudatum* (USNPC 102114), *Cyrtosomum mega* (USNPC 102115) and *Africana telfordi* (USNPC 102116).

Cyrtosomum longicaudatum was described from *Ctenosaura similis* collected in Costa Rica by Brenes and Bravo Hollis (1960. Libro Homenaje al Dr. Eduardo Caballero y Caballero. Universidad Autónoma de México, México City, pp. 451–464) and is frequently reported from Central American lizards; a host list will be found in Bursey et al. (*op. cit.*). *Cyrtosomum mega* was described from *Cyclura carinata* from the Caicos Islands, West Indies by Bowie and Franz (1974. J. Parasitol. 60:628–631). *Corytophanes cristatus* is the second host reported to harbor this nematode. *Africana telfordi* was described from *Enyalioides heterolepsis* from Panama by Bursey and Goldberg (2002. J. Parasitol. 88:926–928). It was also reported in *Gonatodes albogularis* from Panama by Bursey et al. (*op. cit.*). *Corytophanes cristatus* is the third known host to harbor this nematode.

Species of *Africana* and *Cyrtosomum* are nematodes that do not utilize an intermediate host (Anderson 2000. Nematode Parasites of Vertebrates. Their Development and Transmission, 2nd ed. CABI Publishing, Wallingford, UK. 650 pp.). Infection likely occurs by ingestion of eggs from contaminated substrate. Pearce and Tanner (1973. Great Basin Nat. 33:1–18) considered species of *Cyrtosomum* to be commensals that feed on fecal matter in the large intestine rather than parasites. *Corytophanes cristatus* represents a new host record for *Africana telfordi* and *Cyrtosomum mega*. Costa Rica is a new locality record for both species.

We thank C. Thacker (LACM) for permission to examine specimens and C. Nava (Whittier College) for assistance with dissections.

Submitted by **STEPHEN R. GOLDBERG,** Department of Biology, Whittier College, Whittier, California 90608, USA (e-mail: sgoldberg@whittier.edu); and **CHARLES R. BURSEY,** Department of Biology, Pennsylvania State University, Shenango Campus, Sharon, Pennsylvania 16146, USA (e-mail: cxb@psu.edu).

CTENOTUS REGIUS (Regal Striped Skink). **PREDATION.** The largest group of lizards in Australia belong to the genus *Ctenotus*, which contains close to 100 species. The species in this genus occur throughout much of Australia, particularly in arid and semi-arid regions (Cogger 2000. Reptiles and Amphibians of Australia, 6th ed. Reed New Holland, Sydney, 808 pp.). The ecology of many of these species remains poorly known, including predators and description of predation events. Here we present an observation of an immature Grey Butcherbird (*Cracticus torquatus*) preying on *Ctenotus regius*.

At 1230 h on 13 April 2009, south of Lake Becking, Murray-Sunset National Park (Victoria, Australia) (35.0380°S, 141.7138°E), in degraded *Allocasuarina*/*Callitris* woodland on red sands, bordering mallee country, a Grey Butcherbird flew from a mallee *Eucalyptus* ~25 m to the ground beneath another mallee. The butcherbird stayed on the ground for ~10 seconds where it became obvious that it had captured a skink, later identified as *Ctenotus regius.* The butcherbird then flew to the lower branch of a dead *Callitris* with the *C. regius* in its bill. It proceeded to hop up the branches and wedged the skink in the fork of the frayed hollow spout of the tree and began tearing at the skink. This method is commonly used by butcherbirds for handling larger prey items and for caching (Higgins et al. [ed] 2006. Handbook of Australian, New Zealand and Antarctic Birds Vol. 7 Boatbill to Starlings. Oxford Univ. Press, Melbourne. 1992 pp.). Upon our approach to photograph and identify the skink, the butcherbird hurriedly tore off the rear half of the skink and flew off (Fig. 1).

Grey Butcherbirds prey on invertebrates, mainly insects, and small vertebrates, especially small birds and their nestlings (Higgins et al. 2006, *op. cit.*). Grey Butcherbirds are known to take skinks (e.g., Barker and Vestjens 1991. The Food of Australian Birds 2. Passerines. CSIRO, Canberra, 557 pp.; Davis and Recher 1998. West. Aust. Nat. 22:135–136; Lea and Gray 1935. Emu 35:335–347; Rose 1999. Aust. Bird Watcher 18:164–178) but the identity of the skink species are rarely recorded. No *Ctenotus* species have been recorded in the diet of Grey Butcherbirds nor other *Cracticus* species, including the widespread and well-studied Australian Magpie (*C. tibicen*) (Higgins et al. *op cit.*).

Ctenotus regius occurs in Australia's semi-arid interior in woodlands and shrublands on heavy to sandy reddish soils in association with spinifex (Swan and Watharow 2005. Snakes, Lizards and Frogs of the Victorian Mallee. CSIRO Publishing, Collingwood. 104 pp.; Wilson and Swan 2008. A Complete Guide to Reptiles in Australia 2nd ed., New Holland, Sydney. 512 pp.) and overlaps with the range of Grey Butcherbirds throughout much of its distribution. *Ctenotus regius* and other *Ctenotus* species occurring in this range (e.g., Coventry 1996. Proc. Roy. Soc. Victoria 108:107–119) are likely to be prey for this and other *Cracticus* species.

Aumann (2001. Wildl. Res. 28:379–393 and supplementary appendices) found that a number of diurnal raptor species took a small number of *Ctenotus* species in arid central Australia. However, Pianka (1969. Ecology 50:1012–1030) believed it "doubtful" that many *Ctenotus* in the Great Victoria Desert species fall prey to birds or mammals due to the unlikelihood that these predators would pursue the skinks into dense *Triodia* tussocks. Pianka (1969, *op. cit.*) found the main predators of *Ctenotus* in that region to be *Varanus* monitors and elapid snakes. Read (1998. Aust. J. Zool. 46:617–629) suggested that larger *Ctenotus* such as *C. regius*

FIG. 1. A Regal Striped Skink (*Ctenotus regius*) wedged in the fork of a tree and dismembered by a Grey Butcherbird (*Cracticus torquatus*) in Murray-Sunset National Park, Australia.

conserve energy by remaining inactive on many days, regardless of food availability or temperature and thereby may decrease their risk of predation. Henle (1989. Acta Oecologica Oecologia Generalis 10:19–35) considered that it is likely that predation generally plays an important role in segregating lizard communities, including those containing *C. regius*, but does not describe the types of predators.

The apparent preference for more open woodlands by *C. regius* in northwest Victoria (Coventry 1996. Victorian Nat. 113:289–299) and their habit of actively foraging around ground vegetation (Swan and Watharow 2005, *op. cit.*) may make this species more susceptible to predation by birds than others in the genus.

Thanks to Andrew Bennett and Dale Nimmo for identification of the skink.

CYCLURA CYCHLURA INORNATA (Allen Cays Rock Iguana). **PARAPHIMOSIS AND PROLAPSED CLOACA**. In reptiles, several problems can arise involving the cloaca and the prolapse of different organs (e.g., colon, oviducts, hemipenes, etc.; see Bennett and Mader 2006. *In* Mader [ed.], Reptile Medicine and Surgery, pp. 751–755. Elsevier/Saunders, St. Louis, Missouri; Barten 2006. *In* Mader [ed.], *op. cit.*, pp. 862–864; DeNardo 2006. *In* Mader [ed.], *op. cit.*, pp. 376–390). Published observations of cloacal prolapse in natural populations of reptiles are relatively rare (see Pernetta and Reading 2009. Herpetol. Rev. 40:95). Here we report two observations of prolapse from the cloaca in the Allen Cays Rock Iguana (*Cyclura cychlura inornata*) from Leaf Cay and Southwest Allen Cay in the Bahamas (24.75°N, 76.83°W; see Iverson et al., 2004: Herpetol. Monogr. 18:1–36 for a detailed description of the study area).

On 9 May 2001, we observed an adult male (snout–vent length, SVL = 35.0 cm, SVL) on Leaf Cay with a prolapsed right hemipenis that was hard and shriveled. This male was subsequently captured in 2002, 2003, and 2004 with no obvious health problems, and no evidence of the prolapsed hemipenis. He was not subsequently captured between 2005 and 2009, but may have been poached or died of other causes. Prolapsed hemipenes typically arise from damage to the hemipenis during copulation (Barten 2006, *op. cit.*; DeNardo 2006, *op. cit.*).

On 29 March 2008 we observed a large female (SVL = 32.0 cm, SVL) with a prolapsed cloaca on Southwest Allen Cay (Fig. 1). This female was found to have an elevated corticosteroid level (30.6 ng mL-1) compared to others in the population (mean = 5.9 ng mL-1) as determined by blood tests conducted on samples collected within three minutes of capture to avoid increased glucocorticoid concentrations (see Romero and Wikelski 2002. Biol. Conserv. 108:371–374). She was subsequently found dead less than two months later on 14 May 2008. Cloacal prolapse can occur due to straining during oviposition or straining during defecation due to constipation or other causes (Bennett and Mader 2006, *op. cit.*). Of particular concern for the Allen Cays Rock Iguana is the potential increase in strained defecation due to the feeding of iguanas by tourists. Diets high in grapes, the most commonly provided food item, result in sand and liquid-filled scat that dries to a cement-like consistency (Fig. 2; see also Hines 2007. Iguana 14:243). The density of these cement-like scats is greater than those formed from a natural diet of leaves and fruits, potentially increasing the incidence of constipation and tenesmus, and thereby cloacal prolapse. The death of this female suggests that cloacal prolapse may result in

FIG. 1. Prolapsed cloaca of a female Allen Cays Rock Iguana found on Southwest Allen Cay, Exumas, Bahamas in March 2008.

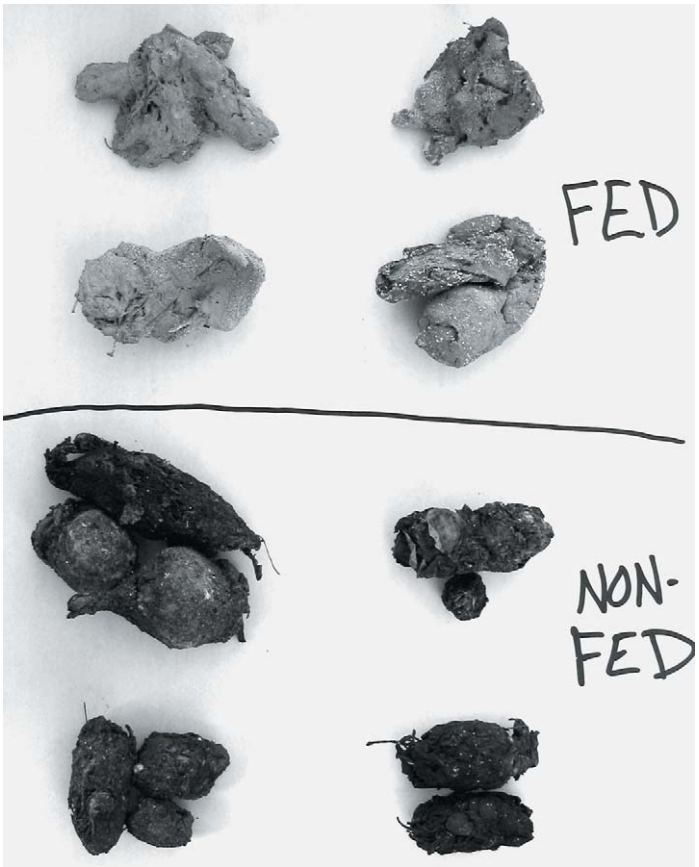

FIG. 2. Comparison of scat samples from the tourist feeding beach (top) versus non-visited areas (bottom) of Leaf Cay, Exumas, Bahamas.

death, or alternatively, may be a sign of another health issue that may result in death.

DELMA IMPAR (Striped Legless Lizard) **REPEATED USE OF COMMUNAL NESTING SITE**. Communal nesting is a reproductive trait commonly observed in some groups of reptiles (Graves and Duvall 1995. Herpetol. Monogr. 9:102–119). The benefits of communal nesting may include a response to the limited availability of suitable nest sites in the environment due to thermal, hydric and anti-predator constraints, or fitness benefits for offspring born in a cluster of eggs (Radder and Shine 2007. J. Anim. Ecol. 76:881–887). The trait has been identified in some species of pygopodids, a family of flap-footed snake and worm-like lizards confined to the Australian region (Greer 1989. The Biology and Evolution of Australian Lizards. Surrey Beatty & Sons Pty Limited, Chipping Norton, N.S.W. 264 pp.). This family includes the Striped Legless Lizard, *Delma impar*, with females known to lay a single clutch of up to two eggs annually in early summer. Communal nesting has so far been reported three times in this species; once with four eggs and twice with six eggs clumped together in substrate cavities or under rocks, inferring the joint use of a nesting site by at least two and three female *D. impar*, respectively (Banks et al. 1999. Herpetofauna 29:18–30; Coulson 1995. Management Directions for the Striped Legless Lizard (*Delma impar*) in the Australian National Territory. ACT Parks & Conservation Service, Canberra, ACT; Mills 1992. Report of *Delma impar* trapping survey conducted at Werribee, Jan–Feb 1992. Unpubl. report to the Striped Legless Lizard Working Group, Victoria). Further information on this aspect of the species' reproductive biology is important for its management and conservation, as *D. impar* is listed as threatened under state, national, and international legislations (Smith and Robertson 1999. National Recovery Plan for the Striped Legless Lizard (*Delma impar*): 1999–2003. Environment Australia, Canberra) and general knowledge of its biology is sparse.

As part of an intensive survey program for this species in Western Victoria, southeastern Australia, we report the repeated use of an artificial, communal nesting site exceeding the aggregations reported previously and discuss environmental parameters associated with the site. In 2000, four survey grids were established in native grassland on a private property near Hamilton in Western Victoria with the aim of determining the presence of *D. impar*. Each survey grid consisted of fifty roof tiles arranged in a 20 × 45m grid formation. Grids were monitored first annually, and since 2005, quarterly, with the presence of all terrestrial vertebrate fauna within the grids recorded. On 9 December 2007 we captured two female *D. impar* (90 and 93 mm SVL) that appeared to be gravid and also noted the presence of six *D. impar* eggs deposited in a prominent soil crack underneath a single tile on grid #1 (37.5016°S, 142.3314°E). We released the gravid females within an hour underneath the same tile and returned on 20 April 2008 and retrieved, with minimum disturbance to the crack, a total of 32 eggs shells. This finding infers a communal nesting site with contribution of at least 16 female *D. impar*. On 30 November 2008 we attached a temperature data logger (Thermochron iButton®, Dallas Semiconductor) programmed to collect temperature (± 0.5°C) every hour until 31 January 2009 beneath the above roof tile with the data logger situated just above the soil crack. On 5 January we returned and briefly lifted the tile and confirmed the presence of at least six *D. impar* eggs. On 27 March 2009 we collected a total of 16 egg shells from the soil crack, again with minimal disturbance. This inferred that the same nesting site had been used again by at least eight females. Data logger records showed that temperatures underneath the roof tile between 1 December 2008 and 31 January 2009 had ranged from 3°C to 72°C (mean = 23.6°C, SD = 15.52).

The site on which the four grids were established is one of a few remaining large, high-value natural temperate grassland remnants on the Victorian Volcanic Plain. The site consists of mostly intact native grassland vegetation and soil crust with submerged volcanic rocks along the slopes of a creek gully. The conservation status of *D. impar* is increasingly being linked to the survival of such remnant habitats so that the presence of a large number of gravid *D.*

impar at this site may not be surprising and treated as an indication of the ecological value of the habitat. In the greater context of the project, this is the only communal nesting site discovered so far underneath roof tiles across 73 survey grids where *D. impar* has been detected (3650 roof tiles lifted approximately 43,800 times). The low success rate in finding such sites and the repeated use of a single communal nesting site by a large number of gravid females suggest that the species is very selective in choosing oviposition sites. It may be possible that aggregating eggs may protect them from desiccation in extreme weather conditions, like the temperature extremes displayed by our thermal data, or provide a selective fitness advantage to the offspring. More than 90% of egg shells recovered indicated successful hatching so the former may be plausible. Alternatively, suitable soil cracks or cavities with protection from predators and environmental extremes may be a limited resource (and the roof tile may have added a favorable element to produce a suitable oviposition site). Grid #1 was located on a small flood plain at the bottom of the gully with a deep layer of clay soil that cracked in summer, as opposed to shallow sandy clay horizon on the slopes. Further work to identify the oviposition preferences of the species will aid in the preparation of informed management and conservation strategies for *D. impar* in the wild.

This research was funded by the Australian Commonwealth Government via the Corangamite, Glenelg Hopkins and Wimmera Catchment Management Authorities and conducted under the Victorian Department of Sustainability and Environment (Australia) Research Permits 10002996, 10003505, and 10004675.

ROHR**, Applied Ecological Research P/L, PO Box 350, Doncaster East 3109, Victoria, Australia (e-mail: ted.rohr@aeresearch.com.au).

GERRHONOTUS PARVUS (Pygmy Alligator Lizard). **JUVENILE SIZE**. *Gerrhonotus parvus*, an anguid endemic to Nuevo León, Mexico, is known from only adult specimens (Knight and Scudday 1985. Southwest. Nat. 30:89–94; Banda-Leal et al. 2002. Southwest. Nat. 47:614–615; Banda et al. 2005. Herpetol. Rev. 36:449). Although one adult female maintained in captivity reportedly laid four eggs (Knight and Scudday, *op. cit.*), nothing has been reported on the size of the young of this species. Here, we report on the size of a juvenile *G. parvus* found in the wild.

On 1 October 2005, we found a juvenile *G. parvus* under a small rock in a canyon bottom near San Isidro, Municipio Santiago, Nuevo León. The canyon (ca. 1600 m elev.) runs east to west and is characterized by steep limestone walls covered with various agaves (*Agave* spp.), sotol (*Dasylirion* sp.), and scrub oak (*Quercus* sp.), and has intermittent pools of water, piles of leaf litter, and large rocks scattered throughout. The *G. parvus* measured 25.1 mm SVL, had an unbroken tail 28.5 mm in length, and a mass of 0.4 g. Previous reports of juvenile size in the small-bodied and closely related alligator lizard *Gerrhonotus lugoi* ranged from 37–55 mm SVL (Lazcano et al. 1993. Bull. Chicago Herpetol. Soc. 28:263–265), making the specimen of *G. parvus* reported herein one of the smallest known gerrhonotine lizards in North America.

The specimen was deposited in the Universidad Autónoma de Nuevo León Herpetological Collection (UANL 6785). Research and collecting were conducted under the authority of SEMARNAT scientific research permits OFICIO NÚM/SGPA/DGVS/01612 and 01454 issued to DL.

Submitted by **DAVID LAZCANO**, Universidad Autónoma de Nuevo León, Facultad de Ciencias Biológicas, Laboratorio de Herpetología, Apartado Postal - 513, San Nicolás de los Garza, Nuevo León, C.P. 66450, México (e-mail: dlazcanov@hotmail.com); and **ROBERT W. BRYSON, JR**., School of Life Sciences, University of Nevada, Las Vegas, 4505 Maryland Parkway, Las Vegas, Nevada 89154-4004, USA (e-mail: brysonjr@unlv.nevada.edu).

IGUANA DELICATISSIMA (Lesser Antillean Iguana). **DISPLAY BEHAVIOR**. Iguanine lizards typically use headbob displays consisting of ritualized up-and-down motions. Forms of these displays often are referred to as "signature" displays because the number and timing of motions carry information about the individual, sex, and species identity of the displaying animal. Headbob displays serve primarily in territorial maintenance, frequently are directed toward individuals at a distance, often are used in aggressive displays (most commonly by males), and occasionally by males during courtship (Martins and Lacy 2004. *In* Alberts et al. [eds.], Iguanas: Biology and Conservation, pp. 101–108. Univ. California Press, Berkeley, and references therein). Although signature displays have been described for many iguanine lizards, we present here observations of such displays in *Iguana delicatissima*.

From 5–25 June 2008, in the course of a study examining movements and allocations of time and space in a community of *I. delicatissima* at the Sunset Bay Club on Dominica, Lesser Antilles (15.4514°N, 61.4465°W; elev. ~5 m), we observed dozens of displays and videotaped six displays by males and two by females with a Sony digital video camera recorder (model DCR-TVR120).

Headbob displays were used by both males and females. Those of males were of slightly higher amplitudes than those of females and were more likely to be repeated (especially when directed toward other males). Each display consisted of two to five headbobs of decreasing amplitude, with most (six of eight videotaped displays, five by males; 16 of 18, 12 by males; and two by individuals of unknown sex, for which data were recorded) involving four sequential bobs.

The first bob was inevitably of highest amplitude (position 2 in Fig. 1), after which the head returned to the initial position (1). Headbobs 2 and 3 (positions 3 and 5, respectively) were of lower amplitude and were followed by the head dropping to below the starting point (positions 4 and 6). The final headbob was little more than a "jiggle," after which the head returned to the initial position.

Marcella & Roger Dutrieux Cools, owners of the Sunset Bay Club, work diligently to coexist with Dominica's wildlife and were very tolerant of our antics. Mr. Arlington James, Forest Officer, Forestry, Wildlife, and Parks Division, Ministry of Agriculture & the Environment, Commonwealth of Dominica, was instrumental in issuing permits to conduct research in Dominica. Protocols were approved by the Avila University Animal Care and Use Committee. Fieldwork was funded by a grant from the National Science Foundation (USA) to RP (DBI-0242589).

LEPIDOBLEPHARIS XANTHOSTIGMA (Orange-tailed Gecko). **PREDATION.** Many species of gekkonid lizards have been reported as prey of various vertebrates, such as mammals (Daugherty et al. 1994. New Zealand J. Zool. 21:317–323; Gardner 1977. *In* Baker et al. [eds.], Biology of Bats of the New World Family Phyllostomatidae, Part II. Spec. Pub., Mus. Texas Tech Univ.), birds (McKeown 1983. *In* 6th Annual Reptile Symposium on Captive Propagation and Husbandry. Zoological Consortium, Thurmont, Maryland), snakes (Bernarde et al. 2000. Rev. Brasil. Biol. 60:695–699; Downes and Shine 1997. Anim. Behav. 55:1373–1385), and lizards, including large geckos (Bauer 1990. Herpetol. Rev. 21:83–87). Invertebrate predators of geckos have also been reported, including arachnids, centipedes, mantids and ants (Bauer 1990, *op. cit.*; Henle 1990. Herpetol. Monog. 4:30–60; Henle 1993. J. Arachnol. 21:153–155; Punzo 1993. Psyche 100:151–162). Vitt et al. (2005. Herpetol. Monog. 19:137–152) reported a high rate of tail-loss in *Lepidoblepharis xanthostigma* and commented on the interest in obtaining information on their interactions with invertebrate predators; however, no predators have previously been reported for the species.

This note reports a single observation of an arthropod attack on *L. xanthostigma* on Isla Palma, Department of Valle del Cauca, approx. 1.5 km off the Pacific coast of Colombia (3.90019°N, 77.35597°W, WGS84). The island is in the tropical rain forest life zone (Holdridge 1987. Life Zone Ecology. Tropical Science Center, San Jose, Costa Rica) and has average annual precipitation of 6000 mm and 90% relative humidity—the predominant height of forest trees is between 10 and 50 m, with many shrubs and ferns in the understory (Castellanos 2003. Interacciones Tróficas y Espaciales de un Ensamblaje de Peces de Charcos Intermareales en un Acantilado Rocoso Tropical, Bahía Malaga-Pacífico Colombiano. Universidad del Valle, undergraduate thesis. Cali, Colombia, 88 pp.; Montoya 2003. Estructura de la Comunidad de Gasterópodos: Diversidad, Distribución y Abundancia con Relación a la Heterogeneidad Espacial en dos Acantilados Rocosos Intermareales de Isla Palma, Pacífico Colombiano. Universidad del Valle, undergraduate thesis. Cali, Colombia, 82 pp.). We made the observations during a light rain along the crude trail to Punta Brava near the southeastern corner of the island on 29 June 2007 at 2045 h. A spider was captured on the ground in the leaf litter with a *Lepidoblepharis xanthostigma* in the grasp of its chelicerae. Injuries on the gecko's body indicate the spider had likely attacked the gecko in at least two places. One pair of wounds involved the dorsal, occipital region of the head and dorsum of the torso behind the forelimb on the left side of the body, and a separate area with broken skin at the base of the tail, which was missing. As the spider was lifted from the ground it released the gecko, the spider was then dropped, and both ran into the leaf litter where they were recaptured. The gecko was an adult male (SVL 24.1 mm) and the spider was an unidentified species of brushed trapdoor spider (Barychelidae) of the genus *Trichopelma* (cephalothorax length 29 mm), locally known as "chicken-eating tarantula." The gecko specimen was deposited in the collections of the Museo de Ciencias Naturales "Federico Lehman" in Cali, Colombia (IMCN-Rep 197).

We are indebted to the Dirección General Marítima (DIMAR) for allowing us access to the island, to the Grupo de Ecología Animal of the Universidad del Valle for its assistance in the fieldwork, Carlos Valderrama for help with identification of the spider, and Eli Greenbaum for comments on the manuscript.

Submitted by **ANDRÉS QUINTERO-ANGEL**, Grupo de Investigación en Ecología Animal, Departamento de Biología, Universidad del Valle, Cali, Colombia (e-mail: aquinteroa@gmail.com); and **JOHN L. CARR,** Department of Biology and Museum of Natural History, University of Louisiana at Monroe, Monroe, Louisiana 71209-0520, USA (e-mail: carr@ulm.edu).

LIOLAEMUS GRACILIS (Striped Slender Lizard). **PREDATION**. *Liolaemus gracilis* occurs from northern Chubut to southern La Rioja provinces, in western Argentina (Cei 1986. Reptiles del Centro, Centro-Oeste y Sur de la Argentina, Mus. Reg. Sci. Nat. Torino, Mon. 4:1–527). Only a few data are available on its biology (e.g., Vega and Bellagamba 2005. Cuad. Herpetol. 18:3–13) and no data regarding its predators have been published. Hence, here we report an observation of *Philodryas psammophidea* predation on *L. gracilis*.

Philodryas psammophidea is a common snake in the Monte and Chaco arid and semiarid regions of western and northwestern Argentina and has been reported as a lizard-eater in general citations (Cei 1993. Reptiles del Noroeste, Nordeste y Este de la Argentina. Mus. Reg. Sci. Nat. Torino, Mon. 14:1–949). At 1030 h on 19 October 2008 during a collecting trip through western San Luis province a DOR juvenile *P. psammophidea* (sex undetermined, 490 mm SVL, 555.0 mm TL, 28 g) was found on Provincial Road 3, 43.7 km S of San Luis City, La Capital Department, San Luis province (33.6171°S, 66.4139°W, datum = WGS 84, 515 m elev.). As we were preserving the specimen, we extracted from its stomach an adult *Liolaemus gracilis* (47.0 mm SVL, 134.0 mm TL, 1.8 g). The lizard's body was nearly completely intact, with only its tail autotomized near the base and its head possessing a severe wound, probably inflicted when the snake caught it. The specimens of *L. gracilis* (LJAMM 10937) and *P. psammophidea* (LJAMM 10935) were deposited in the herpetological collection at Luciano Javier Avila Mariana Morando (LJAMM) of the Centro Nacional Patagónico – CONICET, Puerto Madryn, Argentina.

Submitted by **MONICA LILIAN KOZYKARISKI**, **NATALIA FELTRIN**, and **LUCIANO JAVIER AVILA**, CENPAT-CONICET, Boulevard Almirante Brown 2915, U9120ACF, Puerto Madryn, Chubut, Argentina (e-mail: avila@cenpat.edu.ar).

LIOLAEMUS HATCHERI (NCN). **MULTIPLE MORTALITY**. *Liolaemus hatcheri* is a small liolaemid lizard endemic to a small region in northwestern Santa Cruz Province, northern Patagonian, Argentina (Etheridge 1998. Cuad. Herpetol. 12:31–36). Only anecdotal data are known about its biology and natural history (Cei 1986. Reptiles del Centro, Centro-oeste y Sur de la Argentina. Mus. Sci. Nat. Torino Mon. 4:1–427). During field work carried out on 18 January, 2008 in Estancia Cerro Beltza (47.9937ºS, 71.6804ºW; datum: WGS84; elev. 912 m), Rio Chico Department, Santa Cruz Province, we found a population of *L. hatcheri* inhabiting a gently sloping area with highly degraded vegetation overgrazed by sheep. Lizards were found basking on medium-sized rocks scattered in the area and typically retreated to nearby rock crevices or burrows upon disturbance. Upon lifting a roughly oval-shaped, medium-sized rock (70 × 25 × 40 cm; ~30 kg) that overlaid a larger, imbedded rock, and thus provided a crevice between the two, we found three lizard carcasses that we identified by comparison with live individuals as adult specimens of *Liolaemus hatcheri* (~75 mm, SVL) (Fig. 1). This finding revealed that *L. hatcheri* use small crevices as communal shelters, but the cause of death is unclear. We hypothesize two potential causes: lizards use this refugia for temporary shelter during the normal season of activity and unusually low temperatures caused their demise inside the crevice, or the rock was moved by human or domestic livestock activity in the area and the lizards were crushed underneath. Findings on multiple deaths of *Liolaemus* in Patagonia are uncommon and formal reports are non-existent to our knowledge. Voucher specimens (LJAMM 7615–7617) are deposited in the Luciano Javier Avila Mariana Morando (LJAMM) collection housed in CENPAT-CONICET.

Submitted by **NATALIA FELTRIN**, **CRISTIAN HERNAN FULVIO PEREZ**, **MARIA FLORENCIA BREITMAN**, and **LUCIANO JAVIER AVILA**, CENPAT-CONICET, Boulevard Almirante Brown 2825, U9120ACF, Puerto Madryn (Chubut), Argentina (e-mail: avila@cenpat.edu.ar)

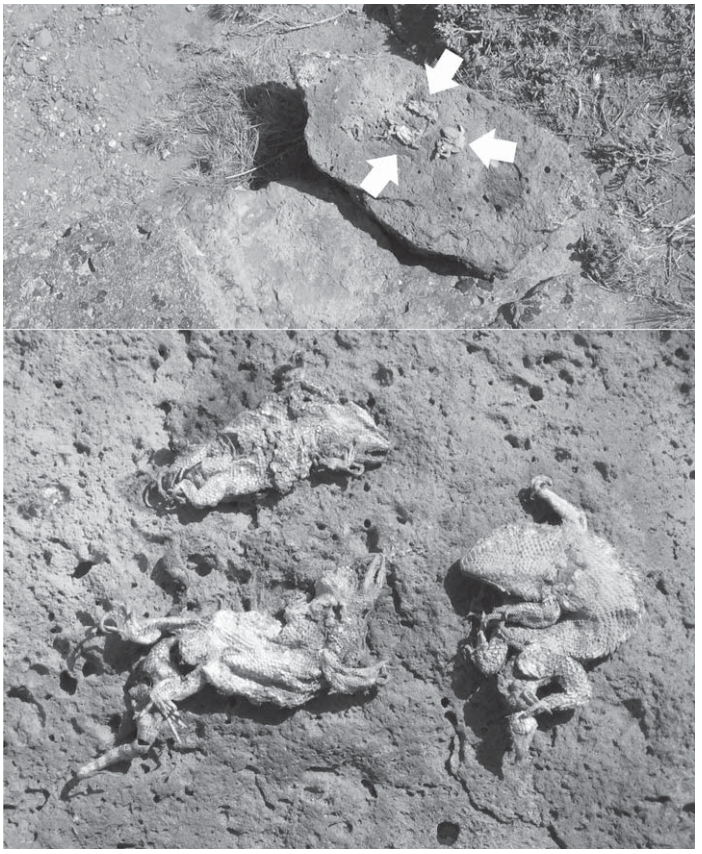

FIG. 1. Upper: general view of the site where the three lizards were found dead in the rock. Below: Detail of the three carcasses.

LIOLAEMUS OLONGASTA (NCN). **PREDATION**. *Liolaemus olongasta* is an oviparous and insectivorous, small-sized lizard inhabiting the arid landscape of Monte desert in western Argentina. Its geographic distribution ranges through central-west La Rioja to northern Mendoza provinces (Etheridge 1993. Boll. Mus. Reg. Sci. Nat. Torino 11:1–99; Sanabria et al. 2005. Herpetol. Rev. 36: 337). Only a few data are available on its biology (e.g., Canovas et al. 2006. Herpetol. Rev. 37:87–88) and no data about its predators have been published. Hence, here we report an observation of *Pseudotomodon trigonatus* predation on *L. olongasta*.

Pseudotomodon trigonatus is a rare snake, endemic to western Argentina, inhabiting mainly the Monte and southern Chaco regions and has been reported as a lizard-eater in general citations (Etheridge, *op. cit.*). At 1000 h on 19 October 2008 during a collecting trip through northern San Juan province we observed a juvenile female *L. olongasta* basking in an open area between bushes outside National Road 40, 6.5 km E Huaco River Bridge, in the road to Huaco, Jachal Department, San Juan province (30.3323ºS, 68.6537ºW, datum = WGS 84, 1096 m elev.). As we approached, the lizard ran away looking for refuge between the branches of a *Larrea cuneifolia* bush. When it reached the proximity of a small burrow between the branches, we observed the lizard's body writhing, as something appeared to be grabbing it from inside the burrow. We continued to observe this activity until only a hind limb and the tail remained outside the burrow. When we grabbed

the lizard something was still trying to pull it back into the burrow but finally we were able to pull the complete animal out with a large wound across its chest and belly. We dug into the burrow and found a *P. trigonatus* (SVL 240 mm, TL 278 mm, weigh 70 g) coiled within, which we collected after the snake attempted to flee. The specimens of *L. olongasta* (LJAMM 10699) and *P. trigonatus* (LJAMM 11087) were deposited in the herpetological collection Luciano Javier Avila Mariana Morando of the Centro Nacional Patagónico–CONICET, Puerto Madryn, Argentina.

Submitted by **MONICA LILIAN KOZYKARISKI NATALIA FELTRIN,** CENPAT-CONICET, Boulevard Almirante Brown 2915, U9120ACF, Puerto Madryn, Chubut, Argentina; **ARLEY CAMARGO,** Department of Biology, Brigham Young University, WIDB 177, Provo, Utah 84602, USA; and **LUCIANO JAVIER AVILA**, CENPAT-CONICET, Boulevard Almirante Brown 2825, U9120ACF, Puerto Madryn, Chubut, Argentina (e-mail: avila@cenpat.edu.ar).

LIOLAEMUS PETROPHILUS (NCN). **PREDATION**. Although birds are often acknowledged as feeding on lizards, direct observations of predation are relatively rare under natural conditions. *Liolaemus petrophilus* is a medium-sized lizard inhabiting the Patagonian steppe in association with rocky outcrop habitats in central Rio Negro and Chubut provinces, Argentina (Avila et al. 2006. Check List 2:66–69). Despite its abundance in its natural habitats, only recent information regarding its avian predators is available (Perez and Avila 2005. Herpetol. Rev. 36:451–452). On 13 January 2009 at ca. 1900 h, in the course of a herpetological survey carried out on the edge of a volcanic plateau, within a small valley known as Cañada La Leona (42.4084°S, 68.2615°W; datum: WGS84; elev. 1062 m), north of the town known as Gan Gan, Telsen Department, Chubut Province, CHFP observed the remains (tail with spinal axis) of a lizard *Liolaemus petrophilus* (SVL was estimated in 84 mm and a TL of 226 mm) below an American Kestrel (*Falco sparverius*) nest. The nest was on a small cliff and contained fledglings, with an adult also present. A few minutes following the initial observation, another adult kestrel arrived with an adult *L. petrophilus* in its talons. The lizard was approximately of the same size as the former dead specimen, suggesting that during summer the kestrel is an active predator of this lizard. *Falco sparverius* is widely distributed in Patagonia and is an active diurnal predator (Narosky and Yzurieta 2003. Guía para la Identificación de las Aves de Argentina y Uruguay. A.O. P., Vázquez Mazzini, Buenos Aires, Argentina. 346 pp.). It is a generalist predator known to eat lizards in summer (Figueroa Rojas and Corales Stappung 2004. Hornero 19:53–60). This is the first record of predation on *L. petrophilus* by *F. sparverius*.

Submitted by **CRISTIAN HERNAN FULVIO PEREZ**, **MONICA KOZYKARISKI**, and **LUCIANO JAVIER AVILA**, CENPAT-CONICET, Boulevard Almirante Brown 2915, U9120ACF, Puerto Madryn, Chubut, Argentina (e-mail: avila@cenpat.edu.ar).

MABUYA NIGROPUNCTATA (NCN). **PREDATION.** *Mabuya nigropunctata* occurs throughout Amazonian rain forest, living along forest edges, open patches and on the margins of terra firme forest (Avila-Pires 1995. Lizards of Brazilian Amazonia. Zool. Verh. Leiden 299; Vitt et al. 1996. J. Trop. Ecol. 13:199–220). The species is heliothermic and is often observed basking (Avila-Pires 1995, *op. cit.*). Hoogmoed (1973. Biogeographica 4:1–419) reported a *M. nigropunctata* preyed upon by a pygmy-owl (*Glaucidium* sp.), and Cunha and Nascimento (1994. Bol. Mus. Paraense E. Goeldi 9:1–191) also encountered an individual in the stomach of the snake *Siphlophis cervinus*. Herein, we report an observation of Pearl Kite (*Gampsonyix swainsonii*) predation on *M. nigropunctata*.

On 27 April 2008 at ca. 1200 h, while conducting an ornithological survey as a part of the Environmental Impact Study of the Foz do Apiacás Hydroelectric Power Plant in Mato Grosso State, Brazil, we collected an adult *G. swainsonii* with a pressure gun from a grassland area of Paranaíta, Mato Grosso (57.1092°W, 9.4155°S, datum: SAD69; elev. 701 m); dissection revealed a tail of one adult *M. nigropunctata* in the stomach. The grasslands are surrounded by rain forest dominated by Babaçu Palms (*Orbignya oleifera*).

Gampsonyix swainsonii, the smallest raptor in Brazil, inhabits open areas and forest edges (Antas 2005. Pantanal Guia de Aves: Espécies da Reserva Particular do Patrimônio Natural do SESC - Pantanal. Editora Serviço Social do Comércio, Rio de Janeiro-RJ, Brazil. 225 pp.). Previous studies of *G. swainsonii* diet report insects, birds, and unidentified lizards (Sick 2001. Ornitologia Brasileira. Editora Nova Fronteira. Rio de Janeiro, Brazil. 862 pp.).

The *G. swainsonii* specimen (JB 396 - collection license 10698-1/IBAMA) (length: 24.1 cm) and its stomach contents were deposited in Laboratório de Ornitologia, Campus of Cuiabá, Universidade Federal de Mato Grosso (UFMT).

We thank M. Hayes for valuable suggestions on the manuscript and we are grateful to Biodinâmica Engenharia e Meio Ambiente for logistical support.

MICRABLEPHARUS MAXIMILIANI (Blue-tailed Lizard). **PREDATION.** *Micrablepharus maximiliani* is a widely distributed heliothermic lizard, occurring from Brazilian Amazonia to Paraguay (Ávila - Pires 1995. Zool. Verh. Leid. 299:1–706; Peters and Donoso–Barros 1986. Bull. Uni. Stat. Nat. Mus. 297 pp.; Rodrigues 1990. Simp. Ecos. Cost. Sud. Bras. pp. 404–410; Vanzolini 1988. Proc. Work. Neotropical Distribution Patterns, pp. 317–342; Vanzolini et al. 1980. Acad. Bras. Ciên. 161 pp.). It occurs in coastal areas and the edges of forested areas where it can also be found in the isolated forest range (known locally as 'Brejos de Altitude') in the semi-arid Caatingas (Vanzolini 1974. Pap. Avul. Zool. 28[4]:61–90; Freire 1996. Rev. Bras. Zool. 13[4]:903–921; Rodrigues, *op. cit.*; Borges–Nojosa and Caramaschi 2003. Ecol. Cons. Caat. V. 01, pp. 489–540). It is commonly observed in leaf

litter, herbaceous vegetation and can be found in association with eusocial insects like termites and ants (Vitt 1991. J. Herpetol. 25:79–90; Mesquita et al. 2006. Copeia 2006(3):460–471; Sousa and Freire, *in press*, S. Amer. J. Herpetol.). Theraphosid spiders are part of the infraorder Mygalomorphae which includes a great diversity of spiders that occupy a variety of habitats and are common in Brazil, where they are known as "aranhas caranguejeiras" ('crab spiders') because of their large size (Brescovit et al. 2002. *In* Adis (org.), Amazonian Arachnida and Myriapoda, pp. 303–343). The large size of these spiders allow them to consume large invertebrates and small vertebrates (Vitt 2000. Herpetol. Monogr. 14:388–400; Brescovit et al., *op. cit.*).

Few studies are available regarding prey-predator relationship of these spiders within Brazilian communities, especially involving reptiles, due to the time required for sampling and the elusive habits of many reptiles species (Rocha and Vrcibradic 1998. Ciência e Cultura 50[5]:364–368). Here, we report on an observation of predation on *M. maximiliani* by a theraphosid spider.

At 0930 h on 1 July 2009, in the Parque Estadual Mata da Pipa (PEMP), municipality of Tibau do Sul, State of Rio Grande do Norte, Brazil (6.24861ºS, 35.05750°W, datum: WGS84; elev. 63 m), PAGS saw a medium-sized spider (~6 cm from the anterior tip of the head to the posterior end of the abdomen) in bare sand of open forest with a specimen of *M. maximiliani* grasped in its chelicerae. The lizard had no head, no front legs and no chest, but its color pattern and the absence of records of other species of this genus in the State served for a positive identification. The specimen of *M. maximiliani* could not be used for scientific collection, due to its high degree of deterioration caused by spider´s digestive enzymes.

We thank the Conselho Nacional de Desenvolvimento Científico e Tecnológico (CNPq) for the research scholarship granted to PAGS (process 127543/2008-2) and EMXF (process 304077/2008-9), Jackson D. Shedd for helpful comments on this note and Roberto Lima Santos for identifying the spider.

NOROPS CARPENTERI (NCN). **ENDOPARASITES.** Nematodes are known as endoparasites of several species of anoles (e.g., Bursey et al. 2003. J. Parasitol. 89:118–123; Dobson et al. 1992. Oecologia 91:110–117; Goldberg and Bursey 2004. Herpetol. Rev. 35:269). Herein, I report a case of nematode infestation in *Norops carpenteri*. In the Reserva Biológica Hitoy Cerere (Costa Rica, Limón Province, 9.667°N, 83.033°W, ca. 250 m elev.) on 25 August 2005, I encountered a male *N. carpenteri* on the forest floor. The anole was hardly moving and at closer examination I noticed that it was heavily infested with nematodes, apparently ascaridids. The body loop of one nematode protruded from the anole's cloaca and while I carefully handled the anole, several nematodes emerged (Fig. 1). This is the first report on endoparasites in *Norops carpenteri.*

FIG. 1. Nematodes protruding from the cloaca of *Norops carpenteri*.

Submitted by **DAVID MATTHIAS DEHLING**, Department of Ecology, Animal Ecology, Faculty of Biology, Philipps-University Marburg, Karl-von-Frisch-Straße 8, D-35032 Marburg, Germany; e-mail: Dehling@students.uni-marburg.de.

PHRYNOSOMA CORNUTUM (Texas Horned Lizard). **NESTING BEHAVIOR.** Few detailed accounts of nesting activities of the Texas Horned Lizard (*Phrynosoma cornutum*) have been published that span the early digging of a nest through oviposition and subsequent completion of an undetectable nest site. Nesting behaviors have been reported by Sherbrooke (2002. Herpetol. Rev. 33:206–208) and Allison and Cepeda (2009. Southwest. Nat. 54[2]:211–213). This note describes previously unreported behaviors during a nesting event.

At 1020 h on 25 May 2008, we observed a female (87 mm SVL; 52 g on 22 May) Texas Horned Lizard (*Phrynosoma cornutum*) excavating a nest under extremely hot, dry, windy conditions in Randall County, Texas, USA (ca. 34.98°N, 101.93°W, datum: NAD27; elev. 1080 m). Temperatures recorded for 25 and 26 May reached 32 and 33°C, respectively. At 1655 h the lizard (now 31.4 g) had laid eggs and was 10 m upslope from the site of excavation, resting in the shade of a nearby fence, but in clear view of, and intently watching, the nest site. This is the only observation we have made of a nesting female leaving the immediate area of the nest after ovipositing and before backfilling the nest, leaving the eggs exposed, and attribute it to the need for thermoregulation (lowering her body temperature). The lizard returned to, and resumed work at, the nest ca. 1855 h.

At ca. 2100 h, the lizard was working inside the nest with a large mound of loose soil outside the cavity when a violent thunderstorm approached. The storm, with 80 km/h winds (gusting to 112 km/h), hail, and driving rain, passed quickly and resulted in pea to marble sized hail, but minimal precipitation. When we checked the nest immediately after the worst of the storm had passed, the lizard and eggs were concealed within the excavation by a mound of loose soil (with the mounded soil having the appearance of a pocket gopher [Geomyidae] mound). The mound was 4–5 cm in height and 10–12 cm in diameter. However, at 0700 h the next morning, the entrance tunnel was exposed with the lizard asleep inside the

now-open tunnel, facing outward. This behavior is consistent with two other nesting events we observed in which the nest cavity and entrance tunnel remained open overnight.

Of three other nesting events we have observed, two nests were oviposited and backfilled during the night before the lizard rested (see also Sherbrooke 2002, *op. cit.*), and one nest was backfilled in late evening (second nest in Allison and Cepeda 2009, *op. cit.*).

At 0839 h the lizard was awake but not yet moving, and became active by 0915 h. By 1140 h the nest had been backfilled, and the lizard was resting in the shade of the nearby fence upslope in view of the nest.

At 1140 h, the lizard proceeded to camouflage the nest surface by walking back and forth across, out of and into, the nest site while shuffling feet at each step (noted also in Sherbrooke 2002, *op. cit.*). Camouflaging was complete at 1224 h. At that time, the lizard traveled 1 m upslope from the nest-site, and assumed a standing, upright pose on hind legs until after 1314 h. The posture included two firmly planted hind feet, one somewhat in front of the other, and forelimbs resting on small, herbaceous plants. The posture was striking in both its erectness and its prolonged duration. During this time period, the lizard maintained her two-legged stance without pause. The lizard closed her eyes while an ant (*Pogonomyrmex rugosus*) climbed over her head. The only other movements we observed were periodic head-bobbing and three rapid upper-body twists to look in the direction of sounds from nearby.

We have observed similar postures by two other lizards following nesting events, although neither was as erect, and durations were unrecorded. Sherbrooke (2002, *op. cit.*) reported a lizard "standing high on stretched legs" following the backfilling of a nest cavity and prior to camouflaging activities, but we interpret his account to have been a four-legged stance.

Lizards were weighed, measured, and immediately released in accordance with permit SPR-0294-659 issued by the Texas Parks and Wildlife Department. The Texas Horned Lizard (*P. cornutum*) is designated as a Threatened species in the State of Texas.

Submitted by **PAMELA S. ALLISON**, P.O. Box 60812, Canyon, Texas 79016, USA (e-mail psallison@earthlink.net); and **JOSEPH C. CEPEDA**, West Texas A&M University, Department of Life, Earth, and Environmental Science, P.O. Box 60938, Canyon, Texas 79016, USA (e-mail: jcepeda@mail.wtamu.edu).

PHYLLODACTYLUS UNCTUS (San Lucan Gecko). **REPRODUCTION.** *Phyllodactylus unctus* is restricted to the Cape Region of Baja California and several nearby islands (Grismer 2002. Amphibians and Reptiles of Baja California, Including its Pacific Islands and the Islands in the Sea of Cortés. University of California Press, Berkeley. 399 pp.). Anecdotal information on its reproduction is given in Asplund (1967. Amer. Midl. Nat. 77:462–475) and Grismer (*op. cit.*). The purpose of this note is to report additional information on the reproduction of *P. unctus* from a histological examination of gonadal material from museum specimens.

A sample of 26 *P. unctus*, consisting of 12 adult males (mean snout vent length, SVL = 46.0 mm ± 6.1 SD, range: 39–60 mm), 11 adult females (mean SVL = 45.4 mm ± 3.2 SD, range: 39–48 mm) and 3 presumed neonates (mean SVL = 22.0 mm ± 1.0 SD, range: 21–23 mm) collected 1947, 1959, 1961, 1964, 1975, 1978, were examined from the herpetology collection of the Natural History Museum of Los Angeles County (LACM), Los Angeles, California. The left testis was removed from males and the left ovary was removed from females for histological examination. Tissues were embedded in paraffin and cut into sections of 5 μm. Slides were stained with Harris hematoxylin followed by eosin counterstain. Slides of testes were examined to determine the stage of the spermatogenic cycle. Slides of ovaries were examined for the presence of yolk deposition. Histology slides were deposited in LACM. The following specimens of *P. unctus* were examined from LACM: 3263, 9811, 13971, 13973, 13974, 13976, 13977, 13979–13984, 13987, 13988, 51832, 51833, 122508,127882–127889.

Testes were classified (sample size in parentheses) as to their spermatogenic state: spermiogenesis, the seminiferous tubules are lined with sperm and/or groups of metamorphosing spermatids: March (1), April (7), June (1); regressed, the seminiferous tubules are reduced in size and mainly contain spermatogonia and Sertoli cells: August (3). The smallest reproductively active males (spermiogenesis) each measured 39 mm SVL (LACM 9811, 127883). Ovaries were classified (sample size in parentheses) as to their reproductive state: quiescent: no yolk deposition March (2), August (8), December (1); early yolk deposition: yolk granules in the cytoplasm: April (1). The smallest reproductively active female (yolk deposition) measured 41 mm SVL (LACM 127886). Three presumed neonates were collected in August.

My findings indicate breeding occurs in spring to early summer with a late summer hatching period. This concurs with Asplund (*op. cit.*) who observed *P. unctus* ovaries (N = 6) were quiescent during August and neonates were present in that month. Examination of additional females are needed to elucidate Grismer's (*op. cit.*) observation of gravid August *P. unctus* females. Timing of events in the *P. unctus* reproductive cycle appear similar to those of the congener *P. nocticolus* (formerly *P. xanti*) from southern California (Goldberg 1997. Herpetol. Rev. 28:152–153).

I thank Christine Thacker (LACM) for permission to examine *P. unctus*.

Submitted by **STEPHEN R. GOLDBERG,** Department of Biology, Whittier College, Whittier, California 90608, USA; e-mail: sgoldberg@whittier.edu.

PHYLLODACTYLUS UNCTUS (San Lucan Gecko). **ENDOPARASITES.** *Phyllodactylus unctus* is restricted to the Cape Region of Baja California and several nearby islands (Grismer 2002. Amphibians and Reptiles of Baja California, Including its Pacific Islands and the Islands in the Sea of Cortés. University of California Press, Berkeley. 399 pp.). To our knowledge, there are no reports of helminths from *P. unctus.* The purpose of this note is to establish the initial helminth list for *P. unctus.*

Five individuals of *P. unctus* (mean SVL = 49.8 mm ± 6.9 SD, range = 41–60 mm) from the herpetology collection of the Natural History Museum of Los Angeles County (LACM), Los Angeles, California (LACM 127884–127888) collected in 1978 were examined for endoparasites. The lizards were opened by a midventral incision and the gastrointestinal tract removed and opened longitudinally. The esophagus, stomach, small and large intestines as well as the body cavity were searched for endoparasites using a dissecting microscope. Eight juvenile (11–15 proglottids) cestodes (small intestine, LACM 127885; prevalence, number infected

lizards/number lizards examined × 100 = 20%) were stained in hematoxylin, mounted on slides in Canada balsam and identified as *Oochoristica* sp. Nematodes were cleared in a drop of glycerol, cover-slipped, studied as wet mounts and identified as one female *Thubunaea iguanae* (stomach, LACM 127884; prevalence = 20%) and seven female *Spauligodon oxkutzcabiensis* (large intestine, LACM 127884, 127886, 127887; prevalence = 60%, mean intensity, mean number infected lizards = 2.33 ± 1.5, range = 1–4). Voucher helminths were deposited in the United States National Parasite Collection (USNPC), Beltsville, Maryland as: *Oochoristica* sp. (USNPC 102324), *Spauligodon oxkutzcabiensis* (USNPC 102325), *Thubunaea iguanae* (USNPC 102326).

Species of *Oochoristica* are often identified by number of testes, structure of scolex and ovary as well as sucker size and shape. While structure of the scolex and ovary allow assignment to the genus *Oochoristica*, we were unable to assign the juvenile cestodes to a species. *Spauligodon oxkutzcabiensis* has been reported from lizards in Mexico, Central and South America (see Goldberg and Bursey 2009. Herpetol. Rev. 40:224). *Phyllodactylus unctus* is the fourth species of gecko reported to harbor *Spauligodon oxkutzcabiensis* and represents a new host record for this nematode. Baja California Sur is a new locality record. *Thubunaea iguanae* has been reported in a variety of lizards from the southwestern United States and Mexico (Telford 1965. Jpn. J. Exp. Med. 35:111–114; Goldberg et al. 2009. Herpetol. Rev. 40:85) as well as colubrid snakes (Goldberg and Bursey 2001. Bull. South. California Acad. Sci. 100:109–116). *Phyllodactylus unctus* represents a new host record for *Thubunaea iguanae*.

We thank Christine Thacker (LACM) for permission to examine *P. unctus* and Cecilia Nava (Whittier College) for assistance with dissections.

BURSEY,** Pennsylvania State University, Shenango Campus, Department of Biology, Sharon, Pennsylvania 16146, USA (e-mail: cxb13@psu.edu).

PHYMATURUS FLAGELLIFER (Matuasto). **BRUMATION BEHAVIOR.** *Phymaturus flagellifer* is an endemic lizard of the Andes Mountains, ranging from 32º to 37ºS latitude (Lamborot and Navarro 1984. Herpetologica 40:258–264). During the breeding season (October to March), hierarchy reproductive systems have been described with one male congregating numerous females on large stones, while in sites with smaller stones, only lone couples or solitary individuals are observed (Habit and Ortiz 1994. Bol. Soc. Biol. Concepción, Chile 65:149–152; Habit and Ortiz 1996. *In* Peáur [ed.], Herpetología Neotropical, pp. 141–154). There is almost no information regarding brumation behavior in this species within its extreme environment (areas covered with snow for six to seven months).

From 19 to 23 May 2008, while performing fieldwork in the Andes Mountains (Laguna del Maule (35.984074°S, 70.532293°W; WGS84; 2184 m elev., Maule Administrative Region, Chile), we found a group of 37 *P. flagellifer* in brumation underneath a stone (1 m × 40 cm; 40 cm depth) resting on a substrate of volcanic sand. The group was composed of 4 males, 18 females, 11 juveniles, and 5 neonates.

Our observation suggests that aggregation behavior in *P. flagellifer* is likely important in enabling this species to survive harsh winter conditions. Brumation behavior of reptiles at high elevations of the Andes is poorly known and this report contributes to the limited knowledge concerning the life history of *P. flagellifer*.

PODARCIS SICULUS (Italian Wall Lizard). **PREDATION.** *Podarcis siculus campestris* is a medium-sized Italian lacertid lizard that has been introduced into at least four U.S. states (New York, Pennsylvania, and Kansas—Burke and Deichsel 2008. *In* Mitchell et al. [eds.], Urban Herpetology, pp. 347–353. SSAR Herpetol. Conserv. 3, Salt Lake City, Utah; New Jersey—Burke, unpubl. data). Here we report on the predation of this introduced species by a native species.

At least three different American Kestrels (*Falco sparverius)* were observed feeding on Italian Wall Lizards (*P. siculus campestris*) in New York City. One *F. sparverius* was an adult (sex undetermined) at a nest on Broadway between 68th and 69th streets, Manhattan, observed clutching a lizard in the summer of 2006. Two male *F. sparverius*, one at East 75th Street, Manhattan and another in Sunnyside, Queens, were observed bringing *P. siculus campestris* to their mates and young. Although observations were not systematic in any of these cases, the East 75th Street male was observed with at least six different lizards between 8 June and 6 July, 2009 and the Queens male was observed with at least five different lizards during the spring of 2009, and five lizards in spring of 2008. A photograph, (Fig. 1) taken 4 July 2009 at the East 75th Street nest, is clearly that of a gravid female *P. siculus campestris* being passed from an adult male *F. sparverius* to a juvenile. Male-biased foraging is not surprising because female *F. sparverius* are largely dependent on their mates for provisioning during the last few weeks of incubation and until hatchlings are about ten days old (Smallwood and Bird 2002. Birds of North America Online http://bna.birds.cornell.edu/bna/species/602).

Although there may be others, we are aware of only five *Podarcis siculus* populations in the area: Queens College (Queens), Bronx Botanical Gardens and Pelham Bay Park (Bronx), Washington Cemetery (Brooklyn), and Baker Field (Manhattan). These populations are a minimum of 13 km from any of these nests, thus we suspect that there may be other *Podarcis* populations closer to the nests.

Falco sparverius are common inhabitants of urban, suburban, and rural habitats of North America and South America and feed on a wide variety of small vertebrates and invertebrates (Smallwood and Bird, *op. cit.*). *Falco sparverius* have not been previously

FIG. 1. Male kestrel passes *Podarcis* lizard to young. Photograph by Deborah Allen.

reported to predate *Podarcis*, but they have been reported to consume *Anolis* lizards (Adolph and Roughgarden 1983 Oecologia 56: 313–317) and *Sceloporus occidentalis, S. graciosus*, and *Elgaria coerulea* (Balgooyen 1976 Univ. California Publ. Zool. 103:1–87). The natural range of *P. siculus* is restricted almost entirely to Italy. There *Podarcis* spp. are predated by *Falco tinnunculus* (Eurasian Kestrel) (Martín and López 1990. Smithson. Herpetol. Info. Serv. No. 82, pp. 1–43; Costantini et al. 2005. Behaviour 142:1409–1421), but *P. siculus* has not specifically been positively identified as *Falco* prey.

This is the second report of predation by a native predator on *Podarcis* in New York (see Mendyk 2007 Herpetol. Rev. 38:82); introduced *Podarcis* in Kansas are predated by Great Plains Skinks (*Eumeces obsoletus*) and Blue Jays (*Cyanocitta cristata*) (Burke and Deichsel, *op. cit.*). Should populations of *Podarcis siculus* expand, it is likely the list of species that prey on this non-native lizard will increase.

Box 1452 Peter Stuyvesant Station, New York 10009, USA (e-mail: DAllenyc@earthlink.net); **BEN CACACE**, 425 E. 74th St. Apt. 6E, New York, New York 10021, USA (e-mail: bcacace@gmail.com); **ROB CICCHETTI**, 155W 68th St., Manhattan, New York 10023, USA (e-mail: rob.cicchetti@yahoo.com); **ERIC COHEN**, 4209 47th Avenue, Apartment 6A, Sunnyside, New York 11104, USA (e-mail: ericmarccohen@gmail.com); and **ROBERT DECANDIDO**, 1831 Fowler Avenue, The Bronx, New York 10462, USA (e-mail: rdcny@earthlink.net).

SCELOPORUS CLARKII (Clark's Spiny Lizard). **AQUATIC BEHAVIOR**. Several terrestrial lizard species have been observed attempting to escape potential predators by submerging their bodies underwater, including *Cnemidophorus sexlineatus* (Dillon and Baldauf 1945. Copeia 1945:174; Trauth et al. 1996. Herpetol. Rev. 27:20), *Crotaphytus collaris* (Burt and Hoyle 1934. Trans. Kansas Acad. Sci. 37:193–216), and *Scincella lateralis* (Akin and Townsend 1998. Herpetol. Rev. 19:43). Herein, we report an observation of similar behavior in *Sceloporus clarkii*, a non-aquatic, typically arboreal, lizard.

On 30 June 2008 at 0823 h, we observed an adult *S. clarkii* sprinting across bedrock in the bottom of a deeply-incised canyon in the Rincon Mountains east of Tucson, Arizona (32.16271°N, 110.69902°W, WGS84). The lizard disappeared under a rock ledge below us, and moments later we heard a splash. We found the lizard completely submerged in a shallow pool of water with a gravel-lined bottom (ca. 60 mm deep) under the rock ledge. The lizard remained underwater for approximately three minutes, lifted its head out of the water and took a breath, and then submerged its head and body completely for several more minutes. The lizard then lifted its snout and eyes above the surface of the water and remained in this position for more than 10 minutes, after which we stopped observing to avoid disturbing the lizard any more than necessary. The use of water as a refuge from predators has not been widely reported for terrestrial lizards, probably due to the thermodynamic costs associated with submergence. In this case, however, the lizard may have tolerated prolonged submergence because the water temperature was relatively high due to elevated ambient temperatures (>32°C) and the shallow depth of the pool.

FIG. 1. Adult *Sceloporus clarkii* partially submerged in shallow canyon pool in southern Arizona, USA.

Submitted by **ERIN R. ZYLSTRA**, School of Natural Resources, University of Arizona, 325 Biological Sciences East, Tucson, Arizona, USA (email: erinzylstra@gmail.com); and **BRUCE D. WEISE**, 6251 E. 35th St., Tucson, Arizona 85711, USA.

STENOCERCUS DOELLOJURADOI **(NCN). CLUTCH SIZE**. *Stenocercus doellojuradoi* (Tropiduridae) is a Chaco endemic species of Argentina, and regarded as a vulnerable species associated with Chaco forests (Pelegrin et al. 2006. Herpetozoa 19(1/2):85–

86). The Chaco ecoregion is a vast woodland that covers more than 1.2 million km^2, including portions of Argentina, Bolivia, and Paraguay, ranging from tropical (18ºS) to subtropical (31ºS) latitudes. The southernmost portion of the Chaco (Dry Chaco) is characterized by having lower temperatures and rainfall (Bucher 1982. Ecological Studies 42:48–79). Although *S. doellojuradoi* is a common species within its limited distribution, its natural story has been poorly studied, and there is no available information on its reproductive biology. In the context of an ecological study on lizard assemblages in the Dry Chaco of Córdoba, Argentina (30.37ºS, 65.43°W), we recorded females with oviductal eggs in November, January, and February; one female (SVL = 77 mm, 18 g) from November was found to be carrying six eggs (mean length ± SD = 13.33 ± 1.37 mm). This is the first report of reproductive data for this species.

TROPIDURUS HISPIDUS (Calango). **PREY**. Lizard species of the widely distributed South American genus *Tropidurus* (Rodrigues 1987. Arq. Zool., São Paulo 31:105–230) are sit-and-wait ambush predators that feed predominantly on arthropods (Fialho et al. 2000. J. Herpetol. 34:325–330; Van Sluys 1993. J. Herpetol. 27:347–351; Vitt 1991. J. Herpetol. 25:79–90). Some species also are known to prey on vertebrates such as mammals, lizards, and frogs (Gasparini and Peloso 2007. Herpetol. Rev. 38:464). Saurophagy is already recorded for species of *Tropidurus*, be these conspecifics (Araújo 1987. Rev. Brasil. Biol. 51:857–865; Dias and Rocha 2004. Herpetol. Rev. 35:398–399; Kiefer and Sazima 2002. Herpetol. Rev. 33:136; Kohlsdorf et al. 2004. Herpetol. Rev. 35:398) or other lizard species (Galdino and Van Sluys 2004. Herpetol. Rev. 35:173; Kiefer 1998. Herpetol. Rev. 29:41; Kiefer et al. 2006. Herpetol. Rev. 37:475–476; Teixeira and Giovanelli 1999. Rev. Brasil. Biol. 59:11–18). *Tropidurus hispidus* has a wide distribution and is locally abundant (Rodrigues, *op. cit.*). This species is considered a generalist, its diet consisting primarily of arthropods (Vitt and Carvalho 1995. Copeia 1995:305–329), although there are records of predation on frogs (Vitt et al. 1996. J. Trop. Ecol. 12:81–101) and an attempt of predation on the gekkonid lizard *Hemidactylus palaichthus* (Rojas-Runjaic et al. 2006. Herpetol. Rev. 37:474). Here we present two instances of saurophagy and one of anurophagy in a coastal population of *T. hispidus*. Several individuals of this species were caught in April and May 2006, during a study carried out in a restinga habitat (characterized by sand dunes and sparse vegetation) on the beach of Panaquatira (2.561944°S, 44.054167°W), São José de Ribamar municipality, State of Maranhão, Brazil. One hundred and eleven specimens were dissected for gut content investigation; these specimens and their prey are in the Museu de Zoologia "Prof. Dr. Adão José Cardoso" (ZUEC), Universidade Estadual de Campinas. An adult male (ZUEC REP 03193; 85.3 mm SVL; 25 g) contained a partially digested juvenile (ca. 50.66 mm SVL) teiid lizard *Cnemidophurus ocellifer*; another adult male (ZUEC REP 03194; 83.9 mm SVL; 19 g) contained one adult (ca. 48 mm SVL) of the gymnophtalmid lizard *Colobosaura modesta*, and a female (ZUEC REP 03195; 80.4 mm SVL; 15.5 g) contained a skull bone (12.14 mm) of an unidentified frog. The two lizard prey items were partly digested, however, the head to the anterior part of the tail remained nearly intact. Further, the heads of each lizard were positioned in the anterior part of the stomach, thus indicating that both lizards were probably swallowed tail-first. *Cnemidophorus ocellifer* and *Colobosaura modesta* are active foragers (Bergallo and Rocha 1994. Austral. J. Ecol. 19:72–75; Rocha 1994. *In* Nascimento et al. [eds.], Herpetologia no Brasil 1, pp. 39–57. PUC-MG: Fundação Biodiversitas: Fundação Ezequiel, Belo Horizonte), whereas *T. hispidus* is a territorial sit-and-wait predator (Van Sluys et al. 2004. J. Herpetol. 38:606–611; Vitt and Carvalho, *op. cit.*). Active foragers are on the move and thus are exposed to risk of predation by sit-and-wait predators (Pianka 1986. Ecology and Natural History of Desert Lizards. Princeton University Press, Princeton, New Jersey. 208 pp.). Our observations on the positions of the two lizards in the stomachs of each *T. hispidus*, in addition to a record of a *C. ocellifer* also ingested tail-first by the conspecific *T. torquatus* (Kokubum and Lemos 2004. Herpetol. Rev. 35: 270–271) indicate that all three lizard prey were chased down by the predator and swallowed as they were caught. The occurrence of lizards among the prey items sampled was of low frequency (1.8%), which suggests that saurophagy in *T. hispidus* is opportunistic. Predation on frogs by *T. hispidus* (0.9%) is even lower in our sample and also seems to be opportunistic as recorded for other populations of the same species (Vitt et al., *op. cit.*). Predation on *C. ocellifer* and *C. modesta* presented here are the first records of saurophagy for *T. hispidus*.

We thank I. Sazima for critically reading this manuscript and Jerriane O. Gomes for confirming the identification of the prey items. The permit for collecting lizards was given by IBAMA (process 02010000071/07-01).

COSTA,** Departamento de Parasitologia, Instituto de Biologia, Universidade Estadual de Campinas, 13083-970, Campinas, São Paulo, Brazil (e-mail: joaoclcosta@yahoo.com.br); **PAULO R. MANZANI,** Departamento de Zoologia, Instituto de Biologia, Universidade Estadual de Campinas, 13083-970, Campinas, São Paulo, Brazil (e-mail: manzani@unicamp.br); **MARIA P. DE L. BRITO** (e-mail: mplbrito@hotmail.com), and **ADRIANO O. MACIEL**, Museu Paraense Emílio Goeldi, 66077-830, Belém, Pará, Brazil (e-mail: aombiologo@yahoo.com.br).

TUPINAMBIS LONGILINEUS (NCN). **ENDOPARASITES.** *Tupinambis longilineus* is the smallest and least known species of its genus, with distribution records for only four localities documented from the Brazilian states of Amazonas, Pará, Rondônia and Mato Grosso (Costa et al. 2008. Check List 4[3]:267–268). No records of parasites are published for this species. Here, we report the nematode *Physaloptera retusa* infecting the stomach of an adult male *T. longilineus* (MZUFV 564; 230 mm SVL) from Aripuanã, Mato Grosso State, Brazil (10.16°S, 59.47°W; datum: WGS84) housed in the herpetological collection of Museu de Zoologia João Moojen, Universidade Federal de Viçosa, municipality of Viçosa, Minas Gerais State, Brazil. Six adult *P. retusa* were recovered while we conducted a dietary study. The nematodes were deposited at Coleção Helmintológica de Referência do Instituto de Biociências da UNESP-Botucatu (CHIBB 4006).

Physaloptera retusa is one of the most common parasites of Neotropical herpetofauna, known to infect more than 60 hosts, including *Tupinambis teguixin* and *T. rufescens* (Bursey et al. 2007. Comp. Parasitol. 74:108–140). *T. longilineus* is a new host record for *P. retusa* and the state of Mato Grosso represents a new locality record for this parasite.

We thank Energética Águas da Pedra S.A. for financial support of the fieldwork in Aripuanã and IBAMA for granting collection permits (029/2006-COFAN and 50/2007-SUPES/MT, process # 02001.003069/2004-42). The parasitological study had financial support by FAPESP (processes 04/03628-1, 06/59692-5 and 08/05417-7) and RWA thanks CAPES for a grant.

SILVA,** Departamento de Parasitologia, Instituto de Biociências, UNESP, Distrito de Rubião Jr., CEP 18618-000, Botucatu, SP, Brazil; **HENRIQUE CALDEIRA COSTA, VINÍCIUS DE AVELAR SÃO PEDRO,** and **RENATO NEVES FEIO**, Museu de Zoologia João Moojen, Universidade Federal de Viçosa, Vila Giannett 32, CEP 36571-000, Viçosa, MG, Brazil.

TYMPANOCRYPTIS LINEATA (Lined Earless Dragon). **ENDOPARASITES.** *Tympanocryptis lineata* is known from eastern and southeastern Western Australia to the western slopes of New South Wales and southern Victoria where it occurs in a wide variety of terrestrial habitats (Cogger 2000. Reptiles and Amphibians of Australia, 6th ed. Ralph Curtis Books, Sanibel Island, Florida. 808 pp.). We know of no reports of endoparasites from this species. The purpose of this paper is to establish the initial helminth list for *T. lineata*.

Seven individuals of *T. lineata* (mean SVL = 53.3 mm ± 4.0 SD, range = 48–61 mm) were borrowed from the herpetology collection of the Natural History Museum of Los Angeles County (LACM), Los Angeles, California and examined for helminths. Three were collected between 28.9500°S to 32.5500°S and 134.3167°E to 137.2167°E; WGS 84, elev. ca 200 m, in South Australia during 1966 and 1968 (LACM 55380–55381, 57944) and four were collected between 18.3833°S to 31.9833°S and 125.7333°E to 125.8500°E; WGS 84, elev. 125–400 m, in Western Australia during 1966–1967 (LACM 55382–55383, 55385–55386). The body cavity was opened by a longitudinal incision and the large and small intestines were removed and examined using a dissecting microscope. Stomachs were not available for examination. Only cestodes were present, which were regressively stained in hematoxylin, mounted in Canada balsam, studied under a compound microscope and identified as *Oochoristica piankai*.

One, one, and two individuals of *O. piankai* were found in the small intestines of LACM 55381, 55382, and 55385, respectively. Prevalence (number infected lizards/number examined lizards × 100) was 43%. Mean intensity (mean number parasites) was 1.3 ± 0.57 SD, range = 1–2.

Voucher endoparasites were deposited in the United States National Parasite Collection (USNPC), Beltsville, Maryland as *Oochoristica piankai* (USNPC 102139, 102140).

Oochoristica piankai was originally described from the small intestines of *Moloch horridus* by Bursey et al. (1996. J. Helminthol. Soc. Washington 63:215–221). It has subsequently been reported in *Ctenophorus fordi*, *C. isolepis*, and *C. reticulatus* (Goldberg et al. 2000. Comp. Parasitol. 67:109–114) and *Nephrurus laevissimus* (Bursey and Goldberg 1999. J. Helminthol. Soc. Washington 66:175–179). The life cycle of *O. piankai* has not been studied, but Conn (1985. J. Parasitol. 71:10–16) reported beetles (*Tribolium*) acted as intermediate hosts for the congener *Oochoristica anolis*. *Tympanocryptis lineata* represents a new host record for *Oochoristica piankai*.

We thank C. Thacker (LACM) for permission to examine specimens and C. Nava (Whittier College) for assistance with dissections.

Submitted by **STEPHEN R. GOLDBERG,** Department of Biology, Whittier College, Whittier, California 90608, USA (e-mail: sgoldberg@whittier.edu); and **CHARLES R. BURSEY,** Department of Biology, Pennsylvania State University, Shenango Campus, Sharon, Pennsylvania 16146 (e-mail: cxb@psu.edu).

SQUAMATA — SNAKES

AGKISTRODON PISCIVORUS (Cottonmouth). **ECTOPARASITE**. Many internal parasites have been reported for *Agkistrodon piscivorus* (Gloyd and Conant 1990. Snakes of the *Agkistrodon* Complex: A Monographic Review. Society for the Study of Amphibians and Reptiles, Oxford, Ohio. 614 pp.). However, no data on ectoparasites from wild-caught individuals are available, with the exception of reports of blood feeding by mosquitoes (Burkett-Cadena et al. 2008. Am. J. Trop. Med. Hyg. 79:809–815). On 31 July 2008, 2020 h CST, we captured a large adult male *A. piscivorus* (SVL = 83.8 cm; 595 g) in a small creek at Tuskegee National Forest, Macon County, Alabama, USA (32.434486ºN, 85.643901ºW; WGS 84). While restraining (tubing) the snake for processing, we noticed a leech attached to the posterior one-third of the snake's dorsum. The leech was placed in water in a plastic vial and was later keyed (by EB) as *Placobdella ornata*, a leech that commonly parasitizes turtles (Siddal and Gaffney 2004. J. Parasitol. 90:1186–1188). We could not confirm that this leech had obtained a blood meal from the snake, so the attachment may have been only phoretic (e.g., for dispersal).

This observation was made while conducting research funded by NIH grant # R01-A149724 to T. Unnasch under ADCNR Permit # 4268, and NSF Minority Postdoctoral Fellowship (DBI# 0706856) to EB.

Submitted by **SEAN P. GRAHAM** (e-mail: grahasp@auburn.edu), **ELIZABETH BORDA**, and **MATT R. CONNELL**, Department of Biological Sciences, 331 Funchess Hall, Auburn University, Alabama 36849, USA.

AGKISTRODON PISCIVORUS (Cottonmouth). **DIET**. On 19 April 2008, at 1647 h at an oxbow pond in Tuskegee National Forest, Macon County, Alabama, USA (32.43875203°N, 85.63422342°W, datum: WGS 84), we captured an adult male *Agksitrodon piscivorus* (SVL = 75.7 cm) with a pronounced bulge in its posterior half. We palpated the snake and discovered the bulge to be a partially digested subadult *Agkistrodon contortrix* (Copperhead). *Agkistrodon piscivorus* has one of the broadest diets of any known snake, with >100 species of invertebrates, fish, amphib-

ians, reptiles, mammals, and birds listed as prey (Ernst and Ernst 2003. Snakes of the Unites States and Canada. Smithsonian Press, Washington, D.C., 668 pp.). However, this is the first record of an *A. contortrix* being consumed by an *A. piscivorus*. A photograph of both snakes was deposited in the AUM digital database (AHAP-D 42). The *A. piscivorus* was released at its point of capture and the palpated copperhead was left next to the cottonmouth.

We thank the C. Guyer for comments on this note. This observation was made while conducting research funded by NIH grant R01-A149724 to T. Unnasch under ADCNR Permit 4268.

Submitted by **SEAN P. GRAHAM** (e-mail: grahasp@auburn.edu), **MATT R. CONNELL**, and **KATHERINE M. GRAY**, Auburn University, Department of Biological Sciences, 331 Funchess Hall, Auburn, Alabama 36849, USA.

BOTHROPS INSULARIS (Golden Lancehead). **MAXIMUM LENGTH.** *Bothrops insularis* is a viperid endemic to Queimada Grande Island (0.43 km^2), approximately 35 km from the coast of São Paulo State, Brazil (Amaral 1922. Mem. Inst. Butantan 1:39–44). *Bothrops insularis* is considered critically endangered (IUCN 2007. Red List of Threatened Species; Machado et al. 2005. Lista da Fauna Brasileira Ameaçada de Extinção. Fundação Biodiversitas. Belo Horizonte. 157 pp.) and may be declining (Martins et al. 2008. South Am. J. Herpetol. 3:168–174). In December 1995, one of us (OAVM) found a female *B. insularis* that weighed 391 g and measured 1093 mm total length (SVL = 950 mm; tail length = 143 mm). In December 2007 we found a male that weighed 185 g and measured 912 mm total length (SVL = 775 mm; tail length = 137 mm). Of the 520 individuals observed over 15 years of fieldwork on the island, the specimens above represent the largest individuals of each sex. The size of these snakes also exceeds the length of all preserved specimens (250 males and 400 females) from the herpetological collection of the Instituto Butantan.

In 1920, Amaral (1922) collected a female *B. insularis* (IB 1900) that reportedly measured 1180 mm in total length. The current total length of this specimen is 992 mm (SVL = 882 mm; tail length = 110 mm). When re-measured, we found other specimens cited by Amaral (1922) to be smaller than originally reported. This incongruence in lengths suggests that the specimens either shrunk substantially over time or were measured incorrectly at the time of collection. Regardless of the status of specimens collected by Amaral (1922), the lengths reported here likely represent the maximum sizes currently attained by male and female *B. insularis* in the field.

We thank Valdir Germano from Herpetological Collection of Instituto Butantan, and J. D. Willson for suggestions on the manuscript. Conselho Nacional de Pesquisa e Desenvolvimento (CNPq) and Fundação de Amparo a Pesquisa do Estado de São Paulo (Fapesp) provide financial support.

CONOPSIS LINEATA (Large-nosed Earthsnake). **LITTER SIZE.** Little is known about reproduction of *Conopsis lineata* (Fitch 1970. Univ. Kansas Mus. Nat. Hist. Misc. Publ. 52:1–214). Anecdotal information indicates that litter size ranges from 2–3 for individuals from Hidalgo, Mexico (Goyenechea 2003. Herpetol. Rev. 34:63), 3–5 for individuals from Veracruz, Mexico (Greer 1966. Copeia 1966:371–373), and 2–6 for individuals from Mexico City (Uribe-Peña et al. 1999. Anfibios y Reptiles de Las Serranías del Distrito Federal. Universidad Nacional Autónoma de México. 118 pp.). On 14 June 2008 we found a dead gravid female *C. lineata* on the road from Municipality of Mineral de la Reforma, Mexico (20.09011ºN, 98.71064ºW, datum: WGS84; elev. 2431 m; xerophytic vegetation). The female measured 225 mm SVL, weighed 17. 5 g, had a litter size of seven well-developed embryos (stage 40). Measurements of embryos (mean ± SE, range) are as follows— mass: 0.78 ± 0.02 g, 0.70–0.84; SVL: 64.5 ± 7.5 mm, 34.6–77.6; total length: 82.4 ± 7.9 mm, 51.4–101.1.

We thank A. Leyte-Manrique for his logistic help. This study was supported by the projects SEP-PROMEP-1103.5/03/1130, CONACYT-S 52552-Q, and FOMIX-CONACYT-43761

CORALLUS HORTULANUS (Amazon Tree Boa). **TIMING OF REPRODUCTION**. Observations of snakes giving birth in nature are rarely published and little is known about timing of reproduction in most tropical snake species (Greene 1997. Snakes the Evolution of Mystery in Nature. Univ. California Press, Los Angeles. 351 pp.). *Corallus hortulanus* are known to give birth to 3–24 newborns (total length: 282–455 mm) from January to June and litter size is positively related to female SVL (Pizzatto and Marques 2007. S. Am. J. Herpetol. 2:107–122).

On 17 November 2008, at 2040 h, in Parque Nacional dos Campos Amazônicos, Amazonas state, Brazil (8.05°S, 61.58°W; datum WGS84; elev. ca. 100 m), we observed a female *C. hortulanus* (SVL = 1040 mm; tail length = 290 mm) on the ground and four newborns (SVL: 462, 465, 460, 467 mm; tail lengths: 121, 122, 119, and 126 mm) on vegetation (40–250 cm high) nearby. The specimens were photographed, measured, and immediately released. This observation extends the known birthing season for the species and possibly suggests year-round reproduction or geographic variation in timing of reproduction for *C. hortulanus* in Brazil.

CROTALUS DURISSUS (South American Rattlesnake). **ARBOREAL HABITAT USE.** *Crotalus durissus* is the most widespread rattlesnake species and is the only one to reach South America. It occurs in all mainland countries except Ecuador and Chile, with a discontinuous distribution from Colombia to Argentina (Campbell and Lamar 2004. Venomous Reptiles of the Western Hemisphere.

FIG. 1. An adult *Crotalus durissus* using an arboreal resting site in small trees at the edge of Cerrado canopy woodland (*cerradão*) in Volta Grande Environmental Station, southeastern Brazil.

Cornell Univ. Press, Ithaca, New York. 870 pp.). *Crotalus durissus* inhabits open habitats (Campbell and Lamar, *op. cit.*; Wüster et al. 2005. Mol. Ecol. 14:1095–1108), and also colonizes anthropogenically deforested areas (Bastos et al. 2005. Rev. Bras. Zool. 22:812–815; Sazima and Haddad 1992. *In* Morellato [ed.], História Natural da Serra do Japi, pp. 212–236. Editora da UNICAMP e FAPESP, Campinas). It is primarily crepuscular or nocturnal and terrestrial, using holes on the ground as diurnal shelters (Sazima and Haddad, *op. cit.*).

At 1500 h on 11 January 2006, we observed arboreal habitat use by an adult *C. durissus* at Volta Grande Environmental Station (20.024917°S, 48.235750°W, datum: SAD69), municipality of Conceição das Alagoas, state of Minas Gerais, southeastern Brazil. The rattlesnake was found coiled and stationary on branches of a small tree, at the edge of a Cerrado canopy woodland (*cerradão*), about 2 m above ground (Fig. 1).

Campbell and Lamar (*op. cit.*) reviewed published reports of *Crotalus* species resting, foraging, or feeding above ground. They reported arboreal habitat use in several species, including *C. adamanteus*, *C. catalinensis*, *C. enyo cerralvensis*, *C. horridus*, *C. lepidus klauberi*, *C. molossus*, *C. oreganus helleri*, *C. ruber lorenzoensis*, and *C. willardi willardi*, sometimes up to 9 m high. By resting above the ground, a snake may be less vulnerable to terrestrial predators (Martins 1993. Herpetol. Rev. 24:83–84). Another hypothesis for the behavior is that the snake was thermoregulating in the sun-shade mosaic formed by vegetation, a behavior commonly observed in the sympatric pitviper *Bothrops jararaca* (Sazima 1988. Mem. Inst. But. 50:83–99).

We thank Companhia Energética de Minas Gerais (CEMIG) for the financial support to JSD and John D. Willson for valuable suggestions.

CROTALUS OREGANUS LUTOSUS (Great Basin Rattlesnake). **ELEVATION**. On 18 June 2007 we observed a *Crotalus oreganus lutosus* at an elevation of 3962 m near the summit of Wheeler Peak, Great Basin National Park, White Pine County, Nevada, USA (38.986°N, 114.314°W, datum: WGS1984). A color slide of the snake was cataloged as a photo voucher (BYU 49442; verified by Jack Sites) (Fig. 1). The snake was found well above the treeline, in rocky, talus, fell-field habitat. It rattled upon approach and crawled over a snowfield. In July 2000 we observed three *C. o. lutosus* at 3090 m in south-facing, rocky, low sagebrush (*Artemisia arbuscula*) steppe habitat, in Great Basin National Park. *Crotalus o. lutosus* was previously reported at a maximum elevation of 3063 m (Klauber 1972. Rattlesnakes: Their Habits, Life Histories, and Influence on Mankind. Volume I. 2nd ed. Univ. California Press, Berkeley, 740 pp.). To our knowledge, these observations represent the maximum elevations reported for *C. o. lutosus*. Wheeler Peak is the second highest point in the Great Basin, at 3982 m, suggesting that *C. o. lutosus* may occur at all elevations within its range.

FIG. 1. *Crotalus oreganus lutosus* (BYU 49442) crawling through talus and snowfields at 3962 m in Great Basin National Park, White Pine County, Nevada, USA.

DIADOPHIS PUNCTATUS PUNCTATUS (Southern Ring-necked Snake). **DIET.** *Diadophis punctatus* eats a variety of small animals, including insects, slugs, earthworms, snakes, lizards, anurans and salamanders (Ernst and Ernst 2003. Snakes of the United States and Canada. Smithsonian Institution Press, Washington D.C. 668 pp.). In addition to the salamandrid *Taricha torosa*, plethodontid salamanders in the genera *Aneides*, *Batrachoseps*, *Desmognathus*,

Eurycea, and *Plethodon* have been reported as prey of *Diadophis*, as well as salamander eggs. Specifically, *Eurycea bislineata*, *E. cirrigera*, *E. longicauda*, and *E. quadridigitata* are known to be constituents of the diet of *D. punctatus*. Uhler et al. (1939. Trans. N. Am. Wildl. Conf. 4:605–622) reported that salamanders made up 80% by volume of the diet of Virginia *D. punctatus*. We report a novel species of *Eurycea*, *E. lucifuga* (Cave Salamander), in the diet of *D. punctatus*.

At 1545 h on 25 April 2009, one of us (KTN) found an adult ringneck snake crawling ~2 m inside the entrance to Pettijohn's Cave on Pigeon Mountain, Walker Co., Georgia, USA (34.663947°N, 85.363547°W; WGS 84). At 1610 h, the snake regurgitated an adult *E. lucifuga* weighing 3.37 g and measuring 67 mm SVL (total length = 157 mm), swallowed headfirst. At least 15 live *E. lucifuga* had been observed in crevices and on rock faces immediately surrounding the cave entrance, as well as at least two *Plethodon petraeus*, so presumably these salamanders represent a fairly abundant and predictable source of food.

D. punctatus are known to occasionally enter moist caves (Ernst and Ernst, *op. cit.)* and locate their prey by scent (Lancaster and Wise 1996. Herpetologica 52:98–108). Venom (Taub 1967. Bull. Am. Mus. Nat. Hist. 138:1–50; O'Donnell et al. 2007. Toxicon. 50:810–815) may enable *D. punctatus* to overcome salamander defensive behaviors (Brodie Jr 1977. Copeia. 1977:523–535). Cave salamanders have been suggested to be top predators in many cave communities (Petranka 1998. Salamanders of the United States and Canada. Smithsonian Institution Press, Washington, D.C. 587 pp.), so the addition of a higher trophic level is significant, especially since *E. lucifuga* are reported to depredate *Plethodon glutinosus*, another predator (Peck and Richardson 1976. Annales de Speleologie 31:175–182).

DINODON RUFOZONATUM RUFOZONATUM (Asian Kingsnake). **DIET, OVOPHAGY**. Recorded prey items of *Dinodon rufozonatum rufozonatum* include a nestling bird (species unknown), anurans (*Bufo bankorensis*, *B. melanostictus*, *Rana adenopleura*), skinks, snakes (including *Sinonatrix percarinata*), and a beetle (Lee and Lue 1996. Biol. Bull. Natl. Taiwan Normal Univ. 31:119–124; Lee and Lue 1996. J. Taiwan Mus. 49:137–138; Lin et al. 1995. Newsletter of Wildlifers 3:19–21; Norval and Mao 2004. Herpetol. Rev. 35:65; Mao, unpubl. data).

On 20 April 2008, at 2010 h, a juvenile female *D. r. rufozonatum* (SVL = 462 mm; tail length = 122 mm; 33.8 g) was found at the edge of a field that had been tilled and left to lay fallow in Santzepu, Sheishan District, Chiayi County, Taiwan (23.4308667°N, 120.4845333°E, datum: WGS84; elev. 64 m). Palpation revealed an object in the stomach and the snake was induced to regurgitate the object; a reptilian egg (length = 9.3 mm; width = 5.3 mm; 0.1 g). Two days later, the remains of four additional eggs were found in the excrement of the snake. *Plestiodon* (= *Eumeces*) *elegans* and *Takydromus kuhnei* are very common lizards in this area. Eggs of *P. elegans* are larger (mean length ± SD = 15.25 ± 1.89 mm; width = 10 ± 0.82 mm; 1.25 g; Mao et al. 2008. Sauria 30:51–54) than those of *T. kuhnei* (mean length = 10.25 ± 0.69 mm; width = 5.93 ± 0.23 mm; 0.23 ± 0.05 g). Thus, based on the size, we believe that the eggs retrieved from the *D. r. rufozonatum* were those of *T. kuhnei*. The fact that no other prey remains were found leads us to believe the snake preyed only on the eggs. To our knowledge this is the first report of *D. r. rufozonatum* predation on reptilian eggs.

DRYMARCHON COUPERI (Eastern Indigo Snake). **LONG-DISTANCE INTERPOPULATION MOVEMENT**. *Drymarchon couperi* was listed by the U.S. Fish and Wildlife Service (USFWS) as threatened in 1978 due to population declines caused primarily by habitat loss and habitat degradation (USFWS 1982. Eastern Indigo Snake Recovery Plan. U.S. Fish and Wildlife Service, Atlanta, Georgia. 23 pp.). In the northern part of their range (northern Florida and the Coastal Plain of southern Georgia, USA), adult *D. couperi* rely on Gopher Tortoise (*Gopherus polyphemus*) burrows for winter dens (Diemer and Speake 1983. J. Herpetol. 17:256–264; Stevenson et al. 2009. Herpetol. Cons. Biol. 4:30–42). In southeastern Georgia, *D. couperi* populations are typically restricted to sites where intact xeric sandhill habitats supporting *G. polyphemus* occur contiguous with extensive areas of poorly-drained or mesic upland habitats (pine flatwoods, mixed pine-oak forests, slope forests) and wetlands (Diemer and Speake 1981. *In* Odum and Guthrie [eds.], Proc. Nongame and Endangered Wildlife Symposium, pp. 52–61. Georgia Dept. Nat. Resources, Game and Fish Div. Tech. Bull.WL–5; Diemer and Speake 1983, *op. cit.*). Although *D. couperi* may use sandhill habitats throughout the year, during their period of greatest surface activity and movements (April–October) mesic habitats and wetlands are used frequently, particularly by foraging snakes (Hyslop 2007. Movements, Habitat Use, and Survival of the Threatened Eastern Indigo Snake [*Drymarchon couperi*] in Georgia. Unpubl. dissertation, University of Georgia, Athens). Adult *D. couperi* may range 2–6 km from their overwintering sites and typically exhibit overwintering site fidelity by returning to the same sandhills, commonly using some of the same tortoise burrows in successive years (Hyslop et al. 2009. Copeia 2009:460–466; Stevenson et al., *op. cit.*).

From 1998–2006, we monitored four *D. couperi* populations at Fort Stewart Military Installation in the lower Coastal Plain of southeastern Georgia. For the purposes of this note, we define a *D. couperi* population as overwintering adult *D. couperi* occupying a discrete sandhill area known to support *G. polyphemus* that is separated > 6.0 km from a similar sandhill area. Distances between populations in this study ranged from 6.5–27 km. We monitored these populations by surveying for snakes from mid-November through mid-March (see Stevenson et al., *op. cit.* for additional details). During the seven-year period we captured and marked 77 individual *D. couperi* (51 males, 26 females). We recaptured 33 of these snakes (20 males, 13 females) in at least one additional survey year, and we recaptured 17 individuals (12 males, 5 females)

in 3–5 different survey years. Of these multi-year captures, we documented only a single instance of a snake moving between populations.

On 8 November 2002, we captured an adult male *D. couperi* (SVL = 140 cm; 1.86 kg) in sandhill habitat along Beards Creek, Long Co., Georgia, USA. The snake was marked with a passive integrated transponder (PIT) implanted subcutaneously and was released at the site of capture. On 23 December 2004, the snake was recaptured 22.2 km linear distance NE of its initial capture site in sandhill habitat N of the Canoochee River, Bryan Co., Georgia, USA. The snake was twice recaptured (at different tortoise burrows) the following fall/winter at the same sandhill site in Bryan Co.

The snake may have moved in search of mating opportunities; the Long County site where it was originally captured seems to support a very small *D. couperi* population, with only four males and no females found during our eight-year survey, while the site it moved to supports a larger population (9 adult females captured). If this snake moved between sites in a direct route (ca. 22 km), it would have traversed extensive areas of mesic pine flatwoods dotted with depressional wetlands and would have crossed numerous blackwater creek swamps. Because of poorly-drained soils, *G. polyphemus* are very uncommon and locally distributed on this part of Fort Stewart. Alternatively, a less direct route (ca. 27 km) would have the snake traveling north along a north-south trending upland terrace, and then traveling east (parallel to the Canoochee River), often through sandy uplands populated by *G. polyphemus*.

Interpopulation dispersal in snakes is generally thought to be low (Parker and Plummer 1987. *In* Seigel et al. [eds.], Snakes: Ecology and Evolutionary Biology, pp. 253–301. McGraw Hill, New York, New York), and even short distances (e.g., 1.6 km) of unsuitable habitat can potentially restrict gene flow (Prior et al. 1997. Conserv. Biol. 11:1147–1158). This type of long-distance movement by an imperiled species underscores the importance of conserving large tracts of land and the value of maintaining habitat connectivity and dispersal corridors between populations.

We thank David C. Rostal for first capturing the snake, and M. Rebecca Bolt, Kevin M. Enge, and John G. Palis for helpful comments on the manuscript.

Submitted by **DIRK J. STEVENSON**, Project Orianne, Indigo Snake Initiative, 414 Club Drive, Hinesville, Georgia 31313, USA (e-mail: dstevenson@projectorianne.org); and **NATALIE L. HYSLOP**, Wildlife Ecology and Conservation, University of Florida, Gainesville, Florida 32611, USA (e-mail: hyslopn@warnell.uga.edu).

DRYMARCHON COUPERI (Eastern Indigo Snake). **DEATH FEIGNING.** At 1100 h on 5 November 2008, I captured an adult female *Drymarchon couperi* (SVL = 1080 mm) ca. 10 km SW of Townsend, McIntosh Co., Georgia, USA. When found, the snake was on the ground, moving through open-canopied sandhill habitat, vegetated with scattered clumps of Saw Palmetto (*Serenoa repens*); numerous Gopher Tortoise (*Gopherus polyphemus*) burrows were located within 100 m of the capture site. Upon capture, the snake actively struggled in my hands, rattled its tail, flattened its neck vertically, and released musk—characteristic defensive behaviors for wild *D. couperi* when threatened (Stevenson et al. 2008. *In* Jensen et al. [eds.], Amphibians and Reptiles of Georgia, pp. 339-341. University of Georgia Press, Athens). Ambient temperature at the time of capture was 18°C, following an overnight low of 12°C; skies were cloudy and a very light, misty rain was falling. The snake had recently shed its skin, and appeared in good health.

When I attempted to pose the snake for photographs, it became motionless, rolled its head and neck to one side, and gaped (Fig. 1). It lay on the ground stationary and immobile, its mouth continuously open in the same position, for ca. 5 minutes. Occasionally, its tail would slowly and weakly twitch back and forth. Similar to Gehlbach's (1970. Herpetologica 26:24–34) description of death-feigning in the Western Coachwhip (*Masticophis flagellum testaceous*), the head and neck of the *D. couperi* were rigid while the posterior part of the snake was limp, and a bend in the neck caused the snake's head to face downward. When I moved to a distance of 5 m, within 45 seconds the *D. couperi* closed its mouth, fully righted itself, and crawled off normally. Twice, I captured the snake and elicited the behavior described above—both times followed by the snake again closing its mouth, righting itself, and crawling away within ca. 45 seconds when I retreated. It never struck or made any attempt to bite during the entire time it was being handled.

On 3 December 2008, I observed a second adult female *D. couperi* (SVL = 1295 mm; Wheeler Co., Georgia, USA) exhibit the same behavior. This snake, eyes opaque and nearing a shed event, was captured as it emerged from a tortoise burrow at 1210 h on a clear, sunny day (temperature at time of collection = 10°C) following a cold night (2.2°C) and frost event. The snake displayed the behavior for ca. 1 minute during my processing and marking; it moved slowly, albeit normally, when released at its capture burrow.

I interpret this behavior as death-feigning (thanatosis), a defensive strategy that has not previously been reported for *D. couperi*. Over a 15-year period (1992–2008), I have captured and handled over 150 *D. couperi* in southern Georgia as part of population moni-

FIG. 1. An adult female Eastern Indigo Snake (*Drymarchon couperi*) exhibiting death-feigning behavior (McIntosh Co., Georgia, USA).

toring studies (Stevenson et al. 2003. Southeast. Nat. 2:393–408), and had never observed this behavior. Similar death-feigning behavior has been observed in Eastern Coachwhips (*M. f. flagellum*) in North Carolina (Palmer and Braswell 1995. Reptiles of North Carolina. Univ. of North Carolina Press, Chapel Hill. 412 pp.) and in the Coastal Plain region of southeastern Georgia, including the Wheeler Co., Georgia site mentioned above (D. Stevenson, unpubl. data).

I thank Jeff Beane for reviewing the manuscript. Eastern Indigo Snake studies in Georgia are supported by Georgia Department of Natural Resources Scientific Collecting Permit 29-WBH-08-206, issued to Christopher L. Jenkins.

FARANCIA ABACURA REINWARDTII (Western Mudsnake). **FEEDING BEHAVIOR.** Rossman (*in* Dundee and Rossman 1989. The Amphibians and Reptiles of Louisiana. Louisiana State Univ. Press, Baton Rouge. 300 pp.) recounts witnessing a captive Western Mudsnake chewing "vigorously back and forth along the trunk" of a Western Lesser Siren (*Siren intermedia nettingi*) "– inflicting deep gashes – before swallowing it headfirst." During mid-morning on 28 June 1995, in a riparian area near the town of Kisatchie, Natchitoches Parish, Louisiana, USA, a repeated faint "yelp" drew my attention to a shallow puddle measuring about 0.3 m^2. Protruding out of the water, near the middle of the puddle, I saw the anterior 15–18 cm of an *F. abacura* that I judged to be about 75 cm total length. The snake had an *S. intermedia* ca. 18–20 cm total length, which was the source of the yelps, grasped by the midsection in its jaws. Most of the snake was completely concealed by the thick layer of dead hardwood leaves covering the bottom of the puddle. As I watched, the *F. abacura* proceeded to chew methodically back and forth along the trunk of the siren before finally swallowing it headfirst. Shortly after swallowing its prey, the snake withdrew the exposed portion of its body straight back into the opening in the submerged leaf litter, completely disappearing from view. This observation confirms that the captive behavior witnessed by Rossman was not unique, and may represent a typical feeding behavior in *Farancia abacura*.

Submitted by **STEPHEN H. SHIVELY**, 350 Castor Plunge Road, Woodworth, Louisiana 71485, USA.

HELICOPS ANGULATUS (Watersnake). **DIET AND REPRODUCTION.** The primarily nocturnal snake *Helicops angulatus* is a large colubrid that occurs in ponds, streams, and rivers of northern South America (Duellman 1978. Univ. Kans. Mus. Nat. Hist. Misc. Publ. 65:1–352; Martins and Oliveira 1998. Herpetol. Nat. Hist. 6:78–150). On 15 September 2007 we collected an adult female *H. angulatus* (SVL = 720 mm) in herbaceous vegetation next to a waterfall in a fragment of Atlantic Forest (12.950°S, 38.375°W; datum WGS84) in the Municipality of Salvador, Bahia State, Brazil. The snake was collected with official authorization (IBAMA-RAN 02010.000230/07-60) and deposited at the Zoologic Museu of Universidade Federal da Bahia (MZUFBA 1921). The specimen was dissected, and food items identified and counted. Except for a small quantity of arthropods (Acarina, Hymenoptera, and Isoptera) that could have been secondarily ingested, stomach contents were composed entirely of four toads—*Rhinella margaritifer* (mean ± SE SVL = 120 ± 4 mm). Anurans and fishes are common prey of *Helicops* spp. (e.g., *H. leopardinus, H. caricaudus*; Marques et al. 2001. Serpentes da Mata Atlântica: Guia Ilustrado para a Serra do Mar. Editora Holos, Ribeirão Preto, São Paulo, 184 pp.; *H. angulatus* in Trinidad—Ford and Ford 2002. Carib. J. Sci. 38:129–132).

The *H. angulatus* was gravid with 17 vitellogenic follicles (mean length = 11.6 mm) and 37 previtellogenic follicles. The reproductive cycle for this species has been reported to last from February to November (Martins and Oliveira, *op. cit*.) with clutch sizes ranging from 11 to 18 (Ford and Ford, *op.cit.*). The observation of anuran predation in a vitellogenic female is further indication of the opportunistic foraging behavior of *H. angulatus*.

We thank the 19o Batalhão de Caçadores, for the permits to work at federal property. The Instituto Brasileiro do Meio Ambiente e Recursos Naturais Renováveis – IBAMA issued permits for the collection of snakes for our study.

Submitted by **JORGE AUGUSTO REIS GUIMARÃES, EDUARDO JOSÉ DOS REIS DIAS** (e-mail: ejrdias@hotmail.com), **LISE CUNHA VILELA**, and **ANDRÉA ROCHA OLIVEIRA**, Faculdades Jorge Amado, Avenida Luis Viana Filho, 6775, Paralela, 41745-130, Salvador, Bahia, Brazil.

HELICOPS POLYLEPIS (Norman's Keelback). **DIET AND INTRASPECIFIC COMPETITION**. The genus *Helicops* is widespread throughout most of South America, from Colombia to Argentina (Rossman 1970. *In* Peters and Orejas-Miranda (eds.), Catalogue of the Neotropical Squamata Part 1. Snakes. U.S. Nat. Mus. Bull. (297):122–125). *Helicops polylepis* is little known and no diet information for the species has been published (Duellman 2005. Cusco Amazónico. Cornell University Press, Ithaca, New York. 433 pp.). Additionally, intra- and interspecific competition has been observed among North American watersnakes and on several occasions a single prey item (i.e., fish or frog) has been attacked by multiple individuals (Himes 2003. J. Herpetol. 37:126–131). Here we identify the first diet item for *H. polylepis* and report an observation of intraspecific competition in this species.

On 28 September 2006 (1056 h) two adult (total length of each ca. 70 cm) *H. polylepis* were observed consuming opposite ends of a freshwater eel, likely *Synbranchus marmoratus* (Fig. 1). A photograph was taken of the event (UTADC 1927), which occurred in a small stream 50 m N of the port at Lake Sandoval (approx. 12.6041667°N, 69.0472222°W, datum: WGS 84; 190 m elev.). Lake Sandoval is located in the Provincia Tambopata, ca. 3 km E of the Rio Madre de Dios in southeastern Peru. Both the snakes and their prey were identified from the photo and *H. polylepis* was distinguished from other *Helicops* by having paravertebral spots less than 3 scales long (Rossman, *op. cit.*). Duellman (2005, *op. cit.*) conjectured that this species likely feeds on fish and/or tadpoles and *Synbrachus marmoratus* has been found to be eaten by *H. infrataeniatus* and *H. leopardinus* (Aguiar and Di-Bernardo 2004. Stud. Neotrop. Fauna Environ. 39:7–14; Ávila et al. 2006. J. Herpetol. 40:274–79).

LAMPROPELTIS GETULA GETULA (Eastern Kingsnake). **SCAVENGING AND DIET**. *Lampropeltis getula* is an ophiophagous colubrid known to consume other colubrid, viperid and elapid snakes (Ernst and Ernst 2002. Snakes of the United States and Canada. Smithsonian Institution Press, Washington D.C. 661 pp.). Here we report evidence that *L. getula* may venture out onto roads to scavenge dead snakes that have been killed by vehicles, in turn exposing themselves to road mortality. Additionally, we report a novel diet record for *L. getula*, *Pantherophis guttatus* (Red Cornsnake).

Historically, carrion feeding by snakes has been largely downplayed or ignored, despite recent work suggesting that scavenging is a common component of snake behavior (Sazima and Strüssmann 1990. Rev. Brasil. Biol. 50:463–468; Shivik and Clark 1997. J. Exp. Zool. 279:549–553) and the observation that nearly all snake species will readily accept pre-killed prey in captivity (e.g., Rossi 1992. Special Issue: 7th Annual Conference, Assoc. of Rept. and Amph. Vets. 107–108). At least 26 snake species from five families have been observed scavenging carrion from at least 35 species of vertebrate taxa (reviewed in DeVault and Krochmal 2002. Herpetologica 58[4]:429–436). However, because scavenged carcasses are difficult to differentiate from live prey through stomach content or fecal surveys, the majority of scavenging events that take place in the field are likely overlooked. The costs associated with exploiting carrion as a food source are generally low compared to other costs incurred through foraging on live prey (e.g., stalking, production of venom, and potential injury during prey capture). However, the risk of scavenging carcasses from roads is relatively high, especially considering the lengthy amount of time snakes take to consume large food items. Additionally, while the use of carrion as a major food source may be unrealistic for many endothermic scavengers due to its ephemeral and unpredictable availability, snakes' exceptionally low metabolic demands make it possible for them to capitalize on these irregular, energy-rich meals (DeVault and Krochmal, *op. cit.*).

FIG. 1. Road-killed *Lampropeltis getula* (left) with *P. alleghaniensis* protruding from mouth (upper right) and *P. guttatus* protruding from burst body cavity (lower right, partially obscured by *P. alleghaniensis*).

At 1130 h on 2 April 2006, we found a road-killed female *L. getula* (SVL = 575 mm SVL; total length = 675 mm) on Turney Anderson Road, 0.15 road mi. E of the junction with Arline Road in Jefferson County, Florida, USA (30.581152°N, 83.844966°W, WGS84; elev. 56.4 m). Protruding from the mouth of the *L. getula* was a dead female *Pantherophis alleghaniensis* (Eastern Ratsnake; SVL = 365 mm; total length = 455 mm), ca. 70 mm of which had been ingested by the *L. getula*. Additionally, protruding from the stomach through the body wall of the *L. getula* was a partially digested segment of a *Pantherophis guttatus* (Red Cornsnake) of indeterminable sex, measuring at least 240 mm SVL (Fig. 1). Surprisingly, *P. guttatus* has not been documented in the literature as a food item for *L. getula*, although at least nine other colubrid species including conspecifics and *P. alleghaniensis* have been recorded (Ernst and Ernst, *op. cit.*).

Our findings suggest potential direct costs (mortality) for snakes scavenging roadkill or foraging on roads and reports a new aspect of the feeding ecology of *L. getula*.

LIOPHIS ALMADENSIS (NCN). **PREDATION.** *Liophis almadensis* is a small terrestrial xenodontine snake that occurs from the southern side of the Rio Amazonas (Marajó Island) to the Rio

Grande do Sul in Brazil, south of the Paraguayan Chaco (Dixon 1991. Texas J. Sci. 43:225–236). This species feeds on anurans and possesses red ventral coloration contrasting with a predominantly gray dorsum (Marques et al. 2005. Serpentes do Pantanal. Holos Editora, Ribeirão Preto, SP. 179 pp.). There are no published records of predation on *L. almadensis*. At 1700 h on 29 July 2008, I observed a *Furnarius rufus*, a large ovenbird (Rufous Hornero, Furnariidae), handling a *L. almadensis* along an unpaved road that crosses a pasture (30.2042°S, 50.8700°W; datum Córrego Alegre; elev. 50 m) in a rural area in municipality of Viamão, State of Rio Grande do Sul, south Brazil. On my approach, the bird flew off, leaving the snake (juvenile male; SVL = 190 mm; total length = 204 mm) on the ground. Examination of the snake revealed that the top of its head, between the eyes, was deeply perforated by bird's beak. Five more perforations and additional peck marks were present on the snake's dorsum and part of the digestive tract was exposed. The snake was still showing motor reflexes, indicating that it had been recently attacked.

This observation reports a novel predator for *L. almadensis*. The record is even more interesting because *F. rufus* is known to eat only invertebrates (arthropods and earthworms) and seeds (Sick 1988. Ornitologia Brasileira: uma Introdução. Universidade de Brasília, Brasília, DF. 828 pp.) and the red ventral coloration of *L. almadensis* may mimic a sympatric coral snake (*Micrurus altirostris*). The *L. almadensis* voucher (MCP 18412) was deposited in the Coleção Herpetológica do Museu de Ciência e Tecnologia da PUCRS.

I thank Gláucia M. F. Pontes for snake identification, Marcio Borges Martins and Carlos Roberto R. Oliveira for suggestions on the manuscript.

Submitted by **ALEXANDRO M. TOZETTI**, Laboratório de Ecologia de Vertebrados Terrestres. Instituto de Ciencias Biológicas, Universidade Federal do Rio Grande. Av. Itália, km 8, Rio Grande, RS, Brazil; e-mail: alexandrotozetti@furg.br.

NERODIA ERYTHROGASTER (Plain-bellied Watersnake). **FORAGING BEHAVIOR**. Published observations of watersnake foraging behavior in nature are few (Gibbons and Dorcas 2004. North American Watersnakes: A Natural History. Univ. Oklahoma Press, Norman. 438 pp.). On 3 June 2006, I observed a *Nerodia erythrogaster* (total length = 76 cm) in a shallow (< 3 cm), 1.5 m × 3 m, muddy-water pool in a floodplain forest, Union County, Illinois, USA. As I entered the pool, the snake began to make a series of circular loops, first in one direction, then in the other. Initially, I assumed the snake was making an ineffectual attempt to escape. As I watched, however, I realized it was foraging for prey.

The snake foraged as follows: with head and body just under the water's surface, the snake rapidly coiled in one direction one or more times, ducked its head beneath its coiled body, repeated the coiling motion in the opposite direction, ducked its head beneath its coiled body, repeated the coiling motion in the opposite direction, etc. (Fig. 1). Forward movement, including change of direction, was continuous. The overall pattern created by the snake was that of a series of figure eights. However, because the loops did not follow the same path each time, the snake foraged over a different area with each change in direction. Foraging behavior was confirmed when, after performing a series of figure eights, the snake raised its head above water holding a small fish in its mouth. Four species of fishes (*Ameiurus natalis*, *Aphredoderus sayanus*, *Esox americanus*, and *Notemigonus crysoleucus*; all ≤ 75 mm total length) and *Rana clamitans* tadpoles (≤ 25 mm total length) inhabited in the pool.

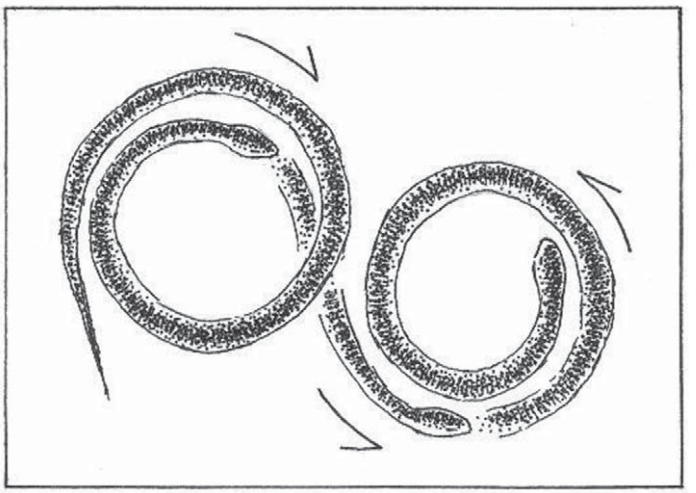

FIG. 1. Movement path of foraging *Nerodia erythrogaster*.

Evans (1942. Chicago Nat. 5:53–55) described watersnakes (*Nerodia* spp.) moving, open-mouthed, "through the water…in a series of figure eights, the entire body following the path of the head." Although Evans assumed the snakes were foraging, he never saw snakes actually capture prey while engaging in the behavior. Although I could not see if the snake foraged open-mouthed due to the turbidity of the water, it is likely that the foraging behavior I observed is that described by Evans. My observation of prey capture supports Evans' contention that he observed watersnakes foraging.

I thank J. W. Gibbons for providing a copy of the Evans reference, and E. L. Palmer for rendering the figure.

Submitted by **JOHN G. PALIS**, P.O. Box 387, Jonesboro, Illinois 62952, USA; e-mail: jpalis@yahoo.com.

OPHEODRYS AESTIVUS (Rough Greensnake). **FORAGING**. *Opheodrys aestivus* is an entomophagous colubrid known to consume spiders, harvestmen, millipedes, isopods, land snails, small hylid frogs and insects from several orders (Coleoptera, Ephemeroptera, Lepidoptera, Odonata, Orthoptera; Ernst and Ernst 2002. Snakes of the United States and Canada. Smithsonian Institution Press, Washington D.C. 661 pp.). Captive feeding trials on orthopterans have suggested that vision is the sole sense used to detect moving prey; motionless insects were overlooked despite tongue flicking (Goldsmith 1986. Southwest. Nat. 31:246–249). Here, we report evidence that *O. aestivus* will forage on visually concealed, gall-living insects (Price et al. 1987. Environ. Entomol. 16:15–24).

At 1445 h on 26 July 2007, one of us (KPD) spotted an adult *O. aestivus* in a Water Tupelo (*Nyssa aquatica*) along a boardwalk trail at the Virginia Marine Science Center, Virginia Beach, Virginia, USA (36.816144°N, 75.987989°W, WGS84; elev. <1 m). The trail is adjacent to the southern shore of Lake Rudee, a brackish water estuary that empties into the Atlantic Ocean via Rudee Inlet. The

FIG. 1. *Opheodrys aestivus* probing the surface of a crown gall in search of concealed insects.

snake was probing the surface of a large (>30 cm diameter) decayed woody "crown gall" identified as being caused by a bacterium, *Agrobacterium tumefaciens* (Smith and Townsend 1907. Science 25:671–673; Stafford 2000. Bot. Rev. 66:99–118). After several minutes, the snake inserted the anterior third of its body through a concealed hole in the gall and withdrew a minute later with a live insect, which it immediately swallowed. We watched and photographed the snake for 15 minutes as it repeated this behavior (Fig. 1) before it departed.

We thank S. Covert (University of Georgia) and S. Fraedrich (U.S. Forest Service) for their assistance in identifying the gall.

OVOPHIS MONTICOLA MAKAZAYAZAYA (Taiwan Mountain Pitviper). **DIET**. *Ovophis monticola* feeds primarily on small rodents and insectivorous mammals (Zhao et al. 1998. Fauna Sinica-Reptilia Vol. 3. Science Press, Beijing. 522 pp.). However, little natural history or dietary information has been published regarding *O. monticola makazayazaya*, a subspecies inhabiting Taiwan. This is likely a consequence of nocturnal and secretive behavior, activity during periods of light rain or fog, and occurrence in montane forests (Mao, pers. obs.).

On 24 November 2007, a female *O. m. makazayazaya* (SVL = 498 mm; tail length = 72 mm) was found in a funnel trap along a drift fence in Minchi, Yilan County, Taiwan (24.6442°N, 121.4631°E; datum WGS84; elev. 1130 m). The snake had an obvious bulge at mid-body, which slightly reduced its mobility. We palpated a partially digested *Niviventer coxingi* (Spinous Country Rat; 15.4 g), which had been ingested head-first. Based on a comparison with specimens in the National Museum of Natural Science (NMNS), Taiwan, we believe the rat had a body length ca. 95–130 mm. The snake was released.

Niviventer coxingi is endemic to Taiwan and occurs throughout the country in mountainous forests below 2200 m elevation (Pei 1995. Zool. Stud. 34:55–58) and appears to decrease activity in response to strong moonlight (Lin et al. 1995. Notes and Newsletter of Wildlifers 3:11–13). Although the moon was nearly full at the time of these observations, dense fog may have reduced the lunar effect on the rat's activity pattern.

We thank Y.-J. Chen (NMNS) for assistance.

Submitted by **JEAN-JAY MAO** (e-mail: jjmao@niu.edu.tw), **CHIN-LIANG HSU, WEI-HAN CHEN**, and **TIEN-SHIU HSIEH**, Department of Forestry and Natural Resources, National Ilan University. PHILODRYAS NATTERERI (Paraguay Green Racer). **DIET.** The diet of the medium-sized colubrid snake *Philodryas nattereri* is relatively well studied and includes lizards and mammals (Vitt 1980. Pap. Avul. Zool. 34:87–98.). On 24 November 2008, at 1400 h, we found an adult female *P. nattereri* (SVL = 879 mm; 175 g after dissection) that had been killed by local farmers, in a fish farm near Pentecoste, Ceará, Brazil (3.82145°S, 39.33824°W; datum WGS 84). Upon dissection, we found a *Myotis nigricans* (Little Brown Bat), a small bat of the family Vespertilionidae, that had been eaten head first by the snake. The prey was nearly intact and weighed 7 g. This insectivorous bat species is widespread in Central and South America and inhabits open habitats, including urban areas (Emmons and Feer 1999. Neotropical Rainforest Mammals, a Field Guide. Univ. Chicago Press, Chicago, Illinois. 307 pp.). The ingestion of bats by snakes is seldom reported in the literature, but may not be infrequent because bat colonies can represent a potential concentration of food that is constantly available (Esberárd and Vrcibradic 2007. Rev. Bras. Zool. 24:848–853). There is a report of bat predation by *Philodryas viridissimus*, which is primarily arboreal (Otto and Miller 2004. Herpetol. Rev. 35:277). To our knowledge, this is the first record of bat predation by the mainly terrestrial *P. nattereri*. The snake and the bat are deposited together in the herpetological collection of Universidade Federal do Ceará (CHUFC 3087).

We thank the Fundação Cearense de Amparo a Pesquisa (FUNCAP) for financial support, the Instituto Brasileiro do Meio Ambiente e Recursos Naturais (IBAMA) for the license (License number: 18596-1) to collect snake samples in the studied area.

Biologia, Bl. 905, CEP 60.455-760, Fortaleza, CE – Brazil.

PSOMOPHIS JOBERTI (Sand Snake). **DEFENSIVE BEHAVIOR**. The genus *Psomophis* is composed of small, poorly-understood colubrid snakes with short tails that terminate in a spine (Myers and Cadle 1994. Am. Mus. Novitates 3101:1–33).

Psomophis spp. are restricted to South America and *P. joberti* is the only species that occurs in northeastern Brazil, which is dominated by caatinga vegetation (França et al. 2006. Occas. Pap. Oklahoma Mus. Nat. Hist. 17:1–13). On 3 July 2008, we collected a *P. joberti* (Co-0826) in São Gonçalo do Amarante Municipality (3.5741667°S, 38.8886111°W; datum WGS84), state of Ceará, Brazil, that displayed a defensive behavior after being collected—bending its body and pressing the tail spine against the collector's hands, causing slight pain, but not inflicting any damage to the skin. The same behavior was observed in another specimen (Co-0829) collected on 12 September 2008 from Itapipoca Municipality, Brazil (3.4175°S, 39.6919444°W; datum WGS84). *Psomophis* are said to not bite defensively when touched (Carvalho and Nogueira 1998. Cad. Saúde Pública. 14:753–763). Lima-Verde (1991. Unpublished thesis, Universidade Federal do Ceará, Fortaleza, Brazil) collected 57 specimens of *P. joberti* in northeastern Brazil and described the species as diurnal, oviparous, and gentle. Although the defensive behavior reported here has not been noted previously, all works mention the presence of the tail spine. Tail spines and spine-pressing behavior have been reported in snakes of the genera *Typhlops* (Richmond 1955. Am. Mus. Novitates 1734:1–7), *Farancia* (Ernst and Ernst 2003. Snakes of the United States and Canada. Smithsonian Inst. Press, Washington DC. 668 pp.), and *Carphophis* (Ernst and Ernst, *op. cit.*).

PYTHON MOLURUS BIVITTATUS (Burmese Python). **CLUTCH SIZE.** Through instances of pet release or escape, a reproducing population of *Python molurus bivittatus*, native to Southeast Asia, has recently become established in and around Everglades National Park, Florida, USA (Snow et al. 2007. *In* Henderson and Powell [eds.], Biology of the Boas and Pythons, pp. 416–438. Eagle Mountain Publishing, Utah). On 2 March 2007, an adult female *P. m. bivittatus* (EVER 055842; SVL = 4240 mm; total length = 4710 mm; 56.69 kg) was captured near Ficus Pond (25.3749ºW, 80.8274ºW; datum WGS 1984) in Everglades National Park, Florida, USA. This specimen contained 85 large vitellogenic follicles (44.4 to 53.5 mm diameter) and 7.18 kg of fat bodies. Of these follicles, 48 were located in the right ovary (weight 2.49 kg) and 37 in the left ovary (weight 1.90 kg). A previous study reports a mean clutch size for *P. m. bivittatus* in Florida of 35.75 ± 3.35 (N = 8; range 19–46; Brien et al. 2007. Herpetol. Rev. 38:342). This finding of 85 follicles marks the largest recorded clutch size for *P. m. bivittatus* found in Florida.

PYTHON MOLURUS BIVITTATUS (Burmese Python). **DIET.** Although Burmese pythons are native to southeastern Asia, both juvenile and adult specimens have been collected in Everglades National Park and surrounding areas in Florida since the mid 1990s (Snow et al. 2007. *In* Henderson and Powell [eds.], Biology of the Boas and Pythons, pp. 416–438. Eagle Mountain Publishing, Utah). On 20 March 2006, an adult female *P. m. bivittatus* (SVL = 4320 mm; total length = 4870 mm; 69 kg) was captured near Ficus Pond (25.3739°N, 80.8241°W, datum: WGS 1984; elev. <1 m) in Everglades National Park, Florida, USA. This specimen was deposited in the Florida Museum of Natural History, University of Florida (UF 146019). While examining gut contents, we found hair and four hooves of a fawn White-tailed Deer *(Odocoileus virginianus). Python m. bivittatus* is a dietary generalist known to eat a wide variety of mammalian, avian, and crocodilian prey (Snow et al., *op. cit.*). This observation constitutes the first record of White-tailed Deer predation by *P. m. bivittatus*.

RHINOBOTHRYUM LENTIGINOSUM (Ringed Tree Snake). **DIET AND MAXIMUM SIZE**. The *Rhinobothryum* are poorly known (Greene 1997. Snakes: the Evolution of Mystery in Nature. Univ California Press, Berkeley. 351 pp.). *Rhinobothryum lentiginosum* is a nocturnal lizard specialist that seems to prefer riparian forest or edges of creeks or streams, as has been noted for *R. bovalli* (Solórzano 2004. Snakes of Costa Rica: Distribution, Taxonomy, and Natural History. Inbio, San José, Costa Rica 791 pp.). Here I report a *R. lentiginosum* that had consumed a juvenile green iguana (*Iguana iguana*) at Vitória do Xingu, Pará State, Brazil. At 2100 h on 11 July 2007, a large *R. lentiginosum* was found moving close to a fishing camp on the banks of the Xingu River and was killed. A visitor of the camp, Ian-Arthur Sulocki (IAS), took several photographs of the snake and the juvenile green iguana contained in the snake's gut (Fig. 1). Based on the description and photographs by IAS, the snake was at least 1800 mm total length, substantially

FIG.1. *Rhinobothryum lentiginosum* (decapitated) with juvenile *Iguana iguana* that it had consumed.

larger than the largest (total length = 1498 mm) reported by Cunha and Nascimento (*op. cit.*). Thus, this event is noteworthy not only because it reports a new prey species and additional case of saurophagy in *R. lentiginosum*, but also because the snake likely represents the maximum size for this species. Additionally, this note documents a novel predator for juvenile *Iguana iguana* (Greene et al. 1978. J. Herpetol. 12:169–176).

I thank Ian-Arthur Sulocki for reporting the event and contributing photographs.

Submitted by **MARCELO RIBEIRO DUARTE**, Laboratório de Herpetologia, Instituto Butantan, Av. Vital Brazil, 1500, São Paulo, SP, Brazil, CEP 05503-900; e-mail: mrduarte@butantan.gov.br.

SIBON ANNULATUS (Ringed Snaileater). **MAXIMUM SIZE.** *Sibon annulatus* is a small snake for its genus and has previously been recorded to a maximum total length of 557 mm (Savage 2002. Amphibians and Reptiles of Costa Rica: A Herpetofauna Between Two Continents, Between Two Seas. Univ. Chicago Press, Chicago, Illinois. 934 pp.). At 2230 h on the 31 December 2004, during a nocturnal visual encounter transect for amphibians, we found an adult female *S. annulatus* in *Manicaria* swamp forest at Caño Palma Biological Station (8 km N of Tortuguero, Limón Province, Costa Rica). The snake was found at a perch height of 4.5 m in a *Loreya* sp. (Melastomataceae) tree. The live snake measured 362 mm SVL, 214 mm tail length, and weighed 8.8 g. At 576 mm total length, this specimen is the longest known *S. annulatus.* The specimen was collected under permit (Resolucion No. 171-2004-OFAU) and deposited in the herpetological collections at Universidad de Costa Rica.

We thank the Canadian Organization for Tropical Education and Rainforest Conservation (COTERC) for permission to study at Caño Palma Biological Station, Xavier Guevara at the Ministerio de Recursos Naturales Energia y Minas (MINAE) for permits, Federico Bolaños of Universidad de Costa Rica for access to collections, and Farnborough College of Science and Technology for assistance with literature.

SISTRURUS CATENATUS EDWARDSII (Desert Massasauga). **DIET, PREY SIZE, AND FEEDING-RELATED MORTALITY.** *Sistrurus catenatus edwardsii* feeds on lizards, small mammals, small snakes, centipedes, and anurans (Holycross and Mackessy 2002. J. Herpetol. 36:454–464). Whiptails of the genus *Aspidoscelis* have been reported to be in the diet of *S. c. edwardsii*, however *A. marmorata* (Marbled Whiptail) has not yet been identified as prey (Holycross and Mackessy, *op. cit.*). This is rather intriguing, given the overlap that exists for both species' known geographic ranges (Degenhardt et al. 1996. Amphibians and Reptiles of New Mexico. Univ. New Mexico Press, Albuquerque. 431 pp.). Furthermore, little published information exists regarding prey size for *S. c. edwardsii*. Here, I report feeding-related mortality of an *S. c. edwardsii* following consumption of an adult *A. marmorata*.

At 1018 h on 7 August 2008, I discovered a deceased female *S. c. edwardsii* (TCWC 93556) lying in the bottom of a large sand dune blowout in Lea County, New Mexico, USA (32.7847°N, 103.8089°W; datum WGS 84; elev. 1173 m). The individual was lying dorsum up, appeared bloated, and had recently deceased. Both lizard and snake tracks were observed near the dead snake. The individual was collected and dissected to determine what was causing the large bulge in the snake's mid-section. Upon dissection, I discovered that the snake had consumed a female *A. marmorata* (TCWC 93557). The lizard's girth had caused a 35 mm long rupture in the snake's stomach which was likely the ultimate cause of death for the snake.

The *S. c. edwardsii* measured 310 mm SVL and 18 g mass post mortem and the *A. marmorata* measured 100 mm SVL and 21 g mass post mortem. This indicates that the snake attempted to ingest a prey item 1.17 times its own mass. This measurement is slight in comparison to the record for snakes (relative prey mass = 1.72; Mulcahy et al. 2003. Herpetol. Rev. 34:64); however, perhaps it illustrates a differential consumption/mortality threshold exists among species or individuals.

This observation is noteworthy for two reasons. First, although *S. c. edwardsii* and *A. marmorata* overlap in geographic range, their trophic relationship had not yet been clarified. Second, it indicates the consumption of large prey items may result in increased energy stores for *S. c. edwardsii*, but the potential threat of death due to a ruptured stomach exists.

Submitted by **DANIEL J. LEAVITT**, Texas Cooperative Wildlife Collection, Department of Wildlife and Fisheries Science, Texas A&M University, College Station, Texas 77843-2258, USA; e-mail: dlea886@neo.tamu.edu.

TANTILLA GRACILIS (Flat-headed Snake). **ARACHNID PREDATION**. *Tantilla gracilis* is found in the south-central region of the United States and is known to have 20 species of mammalian, avian, and snake predators (Ernst and Ernst 2003. Snakes of the United States and Canada. Smithsonian Institution Press, Washington, D.C. 668 pp.). Because of the highly fossorial nature of this species, much of its life history remains unknown (Cobb 2004. Copeia 2004:397–402) and spider predators have not been reported. Here we report the first arachnid predation documented for *T. gracilis*.

On 27 September 2007, at ca.1000 h, a juvenile (SVL = 74 mm; tail length = 22 mm; 0.095 g) *T. gracilis* (UTA R-55476) was observed in the web of a spider (0.034 g) of the genus *Steatoda* (Theriidae); the snake was being consumed from behind the neck by its captor. At its lowest point, the juvenile *T. gracilis* was ca. 23 cm from the floor. It is highly unlikely that the snake fell or climbed into the web and therefore it is probable that the spider hoisted the snake to this position. While in the web, the snake's tail was tethered to its neck with webbing. Photographs were taken of the event, which occurred in the shower room of a large outdoor restroom at Camp Tyler, Smith County, northeastern Texas, USA (32.2566722°N, 95.1847778°W; datum WGS 84; elev. 129 m). This restroom hosts a group of >50 adult spiders of the family Theridiidae.

We thank J. A. Campbell and C. J. Franklin for cataloguing the photograph and specimen, D. Formanowicz for identifying the spider to genus, and V. A. Cobb for reviewing this manuscript. We also thank Alan and Jenny Byboth, Jim Connally, and the Camp Tyler Foundation for giving us a welcome place to live at Camp Tyler during much of our stay at Tyler. The specimen was collected under Texas Parks and Wildlife scientific permit no. SPR-0691-418.

JADIN**, Amphibian and Reptile Diversity Research Center and Department of Biology, University of Texas at Arlington, Arlington, Texas 76019, USA.

TANTILLA OOLITICA (Rim Rock Crowned Snake). **DEFENSIVE BEHAVIOR.** At 0950 h on 25 May 2007 we captured a *Tantilla oolitica* (total length = 199 mm; 1.65 g) resting in an elongate coil under a rotting board in Dove Creek Hammock, Key Largo, Florida, USA, during a study by The Institute of Regional Conservation to determine the conservation status of this species. The ambient temperature was 25.2°C and the relative humidity was 80%. Upon capture, the snake began to feign death by remaining limp in our hands with its mouth open and tongue slightly extended. It continued to behave this way for about 10 minutes as we measured and weighed the snake. The act was very convincing and the three of us present at the time believed it to be dead or dying. We were particularly convinced of this when it continued the act even when placed upon a rock. It remained as posed for several minutes before slowly starting to crawl away. When we started to handle the snake again, it repeated the process of feigning its death. This cycle continued for 30 minutes until the snake was deemed healthy and was released. The ecology of this species is poorly-understood and whether this behavior represents a common defensive response or an isolated instance remains unknown.

MAZZOTTI**, University of Florida, Fort Lauderdale Research and Education Center, 3205 College Avenue, Fort Lauderdale, Florida, 33314-7719, USA (e-mail: fjma@ufl.edu).

THAMNOPHIS SIRTALIS (Common Gartersnake). **SCAVENGING.** Although snakes often accept dead food items in captivity, observations of scavenging by wild snakes are relatively rare. In a recent review, DeVault and Krochmal (2002. Herpetologica 58:429–436) suggested that scavenging may be a deliberate feeding strategy in some snake species rather than just an opportunistic event.

Thamnophis sirtalis is considered to be a dietary generalist and studies have indicated that it preys upon invertebrates, fishes, amphibians, mammals, and birds (Rossman et al. 1996. The Garter Snakes, Evolution and Ecology. Animal Nat. Hist. Series, vol. 2. Univ. of Oklahoma Press, Norman. 332 pp.). Published records of scavenging by wild *T. sirtalis*, however, are rare, and to date only six reports exist, all involving birds and anurans as prey. Gray (2002. Herpetol. Rev. 33:142–143) suggested that scavenging of dead anurans by *T. sirtalis* may be common but scavenging of birds is rare. However, there are four reports of this species scavenging birds (Ruthven 1908. Bull. U.S. Natl. Mus. 61:1–201; Feldman and Wilkerson 2000. Herpetol. Rev. 31:248; Gray, *op. cit.*; Sajdak and Sajdak 2007. Herpetol. Rev. 30:229–230) and only two on frogs (Ruthven, *op. cit.*; Brown 1979. Brimleyana 1:113–124). The latter two reports lack detail and only Ruthven (*op. cit.*) specified the scavenged anuran species (*Rana clamitans*; Green Frog). Given the abundance of *T. sirtalis* in many areas and high levels of road mortality often suffered by frogs and other prey items, frequent opportunities for scavenging should occur. Thus, the scarcity of reports suggests that scavenging by *T. sirtalis* is either rare in nature or frequently goes unreported. Here, I report two additional instances of scavenging of anurans by *T. sirtalis*.

At 1815 h on August 8 2008, I observed a *T. sirtalis* (total length ca. 30 cm) consuming a small (SVL ca. 3.0 cm), recently road-killed *Anaxyrus terrestris* (Southern Toad) on Road 161 (gravel) in Francis Marion National Forest, Berkeley County, South Carolina, USA (33.1853°N, 79.6946°W; datum WGS84). The incident occurred on the road surface approximately one meter from the heavily vegetated road shoulder. When discovered, the snake had already ingested the anterior one-third of the toad and continued to ingest it in my presence; complete ingestion took an additional six minutes.

At 1515 h on 17 September 2008, I observed another adult *T. sirtalis* (total length ca. 60 cm) attempting to engulf a road-killed *Lithobates pipiens* (Northern Leopard Frog; SVL ca. 7.5 cm) on Lyman Rd. (blacktop) bordering the southern edge of Big Bend State Fish and Wildlife Area, Whiteside County, Illinois, USA (41.6332°N, 90.0417°W; datum WGS84). The incident occurred

on the blacktop about 50 cm from the road shoulder, which was heavily vegetated. In this case, the frog was not freshly killed and desiccation of the skin indicated that it was killed about an hour before the observation. The anterior portion of the frog was stuck to the road surface and the snake was rather awkwardly attempting to ingest the left rear leg. The snake released it upon my approach. Following this observation, three more adult *T. sirtalis* and four more road-killed adult *L. pipiens* were observed on the road near the shoulder within 20 m of the location where the scavenging incident occurred. Despite observing the road for about 30 minutes, no other incidents of scavenging were noted.

Submitted by **ALLAN L. MARKEZICH**, Department of Natural Sciences and Engineering, Black Hawk College, Moline, Illinois 61265, USA; e-mail: markezicha@bhc.edu.

TOXICOCALAMUS STANLEYANUS (Stanley's Forest Snake). **DIET.** Snakes of the genus *Toxicocalamus* are widespread in New Guinea, with published reports suggesting that the species *T. stanleyanus* is relatively common in the Purari basin region of Papua New Guinea (PNG; O'Shea 1996. A Guide to the Snakes of Papua New Guinea. Independent Publishing, Port Moresby, PNG. xii + 239 pp.). There is some evidence that *Toxicocalamus* spp. prey on earthworms (O'Shea, *op. cit*.). However, because of the secretive nature of these snakes, little is known of the ecology of many of the species and no data are available on the size of earthworms typically consumed for any species. While conducting herpetological censuses on 1 December 2008, at 1216 h (Australian EST), I captured a *T. stanleyanus* (total length ca. 670 mm) active in a disturbed area of lowland rainforest in the Purari basin of PNG (7.4955556°S, 145.3594444°E; datum WGS84; elev. 110 m). Immediately following capture, the snake was placed in a bag in a cooler maintained at 24°C. On checking the snake five hours later, it was revealed that the specimen had regurgitated a large, partly digested earthworm (Class Oligochaeta) measuring 150 mm in total length and 17 mm in width at mid-body. Following proper identification, the snake was released

Submitted by **BRETT A. GOODMAN**, School of Marine & Tropical Biology, James Cook University, Townsville, Queensland, 4811, Australia. Current address: Ecology and Evolutionary Biology, University of Colorado, Ramaley N122, Campus Box 334, Boulder, Colorado 80309, USA; e-mail: Brett.Goodman@colorado.edu.

TYPHLOPS ANOUSIUS (NCN). **MAXIMUM SIZE.** On 8 March 1978, N. Drosdov collected a male *Typhlops anousius* (CZACC 4.5530; Colecciones Zoológicas del Instituto de Ecología y Sistemática, Cuba) from Tortuguilla, San Antonio del Sur municipality, Guantánamo province, Cuba. The specimen measured 273 mm SVL and 5 mm tail length. It had 24 scale rows anteriorly, reducing to 22 posteriorly at 7.6% TL or 49th middorsal scales row, 460 middorsal scale counts, 13 dorsal and 14 ventral caudal counts, snout sharp-pointed, rostral broad in dorsal aspect, 0.82 widest part of the posterior rostral to the internasal sutures in dorsal view / standard length of the rostral from the internasal sutures to the posterior tip in dorsal aspect (RWD/RLD). The body was straight-sided and very acuminate posteriorly, and lacked pigmentation. The specimen was previously identified as *T. biminiensis* (by the collector and also by Orlando H. Garrido). I have re-identified the specimen as *T. anousius*. The specimen is a topotype and the first specimen of *T. anousius* reported since the species was described by Thomas and Hedges (2007. Zootaxa 1400:1–26). The previously-reported maximum length for this species is 193 mm SVL. Thus, this record represents a substantial increase in maximum size for the species and extends the range of variation in middorsal scale counts from 465–513 to 460–513 and RWD/RLD from 0.74–0.77 to 0.74–0.82 (Thomas and Hedges, *op. cit.*).

Submitted by **MICHEL DOMÍNGUEZ,** Ave. de Niza 3, 6ºA, Alicante, 03540, Spain; e-mail: micheldd@hotmail.es.

TYPHLOPS BRONGERSMIANUS (Brongersma's Threadsnake). **REPRODUCTION.** The genus *Typhlops* contains 121 species of pantropical snakes and is the largest of six genera within the Typhlopidae (Kley 2003. *In* M. Hutchins et al. [eds.], Grzimek's Animal Life Encyclopedia, 2nd ed. Vol. 7, Reptiles, pp. 379–385. Gale Group, Farmington Hills, Michigan). Six species of *Typhlops* have been reported for Brazil (Rodrigues and Juncá 2002. Pap. Avul. Zool., São Paulo 42:325–333). The biology of the Typhlopidae is still poorly known and the few available data refer to African species. For Brazil, biological information is scarce and restricted to anecdotal data (Ávila et al. 2006. J. Herpetol. 16:403–405). *Typhlops brongersmianus* is widely distributed through South America (Vanzolini 1972. Zool. Mededel. 47:27–29).

A gravid female *T. brongersmianus* (MZUESC 6531; SVL = 350 mm), captured on 21 December 2007 in a pit-fall trap in a cocoa (*Teobroma cacao*) plantation on the campus of Universidade Estadual de Santa Cruz, Ilhéus, southern Bahia, Brazil, was held in captivity until it began ovipositing eggs twelve days later. Fifteen eggs measuring (mean ± SD) 22.5 ± 2.2 mm in length and 13.0 ± 0.3 mm in width were laid. Four of the 15 eggs hatched after 34 days, while the others failed to hatch. The four hatchlings (MZUESC 6532) averaged 91.0 mm SVL and weighed 1.2 g. The hatchlings were light blue in color at birth but changed into the characteristic brown coloration of adults after 12 days. One of the hatchlings shed its skin in a continuous slough and not in pieces as reported by Kley (*op. cit*.).

Ávila et al. (*op. cit*.) reported four clutches from female *T. brongersmianus* originating from the Pantanal of Mato Grosso, Brazil. Clutch size averaged 4.67 eggs (range 4–5) and averaged 4.11 mm in length and 8.27 mm in width. The eggs reported here are 172% larger and 215% broader than those reported by Ávila et al. (*op. cit*.), perhaps reflecting geographic variation in reproductive strategy and/or local environmental conditions.

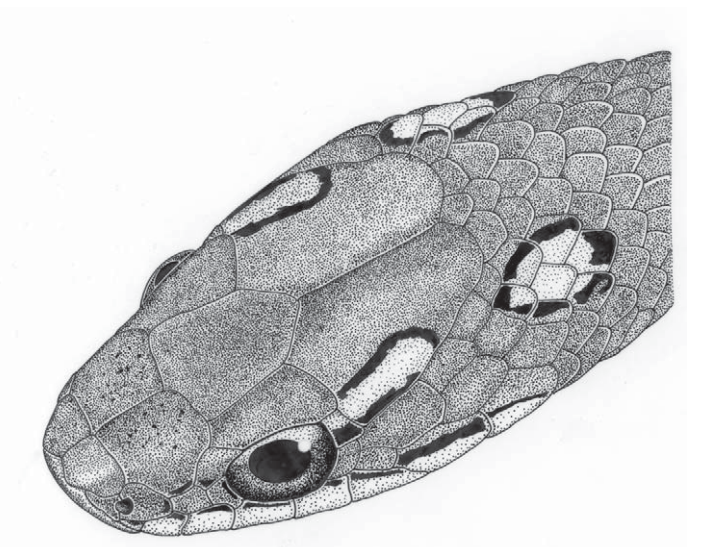
We thank G. E. Iack-Ximenes, A. Argôlo, and I. R. Dias for assistance. IBAMA issued the collecting permit (003/07 – IBAMA/RAN).

Submitted by **EUVALDO MARCIANO JUNIOR, JULIANA ALVES DE JESUS,** and **MIRCO SOLÉ** (e-mail: mksole@uesc.br), Universidade Estadual de Santa Cruz (UESC), Departamento de Ciências Biológicas, Rodovia Ilhéus-Itabuna, km 16, Salobrinho, CEP 45662-000, Ilhéus, BA, Brazil.

VIRGINIA VALERIAE VALERIAE (Eastern Smooth Earthsnake). **PREDATION**. Although many North American raptors include reptiles in their diets, reports of predation on snakes by passerine birds other than shrikes (Laniidae) and corvids are relatively uncommon (Ross 1989. Amphibians and Reptiles in the Diets of North American Raptors. Wisconsin Endangered Species Report No. 59). Most such incidents involve relatively large or mid-sized ground foragers such as thrashers (Browning 1973. Chat 37:107) and thrushes (Davis 1969. Wilson Bull. 81:471; Erickson 1978. Murrelet 59:26; Palmer and Braswell 1995. Reptiles of North Carolina. Univ. North Carolina Press, Chapel Hill. 412 pp.).

At ca. 1700 h on 31 January 2009, at Howell Woods, ca. 14 km ESE of Four Oaks, Johnston Co., North Carolina, USA (35.371°N, 78.307°W; datum WGS84), CEM heard rustling in the leaf litter 10 m away from and below his elevated position 5 m off the ground. The air temperature was ca. 6°C with a light wind (5–10 mph). Approximately 20 sec later, a Tufted Titmouse (*Baeolophus bicolor*) perched at the spot of the rustling in a small plant just above the ground surface. The bird then flew straight up to a tree branch ca. 5 m above the ground, carrying what later was identified as a *Virginia v. valeriae*. The titmouse immediately began pecking the snake and continued for 60 sec. The bird then flew to a branch 25 m above the ground while still carrying the snake, and resumed the pecking behavior. Between 5 and 10 min later, the bird was observed perched at the same spot, but without the snake. It swiped its bill as birds often do following predation. At ca. 1820 h, CEM scanned the area beneath the perch and located the remains of the snake. The head had been completely removed and punctures, likely from the bird's bill and claws, were scattered over the snake's body. The remains of the snake measured 19.69 cm in total length and weighed 2.1g.

This observation is particularly interesting because the Tufted Titmouse is such a small bird—averaging 17 cm long, 20 g in weight (Grubb and Pravosudov 1994. *In* A. Poole [ed.], The Birds of North America Online. Cornell Lab of Ornithology, Ithaca, New York; http://bna.birds.cornell.edu.www.lib.ncsu.edu:2048/bna/species/086). It eats primarily arthropod (e.g., caterpillars, beetles, ants, wasps, spiders, and scale insects) and vegetable foods, and typically forages by gleaning foliage and probing bark crevices (Grubb and Pravosudov, *op. cit*.). Although titmice generally forage in high vegetation, they may also spend considerable time feeding on or near the ground, especially on cold, windy days (Grubb and Pravosudov, *op. cit*.). To our knowledge, this represents the first report of a titmouse, or any similarly-sized passerine, as a predator of *V. valeriae*. The specimen is deposited in the North Carolina State Museum of Natural Sciences (NCSM 75790). It also represents a new county record and an early date of activity for the species in North Carolina (Palmer and Braswell, *op. cit*.).



Submitted by **CHRISTOPHER E. MOORMAN**, Fisheries and Wildlife Sciences Program, Department of Forestry and Environmental Resources, North Carolina State University, Raleigh, North Carolina 27695, USA (e-mail: chris_moorman@ncsu.edu); and **JEFFREY C. BEANE**, North Carolina State Museum of Natural Sciences, Research Laboratory, MSC # 1626, Raleigh, North Carolina 27699-1626, USA (e-mail: jeff.beane@ncdenr.gov).

XENOPHOLIS SCALARIS (Wucherer's Ground Snake). **DIET**. *Xenopholis scalaris* is believed to be a predatory specialist of frogs and its diet is known to be composed of *Adenomira andreae*, *Eleutherodactylus* species, *Hamptophryne boliviana*, and *Ischnocnema quixensis* (Duellman 1978. Univ. Kansas Nat. Hist. Mus. Misc. Publ. No. 65; Duellman 2005. Cusco Amazónico. Cornell University Press, Ithaca, New York. 433 pp.; Martins and Oliveira 1998. Herpetol. Nat. Hist. 6:78–150). Here we report an additional anuran food item for the species.

On 26 December 2007 an adult *X. scalaris* was observed and photographed consuming a subadult *Leptodactylus didymus* at Reserva Amazónica, Peru (UTADC 1954–55). The snake was found with the left leg of the anuran in its mouth. Over the next few minutes the snake engulfed the frog with its mouth, however the final ingestion of the prey item was not observed. The *L. didymus* was distinguished from *L. bolivianus*, also found at Reserva Amazónica, by having a creamy white longitudinal stripe across the thighs (Duellman 2005, *op. cit.*). Reserva Amazónica occurs in the Provincia Tambopata, ca. 12 km E of Puerto Maldonado on the north shore of the Rio Madre de Dios in southeastern Peru (ca. 12.5416667°N, 69.0527778°W; datum WGS 84; elev. 195 m). During our surveys from 18 December 2007 to 9 January 2008 we found *L. didymus* to be the most common anuran encountered. In addition, three *X. scalaris* were observed during surveys and the abundance of *L. didymus* may represent a large part of the prey base for *X. scalaris* in the area.

We thank J. A. Campbell for cataloguing the photograph and Jose Koechlin and Inkaterra for logistical support.

GEOGRAPHIC DISTRIBUTION

Herpetological Review publishes brief notices of new geographic distribution records in order to make them available to the herpetological community in published form. Geographic distribution records are important to biologists in that they allow for a more precise determination of a species' range, and thereby permit a more significant interpretation of its biology.

These geographic distribution records will be accepted in a **standard format** only, and all authors *must* adhere to that format, as follows: SCIENTIFIC NAME, COMMON NAME (for the United States and Canada as it appears in Crother [ed.] 2008. *Scientific and Standard English Names of Amphibians and Reptiles of North America North of Mexico*. SSAR Herpetol. Circ. 37:1–84, gratis PDF available (http://www.ssarherps.org/pages/HerpCommNames.php); for Mexico as it appears in Liner and Casas-Andreu 2008, *Standard Spanish, English and Scientific Names of the Amphibians and Reptiles of Mexico.* Herpetol. Circ. 38:1–162), LOCALITY (use metric for distances and give precise locality data, including lat/long coordinates in **decimal degrees** and cite the map datum used), DATE (day-month-year), COLLECTOR, VERIFIED BY (*cannot* be verified by an author; curator at an institutional collection is preferred), PLACE OF DEPOSITION (where applicable, use standardized collection designations as they appear in Leviton et al. 1985, *Standard Symbolic Codes for Institutional Resource Collections in Herpetology and Ichthyology,* Copeia 1985[3]:802–832) and CATALOG NUMBER (required), COMMENTS (brief), CITATIONS (brief and must adhere to format used in this section; these should provide a geographic context for the new record), SUBMITTED BY (give name and address in full—spell out state or province names—no abbreviations). Please include distance from nearest previously known record (provide a citation or refer to existing vouchered material to substantiate your report). If publishing specific locality information for a rare or endangered species has the potential to jeopardize that population, please consult with the Section Editor at time of record submission. If field work and/or specimen collection occurred where permits were required, please include permit number(s) and authorizing agency in the text of the note.

Some further comments. The role of the "Standard Names" lists (noted above) is to standardize English names and comment on the current scientific names. Scientific names are hypotheses (or at least represent them) and as such their usage should not be dictated by a list, society, or journal.

Additionally, this geographic distribution section does not publish "observation" records. Records submitted should be based on preserved specimens that have been placed in a university or museum collection (private collection depository records are discouraged; institutional collection records will receive precedence in case of conflict). A good quality photograph (print, slide, or digital file) may substitute for a preserved specimen *only* when the live specimen could not be collected for the following reasons: it was a protected species, it was found in a protected area, or the logistics of preservation were prohibitive (such as large turtles or crocodilians). Photographic vouchers *must* be deposited in a university or museum collection along with complete locality data, and the photographic catalog number(s) must be included in the same manner as a preserved record. Before you submit a manuscript to us, check Censky (1988, *Index to Geographic Distribution Records in Herpetological Review: 1967–1986*; available from the SSAR Publications Secretary), subsequent issues of *Herpetological Review*, and other sources to make sure you are not duplicating a previously published record. The responsibility for checking literature for previously documented range extensions lies with authors. **Do not submit range extensions unless a thorough literature review has been completed.**

Please submit any geographic distribution records in the **standard format only** to one of the Section Co-editors: **Alan M. Richmond** (USA & Canada records only); **Jerry D. Johnson** (Mexico and Central America, including the Caribbean Basin); **Indraneil Das** (all Old World records); or **Gustavo J. Scrocchi** (South American records). Short manuscripts are discouraged, and are only acceptable when data cannot be presented adequately in the standard format. **Electronic submission of manuscripts is required** (as Microsoft Word or Rich Text format [rtf] files, as e-mail attachments)**.** Refer to inside front cover for e-mail addresses of section editors.

Recommended citation for new distribution records appearing in this section is: Schmitz, A., and T. Ziegler. 2003. Geographic distribution: *Sphenomorphus rufocaudatus*. Herpetol. Rev. 34:385.

CAUDATA – SALAMANDERS

NOTOPHTHALMUS VIRIDESCENS VIRIDESCENS (Red-spotted Newt). USA: OHIO: Belmont Co.: Wayne Township, Raven Rock (39.88036°N, 81.04077°W; WGS 84). 04 April 2006. Cincinnati Museum Center (CMC 8957–8958). Vouchers for a second Belmont Co. location were also obtained (CMC 8998–8999). Shelby Co.: Washington Township, Lockington Preserve (40.21596°N, 84.25667°W; WGS 84). 12 August 2008. CMC 11283. All material collected by Jeffrey G. Davis and Greg Lipps Jr. and verified by John W. Ferner. First county records (Pfingsten and Matson 2003. Ohio Salamander Atlas, Ohio Biological Survey Misc. Contrib. No. 9, Columbus).

Submitted by **JEFFREY G. DAVIS**, Cincinnati Museum Center – Fredrick and Amye Geier Research and Collections Center, 1301 Western Avenue, Cincinnati, Ohio 45203-1130, USA (e-mail: anura@fuse.net); and **GREG LIPPS JR.**, 1473 County Road 5-2, Delta, Ohio 43515, USA (e-mail: GregLipps@aol.com).

SALAMANDRA SALAMANDRA (Fire Salamander). HUNGARY: BUDAPEST: Pesthidegkút (47.34ºN, 18.56ºE; elev. 260 m). 01 June 2009. Gábor Szelényi. Verified by Judit Vörös, Hungarian Natural History Museum (HNHM 2009.2.1). First county record. Species previously known from Budapest Hills (Méhely 1918. Fauna Regni Hungariae [Reptilia et Amphibia]. Királyi Magyar Természettudományi Társulat 13 pp.), but report did not specify locality. No specimens had been observed in the area since 1918. Adult specimen collected close to stream in forested valley surrounded by buildings and roads.

Submitted by **GÁBOR SZELÉNYI**, Middle-Danube-Valley Inspectorate for Environmental Protection, Nature Conservation and Water Management, 1072 Budapest, Nagydiófa u. 10–12, Hungary; **ISTVÁN KISS**, Szent István University, Department of Zoology and Animal Ecology, 2100 Gödöllő, Páter K. u. 1, Hungary (e-mail: kiss.istvan@mkk.szie.hu); and **JUDIT VÖRÖS**, Hungarian Natural History Museum, 1088 Budapest, Baross u. 13, Hungary.

ANURA – FROGS

ACRIS CREPITANS (Northern Cricket Frog). USA: ARKANSAS: Woodruff Co.: near Brushy Lake Road on Cache River National Wildlife Refuge, 0.2 mi. S of AR 260 W (35.22372ºN, 91.25617ºW; WGS84; elev. 60 m). 25 Oct 2009. Thomas J. Belford. University of Kansas Natural History Museum photo voucher (KUDA 9109). Verified by William E. Duellman. Four specimens were found in a grassy flooded ditch. First county record. Extends range ca. 29 km from nearest known record in White Co., Arkansas. (Trauth et al. 2004. The Amphibians and Reptiles of Arkansas. Univ. Arkansas Press. Fayetteville. 421 pp.)

Submitted by **THOMAS J. BELFORD,** 701 West Academy Avenue, Searcy, Arkansas 72143, USA; e-mail: thomasbelfordiniraq@yahoo.com.

ACRIS CREPITANS (Northern Cricket Frog). USA: TENNESSEE: Lawrence Co.: Tennessee Amphibian Monitoring Program (TAMP) Route 820513, Stop 10, Dry Creek Rd. 0.39 km S of intersection with County Line Rd (35.43605°N, 087.22462°W;

WGS84). 15 May 2007. Brian Stewart. Verified by A. Floyd Scott. Austin Peay State University Museum of Zoology (APSU audio). New county record (Redmond and Scott 1996. Austin Peay St. Univ. Center Field Biol. Misc. Publ. 12:1–94).

Submitted by **BRIAN STEWART**, 850 Lion Parkway, Columbia, Tennessee 38401, USA.

ANAXYRUS WOODHOUSII (Woodhouse's Toad). USA: COLORADO: Chaffee Co.: Ute Creek drainage north of Salida (38.54967°N, 106.00728°W; NAD 83; elev. 2150 m), 14 September 2009. Raquel Stotler and Heather Adams. Verified by Lauren J. Livo. Photograph deposited in the Ancillary Collection of the University of Colorado Museum, Boulder, Colorado (UCM-AC 171). First county record. Extends range along Arkansas River northwest ca. 11 km from Wellsville record in Fremont Co. (Hammerson 1999. Amphibians and Reptiles in Colorado, 2nd ed. University Press of Colorado, Niwot. xxvii +484 pp.).

Submitted by **RAQUEL STOTLER**, Colorado Division of Wildlife, 7405 U.S. Highway 50, Salida, Colorado 81201, USA; e-mail: Raquel.Stotler@state.co.us.

CHIASMOCLEIS ALAGOANUS (NCN). BRAZIL: PERNAMBUCO: Municipality of São Lourenço da Mata: Engenho Tapacurá **(**08.014522ºS, 35.087728ºW; WGS 84; elev. 153 m). 27 September 2006. E. M. dos Santos and F. O. de Amorim. Coleção Herpetológica da Universidade Federal Rural de Pernambuco, Unidade Acadêmica de Serra Talhada, Serra Talhada, Pernambuco, Brazil (CHUFRPE 972, adult specimen SVL 26.4 mm). Verified by M. A. Freitas. First state record. Previously known from the type locality: Mata do Catolé, Municipality of Maceió, state of Alagoas (Cruz et al. 1999. J. Zool., London 249:123); and Mata do Buraquinho, municipality João Pessoa, state of Paraiba (Vieira et al. 2008. Biotemas 21[1]:75–84). Extends the known distribution 195 km N from type locality and 100 km S from municipality of João Pessoa.

Submitted by **EDNILZA MARANHÃO DOS SANTOS,** Unidade Acadêmica de Serra Talhada, Universidade Federal Rural de Pernambuco, 56900-000, Serra Talhada, PE, Brazil; and **FABIANA OLIVEIRA DE AMORIM,** Rua Eng. Gercino de Pontes, n.129, apto.101, Iputinga, 50800-110, Recife-PE, Brazil.

CHIROMANTIS DORIAE (Doria's Bush Frog). BANGLADESH: SYLHET DIVISION: Maulvibazar District, Sreemangal, Lawachara National Park (24.3306333ºN, 91.793°E). 12–13 June 2008. M. K. Hasan. Jahangirnagar University Herpetological Group, Department of Zoology, Jahangirnagar University, Savar, Dhaka, Bangladesh (JUHG 0292–0296). Verified by S. D. Biju. First country record for Bangladesh. Nearest locality record, from Namdapha Tiger Reserve, Arunachal Pradesh, NE India, is ca. 630 km NE of this locality (Pawar and Birand. 2001. CERC Tech. Rep. [6]:1–118). Males observed calling between 1950–2015 h from foliage of climbing plants, on wall bordering railroad track that transects mature secondary forested area. Numerous foam nests observed on underside of leaves overhanging small, stagnant water body, at base of wall.

Collection permit issued by Bangladesh Forest Department (CCF[wildlife]/2M–37[part 3]/2007/1047). MKH and MFK would like to thank Mushfiq Ahmed for lab assistance and SM would like to thank Barry Clarke (BMNH) for permitting access to collections.

Submitted by **MD. GASTROPHRYNE OLIVACEA (Western Narrow-mouthed Toad). USA: NEBRASKA: Webster Co.: 8.0 km S Red Cloud (40.017017°N, 98.51895°W; NAD 83). 21 and 23 July 2008. Keith Geluso and Greg D. Wright. Verified by Thomas E. Labedz, University of Nebraska State Museum, Lincoln, Nebraska (UNSM ZM 23866–23867). New county record. Represents only second county in Nebraska with observations. Previous records reported from Gage Co. (Lynch 1985. Trans. Nebraska Acad. Sci. 13:33–57). Multiple individuals observed at night feeding on tiny ants on moderately vegetated slopes with small limestone rocks. An additional specimen from this location was collected on 03 June 1985 (UNSM ZM 8814).

Submitted by **KEITH GELUSO** (e-mail: gelusok1@unk.edu) and **GREG D. WRIGHT**, Department of Biology, University of Nebraska–Kearney, Kearney, Nebraska 68849, USA.

HYLA CINEREA (Green Treefrog). USA: TENNESSEE: McNairy Co.: Finger, 294 Sherry Lynn Drive (35.357800˚N, 88.635583˚W; datum WGS84). 22 September 2009. Brian P. Butterfield and Joseph B. Butterfield. Verified by A. Floyd Scott. Austin Peay State University Museum of Zoology (APSU 18975 color photo). First county record. Specimen was collected on the inside wall of a garage in a rural, residential subdivision located in an oak/hickory forest. (Redmond and Scott 1996. Atlas of Amphibians in Tennessee. Misc. Publ. No. 12. Center for Field Biology, Austin Peay State University, Clarksville, Tennessee. 94 pp. Hard copy and Internet versions [http://www.apsu.edu/amatlas/]. Accessed 23 October 2009). Collection was made under the authority of Tennessee Wildlife Resources Agency Permit 1494.

Submitted by **BRIAN P. BUTTERFIELD**, Department of Biology, Freed-Hardeman University, Henderson, Tennessee 38340, USA (e-mail: bbutterfield@fhu.edu); and **JOSEPH B. BUTTERFIELD**, 294 Sherry Lynn Drive, Finger, Tennessee 38334, USA.

ISCHNOCNEMA OCTAVIOI (Octavio's Robber Frog). BRAZIL: ESPÍRITO SANTO STATE: Matilde, Municipality of Alfredo Chaves (20.330306ºS, 40.480560ºW; datum: Córrego Alegre; elev. 632 m). 22 July 2008. R. B. Dantas. Zoology Collection, Museu de Biologia Mello Leitão, Santa Teresa, Espirito Santo, Brazil (MBML 6762). Verified by G. M. Prado). First state record, extends range ca. 258 km NE from Casimiro de Abreu municipality, Rio de Janeiro state. Previously known only from Brazil, in the state of Rio de Janeiro (Vrcibradic et al. 2008. Check List 4:103–106).

Submitted by **ROBERTO DE BARROS DANTAS** (e-mail: dantasbio@hotmail.com); and **RODRIGO BARBOSA FER-**

REIRA (e-mail: rodrigoecologia@yahoo.com.br), Museu de Biologia Mello Leitão, Av. José Ruschi, Nº 4, CEP 29.650-000, Santa Teresa, Espírito Santo, Brazil.

LEPTODACTYLUS FRAGILIS (White-lipped Frog). MÉXICO: OAXACA: Municipality of Santiago Jamiltepec, Atotonilco (16.189444°N, 97.819722°W; WGS 84), 68 m elev. 01 January 2006. Aurelio Ramíez-Bautista and Vicente Mata-Silva. Verified by Uriel Hernández-Salinas. Colección Herpetológica del Centro de Investigaciones Biológicas, Universidad Autónoma del Estado de Hidalgo (CIB 2498–2503). First municipality records. Fill a gap between the closest reported localities ca. 210 km WNW near Acapulco, Guerrero (Flores Villela et al. 1991. Serie Cat. Mus. Zool. "Alfonso L. Herrera" Cat. [3]:1–222) and ca. 270 km ENE of several records in the vicinity of Tehuantepec, Oaxaca (Hartweg and Oliver 1940. Misc. Publ. Mus. Zool. Univ. Michigan [47]:1–31; Duellman 1960. Univ. Kansas Publ. Mus. Nat. Hist. 13:19–72). Casas-Andreu et al. (2004. *In* Garcia-Mendoza et al. [eds.], Biodiversidad de Oaxaca, pp. 375–390. Inst. Biol. UNAM, Mexico D.F.) reported that this species occurs in floristic-faunistic areas 9 and 10 in the eastern portion of Oaxaca. These animals were found within floristic-faunistic area 8 in the southern coastal/foothills region. The frogs were found swimming along the cooler periphery of a hot spring.

TESTUDINES – TURTLES

CHRYSEMYS PICTA (Painted Turtle). USA: NEBRASKA: Furnas Co.: 0.3 km W, 5.0 km S Oxford (40.207183°N, 99.63923°W; NAD 83). 27 June 2009. Keith Geluso and Owen J. Johnson. Verified by Curtis J. Schmidt, Sternberg Museum of Natural History, Hays, Kansas (MHP 14675). New county record. Known from adjacent Red Willow County to the west (Lynch 1985. Trans. Nebraska Acad. Sci. 13:33–57). Found dead on road.

Submitted by **KEITH GELUSO** (e-mail: gelusok1@unk.edu) and **OWEN J. JOHNSON**, Department of Biology, University of Nebraska–Kearney, Kearney, Nebraska 68849, USA

CUORA AMBOINENSIS KAMAROMA (Malayan Box Turtle). PHILIPPINES: BALABAC: Barangays: Agutayan, Catagupan, Melville, Indalawan, and Salang; rice paddies near Basak Creek, Timbangan, Saray, Lagdong, Busay, and Baoang Creek. February 10–25 2007. P. Fidenci. California Academy of Sciences photo vouchers (CAS-HPV 48–54). Verified by Hallie Brignall. First records for Balabac (Diesmos et al. 2008. *Chelonian Conserv. Biol.* 7:157–177). One adult observed at rice paddies near Basak Creek, two adults at Timbangan Creek, one adult at Saray Creek, one adult in Lagdong Creek, three juveniles at Busay Creek, and two adults at Baoang Creek.

Submitted by **PIERRE FIDENCI**, Endangered Species International, 79 Brady St, San Francisco, California 94103, USA; e-mail: pfidenci@endangeredspeciesinternational.org.

GRAPTEMYS GEOGRAPHICA (Common Map Turtle). USA: INDIANA: Lawrence Co.: Buddha Bypass Bridge south of Buddha (38.7704250°N, 86.4093305°W; no datum available). 30 July 2008. Peter V. Lindeman. Verified by John B. Iverson. Florida Museum of Natural History Herpetology Dept. photographic archive (UF 153477). New county record (Minton 2001. Amphibians & Reptiles of Indiana, 2nd ed. Indiana Academy of Science, Indianapolis. 404 pp.). Basking adult female.

Submitted by **PETER V. LINDEMAN**, Department of Biology and Health Services, 150 Cooper Hall, Edinboro University of Pennsylvania, Edinboro, Pennsylvania 16444, USA; e-mail plindeman@edinboro.edu.

GRAPTEMYS GIBBONSI (Pascagoula Map Turtle). USA: MISSISSIPPI: Pike Co.: Bogue Chitto River, 50 m upstream of Route 98 bridges (31.1773722°N, 90.2795194°W; no datum available). 25 May 2008. Peter V. Lindeman. Florida Museum of Natural History Herpetology Dept. photographic archive (UF 153478). Verified by Will Selman. New county record (Cliburn 1971. J. Mississippi Acad. Sci. 16:16–19), extending known range in the Bogue Chitto upstream by ca. 10 river km. Basking juvenile.

Submitted by **PETER V. LINDEMAN**, Department of Biology and Health Services, 150 Cooper Hall, Edinboro University of Pennsylvania, Edinboro, Pennsylvania 16444, USA; e-mail: plindeman@edinboro.edu.

GRAPTEMYS OUACHITENSIS (Ouachita Map Turtle). USA: INDIANA: Lawrence Co.: Buddha Bypass Bridge south of Buddha (38.7704250°N, 86.4093305°W; no datum available). 31 July 2008. Peter V. Lindeman. Verified by John B. Iverson. Florida Museum of Natural History Herpetology Dept. photographic archive (UF 153479). New county record (Minton 2001. Amphibians & Reptiles of Indiana, 2nd ed. Indiana Academy of Science, Indianapolis. 404 pp.). Basking adult female.

Submitted by **PETER V. LINDEMAN**, Department of Biology and Health Services, 150 Cooper Hall, Edinboro University of Pennsylvania, Edinboro, Pennsylvania 16444, USA; e-mail: plindeman@edinboro.edu.

GRAPTEMYS OUACHITENSIS (Ouachita Map Turtle). USA: MINNESOTA: Dakota Co.: Pool 2 of the Mississippi River at approximately river mile 827 (44.8127°N, 093.009118°W; datum NAD83). 30 May 2009. Richard McCarthy. Verified by Kenneth Kozak and Amy Luxbacher. James Ford Bell Museum (photographic vouchers JFBM P317–P319). New county record (Oldfield and Moriarty 1994. Amphibians and Reptiles Native to Minnesota. University of Minnesota Press, Minneapolis. 233 pp.). Three individuals observed in slough and on adjacent mound in protected area bordering Pool 2. Northernmost known occurrence on Mississippi River. Species may have reoccupied Pool 2 following water quality improvements in recent decades.

Submitted by **RICHARD McCARTHY**, Macalester College Ordway Natural History Study Area, 9950 Inver Grove Trail, Inver Grove Heights, Minnesota 55076, USA; e-mail: rmccarth@macalester.edu.

SQUAMATA – LIZARDS

ACRATOSAURA MENTALIS (NCN). BRAZIL: RIO GRANDE DO NORTE: Municipality of Tenente Laurentino Cruz, Serra Nova (06.109°S, 36.719°W; datum WGS84; elev. 704 m). 24 October 2009. M. Gogliath. Coleção Herpetológica do Departamento de Botânica, Ecologia e Zoologia, Universidade Federal do Rio Grande do Norte, Natal, Rio Grande do Norte (CHBEZ 2930). Verified by M. T. Rodrigues. First record in the state of Rio Grande do Norte, and extends the known geographical distribution of this species ca. 135 km N from the nearest record in the municipalities of São José dos Cordeiros/Sumé (Reserva Particular do Patrimônio Natural Fazenda Almas) (07.471°S, 36.881°W), state of Paraíba. According to Rodrigues (1986. Pap. Avul. Zool. 36[20]:237–250), *Acratosaura mentalis* has a disjunct distribution and has been found in Senhor do Bonfim (type locality), Mucugê (Freitas and Silva 2007. Guia Ilustrado: A Herpetofauna das Caatingas e áreas de Altitudes do Nordeste Brasileiro. Editora USEB, Pelotas, Bra-

zil. 384 pp.) and Maracás (Rodrigues et al. 2007. Am. Mus. Nov. 3565:1–27), state of Bahia; Grão Mogol (Rodrigues 1986, *op. cit.*) in the state of Minas Gerais; Estação Ecológica de Xingó, states of Alagoas/Sergipe (Bandeira 2000. Aspectos Zoogeográficos e Ecológicos da Saurofauna da Estação Ecológica de Xingó, AL/SE. Monograph, Universidade Federal de Alagoas, Maceió, Brazil. 35 pp.); Brejo da Madre de Deus, Pernambuco State (Queiroz and Lema 1996. Biociências 4[1]:87–90); Cabaceiras (Rodrigues 1986, *op. cit.*), Cacimba de Dentro (Arzabe et al. 2005. *In* Araújo et al. [orgs.], Herpetofauna da área do Curimataú, Paraíba, pp. 264–280. Ministério do Meio Ambiente, Brasília, Brazil), São José dos Cordeiros and Sumé (Reserva Particular do Patrimônio Natural Fazenda Almas; Delfim and Freire 2007. Oecol. Bras. 11[3]:365–382; Freire et al. 2009. *In* Freire [org.], Répteis das Caatingas do Seridó do Rio Grande do Norte e do Cariri da Paraíba: Síntese do Conhecimento Atual e Perspectivas, pp. 51–84. Editora Universitária da UFRN, Natal, Brazil), state of Paraíba.

We thank the municipal government of Tenente Laurentino Cruz for logistical support.

AGAMA AGAMA AFRICANA (African Rainbow Lizard). USA: FLORIDA: Duval Co.: 15981 Croaker Road, Jacksonville (30.5285°N, 81.4820°W; WGS84). 07 August 2009. David Hoffer. Florida Museum of Natural History photographic voucher (UF 155901). Verified by Kenneth L. Krysko. First county record. Extends range ca. 195 km N of a population in Seminole Co. (Enge et al. 2004. Florida Sci. 67:303–310). Adult male observed on a pile of slate. Other individuals of different sizes have been observed on the property since 2008, indicating a potential breeding population of unknown provenance. This nonnative species has now been recorded from 10 counties in Florida.

Submitted by **KEVIN M. ENGE**, Florida Fish and Wildlife Conservation Commission, 1105 SW Williston Road, Gainesville, Florida 32601, USA (e-mail: kevin.enge@myfwc.com); **CHUCK HUBBUCH**, University of North Florida, 1 UNF Drive, Jacksonville, Florida 32224; and **DAVID HOFFER**, 15981 Croaker Road, Jacksonville, Florida 32226, USA.

CHALCIDES SEXLINEATUS BISTRIATUS (NCN). SPAIN: CANARY ISLANDS: La Palma Island, Tazacorte, La Florida (28.639326°N, 17.928760°W; datum: WGS84; elev. 158 m). 08 September 2008, Two adults and two juveniles deposited in collection of Department of Animal Biology of La Laguna University (adults: DZUL 3018–3019; juveniles: DZUL 3020–3021). Verified by A. Martín. Species endemic to northern Gran Canaria Island. At least 60 individuals were brought to La Palma Island over 50 years ago. At the time, the species was absent from the island (Izquierdo et al. 2004. Lista de Especies Silvestres de Canarias [Hongos, Plantas y Animales Terrestres]. Gobierno de Canarias, Santa Cruz de Tenerife. 497 pp.). Presence of juveniles suggests an established population. This species appears to occur over a small area (ca. 4 ha) dominated by intensive banana cultivation. Both native and introduced predators such as kestrels (*Falco tinnunculus*), lizards (*Gallotia* spp.), and feral cats (*Felis silvestris catus*) are known to eat skinks (Santana et al. 1986. Vierarea 16:113–117; Barbadillo 1987. La Guía Incafo de los Anfibios y Reptiles de la Península Ibérica, Islas Baleares y Canarias. Incafo, S.A., Madrid). These facts, together with the proximity of this population to villages and roads could affect the possible spread of the species to the rest of the island.

I thank A. Martín and M. Nogales for suggestions on the manuscript and J. A. Campbell for editorial assistance.

CHALCIDES VIRIDANUS (West Canary Skink). SPAIN: CANARY ISLANDS: La Palma Island: Los Llanos de Aridane (28.639326ºN, 17.928760ºW, datum: WGS84; elev. 158 m). 08 September 2008. Department of Animal Biology of La Laguna University, DZUL 3022. Verified by A. Martín. First island record with location data. Endemic to Tenerife Island, and probably introduced through wood commerce between both islands of the Canarian Archipelago, and absent on La Palma Island (Izquierdo et al. 2004. Lista de Especies Silvestres de Canarias [Hongos, Plantas y Animales Terrestres]. Gobierno de Canarias, Santa Cruz de Tenerife. 497 pp.). This is the second record for this species on the island (Mateo 2002. *In* Pleguezuelos et al. [eds.], Atlas y Libro Rojo de los Anfibios y Reptiles de España, pp. 173–174. Dirección General de Conservación de la Naturaleza – Asociación Herpetológica Española, Madrid.

DAREVSKIA BRAUNERI SZCZERBAKI (Rock Lizard). GEORGIA: REPUBLIC OF ABKHAZIA: Gudauta District: Lzaa village, Pitsunda-Myussera Hills (Herpetological Collection of Zoological Institute, St. Petersburg, ZISP 24397, 25816–25818). Verified by Ilya S. Darevsky. First country record. 17 April 2006. Konstantin Milto and Mark Pestov. Additional specimens were seen on 5–7 July, 7–9 August 2008, and 7–12 August 2009 by Mark Pestov and Olga Bezman-Moseyko. Lizards were encountered on the clay-rock cliffs of the Black Sea coast between Lzaa settlement (43.16813ºN, 40.4108ºE) and mouth of Mysra River (43.15009ºN, 40.45921ºE). The previously known distribution of *Darevskia brauneri szczerbaki* is limited to a small territory on the northeastern coast of the Black Sea in Krasnodar Region, Russia. This subspecies is endemic of Crimea-Novorossisk subprovince of the East Mediterranean Province in Caucasus and inhabits a narrow coastral zone from Anapa town to the Cape of Utrish. New record is 297 km SE of previously documented locations. The Myussera Hills are probably the southernmost border of *D. b. szczerbaki* distribution.

Submitted by **KONSTANTIN D. MILTO** (e-mail: coluber@zin.ru)**, MARK V. PESTOV,** and **OLGA S. BEZMAN-MOSEYKO,** Zoological Institute, Department of Herpetology, St. Petersburg, Universitetskaya emb., 1, 199034, Russia.

HELODERMA SUSPECTUM CINCTUM (Banded Gila Monster). USA: CALIFORNIA: San Bernardino Co.: Mojave National Preserve: Vulcan Mine (34.55353ºN, 115. 35160ºW; WGS 84; elev. 1077m). 02 May 2009, 1615 h, 24ºC air, 420 mm total length. Ron M. Ruppert. Verified by K. Beaman. Natural History Museum of Los Angeles County voucher photographs (LACM-PC 1461–1466).

There are only 26 records of *Heloderma suspectum* from California over the past 153 years. The most recent photographic documentation from the Vulcan Mine area was 1968. The most recent record in California was 2006 from an area 100 km to the north of Vulcan Mine (Lovich and Beaman 2007. Bull. So. California Acad. Sci.106[2]:39–58).

HEMIDACTYLUS FRENATUS (Common House Gecko). MEXICO: BAJA CALIFORNIA SUR: Municipality of Comondú: Ciudad Constitución, Hotel Oasis (25.036472º N, 111.6795º W; WGS84; elev. 54 m) 25 October 2008. J. B. Granados. Verified by Oscar Flores-Villela. Herpetological collection of the Centro de Investigaciones Biológicas del Noroeste, La Paz, Baja California Sur, México (CIBNOR 0721–22). First records for the municipality. Bridges a distributional gap between La Paz (208 km SE) and Loreto (149 km NE) (Grismer 2002. Amphibians and Reptiles of Baja California: Including its Pacific Islands and the Islands in the Sea of Cortez. Univ. California Press, Berkeley, California. 399 pp.). Both juveniles were collected at night on the hotel wall, and because adults were also observed from the same location, this exotic species is assumed to be well-established there.

Submitted by **VÍCTOR H. LUJA** (e-mail: lujastro@yahoo.com), **JAVIER BRUNO GRANADOS**, and **RICARDO RODRÍGUEZ-ESTRELLA**, Centro de Investigaciones Biológicas del Noroeste (CIBNOR), Mar Bermejo #195 Colonia Playa Palo de Santa Rita, La Paz, Baja California Sur, 23090, México.

HEMIDACTYLUS MABOUIA (Wood Slave). USA: FLORIDA: St. Lucie Co.: Fort Pierce, 2100 Elizabeth Avenue (27.40840ºN, 80.34595ºW; WGS 84). 11 May 2009. Ken Hibbard. Verified by Kenneth L. Krysko. Florida Museum of Natural History, University of Florida (UF 155444). First county record. One adult female, heavily infested with ectoparasitic pterygosomatid mites, was collected from a porch screen of a residence at 2200 h. Three other individuals were observed at this same locality at 2000 h on 13 May 2009; they are common in sections of the Fort Pierce area. This invasive African species is currently the most widespread and rapidly spreading nonindigenous gecko in southern and central Florida (Meshaka et al. 2004. The Exotic Amphibians and Reptiles of Florida. Krieger Publ. Co., Malabar, Florida; Krysko and Daniels 2005. Caribb. J. Sci. 41:28–36), with a more recently established population in northern peninsular Florida (Krysko and Somma 2007. Herpetol. Rev. 38:352).

HEMIDACTYLUS TURCICUS (Mediterranean Gecko). USA: ARKANSAS: Union Co.: South Arkansas Community College, El Dorado (33.209186°N, 92.666117°W; WGS 84). 30 September 2009. W. Bibby. Verified by S. E. Trauth. Arkansas State University Museum of Zoology Herpetology Collection (ASUMZ 31385). First county record (Trauth et al. 2004. The Amphibians and Reptiles of Arkansas. University of Arkansas Press, Fayetteville. 421 pp.). This hatchling was found on the floor of the Whitfield Building on the campus of South Arkansas Community College. It has been previously collected in neighboring Columbia Co. (Fowler and Robison 2007. Herpetol. Rev. 38:218) and nearby Ouachita and Webster Parishes in Louisiana (Meshaka et al. 2006. Herpetol. Conserv. Biol. 1[1]:45–50).

Submitted by **MATTHEW B. CONNIOR,** Health and Natural Sciences, South Arkansas Community College, PO Box 7010, 300 South West Avenue, El Dorado, Arkansas 71731,USA; e-mail: mconnior@southark.edu.

MESOSCINCUS MANAGUAE (Managua Skink). GUATEMALA: ZACAPA: Municipality of Cabañas, El Arenal (14.8796°N, 89.7711°W; NAD27; elev. 410 m). 22 August 2004. Daniel Ariano-Sánchez and Gilberto Salazar. Verified by Carlos Vásquez and Theodore Papenfuss. Museo de Historia Natural de la Universidad de San Carlos de Guatemala (USAC 1128). Second record, but first documented locality for this species in Guatemala, extending the range ca. 5 km NE of an individual reported from Rosario, Guatemala (Acevedo 2006. Biodiversidad de Guatemala, Vol. 1. Univ. del Valle de Guatemala, Guatemala. 524 pp.), and ca. 110 km NW from the nearest confirmed record in Imposible National Park, El Salvador (YPM 12436). The lizard was found at 1100 h as it crawled through a dry gulley within tropical dry forest dominated by the columnar cacti, *Stenocereus pruinosus*, and the thorn shrub, *Mimosa zacapana*, a vegetation formation similar to that depicted by Köhler (2008. Reptiles of Central America. Herpeton, Verlag Elke Köhler, Offenbach, Germany. 400 pp.).

PLESTIODON FASCIATUS (Common Five-lined Skink). USA: FLORIDA: Clay Co.: Black Creek Ravines Conservation Area, 3.7 km E jct of State Road 21 and County Road 218 (30.0669°N, 81.8358°W; WGS84; 10 m elev.). Florida Museum of Natural History (UF 154255). Verified by Kenneth L. Krysko. New county record. 25 November 2008. Kevin M. Enge. Collected inside a large pine stump in mixed hardwood forest along a steephead stream ravine. Museum vouchers now exist for seven northern peninsular counties: Citrus, Clay, Columbia, Hamilton, Levy, Marion, and Suwannee. Ashton and Ashton (1991. Handbook of Reptiles and Amphibians of Florida. Part Two: Lizards, Turtles & Crocodilians. Windward Publ., Miami, Florida. 191 pp.) show eight additional peninsular counties, but the validity of their most southeasterly records from Volusia County is questionable. Specimens of *Plestiodon laticeps* with four labial scales anterior to the subocular scale on one side and five labials on the other side are sometimes mistakenly identified as *P. fasciatus*. In the Florida Museum of Natural History collection, the only purported specimens of *P. fasciatus* from Lafayette (UF 136039), St. Johns (UF 69883), and Taylor (UF 91096) counties were misidentified. Unverified reports exist for Baker, Bradford, and Taylor counties (see Enge 1997. A Standardized Protocol for Drift-fence Surveys. Florida Game Fresh Water Fish Comm. Tech. Rep. No. 14, Tallahassee).

PLESTIODON MULTIVIRGATUS EPIPLEUROTUS (Variable Skink). USA: TEXAS: Schleicher Co.: Eldorado, 12.9 air mi NW of jct U.S. Hwys 277 and 190, along Schleicher County Road 426 (30.94115ºN, 100.79705ºW; WGS 84) 2486 ft elev. 07 April 2006. M. S. Price and S. G. Price. Verified by Travis J. LaDuc (photographic voucher TNHC 7340100). First county record (Dixon 2000. Amphibians and Reptiles of Texas, 2nd ed. Texas A&M University Press. College Station, Texas. 421 pp.). Fills in distributional gap.

Submitted by **MICHAEL S. PRICE,** San Angelo Nature Center, 7409 Knickerbocker Road, San Angelo, Texas 76904, USA; e-mail: michael.price@sanangelotexas.us.

SCELOPORUS CYANOGENYS (Blue Spiny Lizard). USA: TEXAS: Kleberg Co.: Business Hwy 77 (State Loop 428), 0.65 road km NE from junction with FM 1355, below bridge overpass at intersection with San Fernando Creek (27.550267°N, 97.840796°W; WGS 84). Collected on 9 and 16 July 2009. Randy Powell, William Lukefahr, William Moore, and Robert Rabe. Verified by Travis J. LaDuc. Texas Natural History Collections (TNHC 78101–78102). Five additional specimens were captured at this location between 4 July and 11 August; the animals were measured, tagged with Passive Integrated Transponders (PIT), blood samples were taken, and they were released at the site. County record. An additional location within Kleberg County yielded two more specimens (TNHC 78103–78104). All specimens were caught in glue traps. The collection sites are ca. 1.6 air km apart and both are adjacent to San Fernando Creek and ca. 1.5–2 km S of the Nueces-Kleberg county line. Extends the range south one county (Dixon 2000. Amphibians and Reptiles of Texas, 2nd ed. Texas A&M Univ. Press. College Station. 421 pp.).

Submitted by **RANDY L. POWELL** (e-mail: randy.powell@tamuk.edu),**WILLIAM D. LUKEFAHR**, **WILLIAM L. MOORE**, and **ROBERT W. RABE**, Department of Biological and Health Sciences, MSC 158, Texas A&M University, Kingsville, Texas 78363, USA.

SCELOPORUS CYANOSTICTUS (Blue-spotted Spiny Lizard). MEXICO: NUEVO LEON: Municipality of Mina; 58.7 air km SW of Sabinas Hidalgo along Mex. Hwy 53 (26.24959ºN, 100.69002ºW; WGS84; elev. 785 m). 07 October 2007. Michael S. Price, Christopher R. Harrison, Travis J. Fisher, and David Lazcano. Verified by Hobart M. Smith. UANL 6987. First state record (Liner 2007. Occas. Pap. Mus. Nat. Sci. Louisiana St. Univ. [80]:1–59). A range extension of ca. 70 km E from the closest known locality in SW Coahuila (Lemos Espinal and Smith 2007. Anfibios y Reptiles del Estado de Coahuila, México. UNAM, Tlalnepantla, Estado de México and CONABIO, México, D.F. 550 pp.). The lizard was found in a boulder pile at the base of a north-facing canyon wall bounded by Chihuahuan Desert scrub vegetation.

Submitted by **MICHAEL S. PRICE**, San Angelo Nature Center, 7409 Knickerbocker Road, San Angelo, Texas 76904, USA (e-mail: michael.price@sanangelotexas.us); **CHRISTOPHER R. HARRISON**, Biology Department, Northwest Vista College, San Antonio, Texas 78251, USA (e-mail: crharrison@satx.rr.com);and **DAVID LAZCANO,** Universidad Autónoma de Nuevo León, Facultad de Ciencias Biológicas, Laboratorio de Herpetología, Apartado, Postal – 513, San Nicolás de los Garza, Nuevo León, C.P. 66450, México (e-mail: dlazcanov@hotmail.com).

SCELOPORUS JARROVII (Yarrow's Spiny Lizard). USA: NEW MEXICO: Grant Co.: 2.3 km S of Pinos Altos, 17 Sanctuary Road (32.84231ºN, 108.22386ºW, datum WGS84). 03 August 2008. Shawn White. Verified by J. Lee. Western New Mexico University, Gila Natural History Collection (WNMU 14782, small adult female, 57 mm SVL). Second county record. Increases the range by ca. 37 km. An additional large adult male (90 mm SVL) was found nearby in a boulder pile in a wooded lot and one juvenile (41 mm SVL) was found inside a residential structure. Both locations within Grant Co. are widely separated and at different elevations. This indicates the spread of a lizard into suitable habitat which it could not historically invade because of inhospitable terrain. Grant County has numerous mountain ranges interspersed with lower elevation plateaus which create the so called "sky islands." We believe the second record represents expansion by human efforts

beyond the historical range and therefore has value in documenting this type of movement. This species has been recorded numerous times in neighboring Hidalgo Co.

Submitted by **SHAWN R. WHITE** (e-mail: whites7@wnmu.edu) and **RANDY D. JENNINGS**, Western New Mexico University, P.O. SQUAMATA – SNAKES

CARPHOPHIS AMOENUS (Eastern Wormsnake). USA: INDIANA: Pike Co.: Patoka River National Wildlife Refuge and Management Area (38.34910ºN, 87.12384ºW; NAD 83, Zone 16). 10 April 2009. Michael J. Lodato and Alisha Maves. Verified by Chris Phillips. Illinois Natural History Survey (INHS 2009l). First county record (Minton 2001. Amphibians and Reptiles of Indiana, 2nd ed., revised. Indiana Academy of Science. vii + 404 pp.). Juvenile was found beneath a coverboard, adjacent to a cliff.

Submitted by **LINDSEY LANDOWSKI** (e-mail: Lindsey_Landowski@fws.gov), **MICHAEL J. LODATO**, and **ALISHA MAVES**. US Fish and Wildlife Service, Patoka River National Wildlife Refuge, 510 1/2 West Morton Street, P.O. BOX 217, Oakland City, Indiana 47660, USA.

COLUBER CONSTRICTOR (North American Racer). USA: NEBRASKA: Dawson Co.: Hiles Canyon, 10.2 km S Gothenburg (40.835333°N, 100.16305°W; NAD 83). 13 June 2009. Keith Geluso and Owen J. Johnson. Verified by Curtis J. Schmidt. Sternberg Museum of Natural History (MHP 14676). First county record. Fills gap in distribution in central Nebraska (Lynch 1985. Trans. Nebraska Acad. Sci. 13:33–57). Known from adjacent Lincoln Co. to the west and Frontier Co. to the southwest (Lynch 1985, *op. cit.*).

Submitted by **KEITH GELUSO** (e-mail: gelusok1@unk.edu) and **OWEN J. JOHNSON**, Department of Biology, University of Nebraska—Kearney, Kearney, Nebraska 68849, USA.

DIADOPHIS PUNCTATUS ARNYI (Prairie Ring-necked Snake). USA: TEXAS: Schleicher Co.: Eldorado, 12.8 air mi NW of jct U.S. Hwys 277 and 190, along Schleicher County Road 426 (30.9410167ºN, 100.79505ºW; WGS 84; elev. 2486 ft.). 07 April 2006. M. S. Price and S. G. Price. Verified by Travis J. LaDuc (photographic voucher TNHC 73400). First county record and fills a distributional gap (Dixon 2000. Amphibians and Reptiles of Texas, 2nd ed. Texas A&M University Press, College Station, Texas. 421 pp.).

Submitted by **MICHAEL S. PRICE,** San Angelo Nature Center, 7409 Knickerbocker Road, San Angelo, Texas 76904, USA; e-mail: michael.price@sanangelotexas.us.

ECHINANTHERA AMOENA. BRAZIL: MINAS GERAIS: Municipality of Santa Rita de Ibitipoca: Parque Estadual do Ibitipoca (21.703659°S, 43.885971°W; datum: SAD 69; elev. 1450 m). 16 December 1987. R. N. Feio. Museu Nacional / Universidade Federal do Rio de Janeiro, Rio de Janeiro, RJ, Brazil (MNRJ 7706, 7707). RIO DE JANEIRO: Municipality of Cachoeiras de Macacu: Reserva Ecológica de Guapiaçu (22.392222°S, 42.739444°W; datum: SAD 69; elev. 500 m). 14 January 2009. D. Vrcibradic. (MNRJ 18068). All verified by R. Fernandes. Species is known in southeastern Brazil, from southern Minas Gerais to southern Paraná, with one record in Minas Gerais, Municipality of Baependi and one record in Rio de Janeiro, Pedra Branca, Municipality of Parati (Di-Bernardo 1992. Comun. Mus. Cienc. PUCRS, sér. Zool. 5[13]:225–256). The record for the Parque Estadual do Ibitipoca is the northernmost for the species and the second for the state of Minas Gerais, ca. 105 km ENE from the closest previous record, Baependi. The record from the Reserva Ecológica de Guapiaçu is the easternmost for the species and the second for the state of Rio de Janeiro, ca. 220 km ENE from the closest previous record, Parati. Both localities are within the Atlantic Forest biome.

Texas A&M University Press, College Station, Texas. 421 pp.).

Submitted by **MICHAEL S. PRICE,** San Angelo Nature Center, 7409 Knickerbocker Road, San Angelo, Texas 76904, USA; e-mail: smichael.price@sanangelotexas.us.

LAMPROPELTIS TRIANGULUM ELAPSOIDES (Scarlet Kingsnake). USA: GEORGIA: Miller Co.: Mayhaw Wildlife Management Area, Griggs Lucille Road, 0.23 mi E Cypress Creek (31.197972°N, 84.792792°W; WGS 84). 03 March 2006. Collected by E. Adair, A. M. Durso, J. C. Maerz, K. A. Buhlmann, L. L. Smith, T. M. Luhring, A. M. Grosse, J. Norman, and the UGA Herpetology class. FLMNH 154594. New county record (Jensen et al. 2008. Amphibians and Reptiles of Georgia. University of Georgia Press, Athens. 575 pp.). An adult *L. t. elapsoides* was found under bark by the margin of a pond at ca. 1600 h. Extends the range 32 km SW from Baker Co., Georgia. Calhoun Co.: Chickasawhatchee Wildlife Management Area, unnamed road, 1.0 mi W Chickasawhatchee, (31.46611°N, 84.43340°W; WGS 84). 06 April 2008. Collected by K. T. Nelson, A. M. Durso, J. L. Devore, E. C. Susko, J. M. Pahlas, and R. C Joshi. FLMNH 154398. New county record (Jensen et al. 2008, *op. cit.*). An adult *L. t. elapsoides* was found under bark at the base of a snag at ca. 1100 h. This record is 45 km NE from Miller Co., Georgia (FLMNH 154594) and 20.4 km N of a 2007 record from Baker Co., Georgia. Both specimens verified by Kenneth L. Krysko.

These two records, together with the 2007 Baker Co. record (Stevenson et al. 2009. Herpetol. Rev. 40:247–249), represent the first reports of this species from the Dougherty Plain region of Georgia. The previous dearth of records may be due to limited sampling effort. The majority of non-agricultural land in the Dougherty Plain is under private ownership, creating accessibility issues for large-scale sampling. This may indicate that other species with poorly documented distributions within this region could be found in larger numbers with a concerted search.

Submitted by **ANDREW M. DURSO**, Eastern Illinois University, Department of Biological Sciences, Charleston, Illinois 61920 (e-mail: amdurso@gmail.com); and **KERRY T. NELSON**, University of Georgia, Warnell School of Forestry and Natural Resources, Athens, Georgia 30602, USA (e-mail: kerrytnelson@gmail.com).

LAMPROPELTIS TRIANGULUM MULTISTRIATA (Pale Milksnake). USA: NEBRASKA: Garden Co.: 100 m ESE Crescent Lake National Wildlife Refuge Headquarters (41.7605556ºN, 102.4355556ºW; WGS 84). 11 May 2007. Florida Museum of Natural History (UF 155187). Verified by K. L. Krysko. Third record for Garden County. Captured in pitfall trap by J. B. Iverson. ca. 14 km N of previous record (Converse and Baker 2000. Herpetol. Rev. 31:186). Previous records were from areas of rock outgroups, but new record is from sandhill country, at least 10 km (NW) from the nearest meager exposure of sandstone along an intermittent tributary of Blue Creek. This new specimen is also the first for the Crescent Lake Refuge despite field work at the site by Iverson over 29 years (ca. 46 field months, including 900–1100 m of drift fence with funnel traps and bucket traps run during most months), and 78 years of activity by Refuge personnel (including drift fences for snakes operated in 1939–1942 by Imler [1945. J. Wildl. Mgmt. 9:265–273]; and 7.4 km of drift fence run from 1987–94 [e.g., Smith and Iverson. 1993. J. Herpetol. 27:333–335]).

Submitted by **JOHN B. IVERSON,** Department of Biology, 801 National Road West, Earlham College, Richmond, Indiana 47374, USA; e-mail: johni@earlham.edu.

LAMPROPELTIS ZONATA (California Mountain Kingsnake). USA: CALIFORNIA: Alameda Co.: Camp Ohlone Regional Park, 8 km E of Calaveras Rd., 394 m elev. (37.49°N, 121.74°W; WGS84). 23 May 2009. Dino Labiste. Verified by Mitchell F. Mulks (University of California, Santa Cruz). MVZ Obs-Herp 1. New county record. Extends the range ca. 11 km N of the nearest documented record for the species (CAS 190487). At ca. 1200 h an adult male (78.8 cm total length, 110.5 g) was observed moving along an exposed, rocky streambed of a semipermanent creek. The surrounding east–west running valley is an extensively grazed, riparian mixed oak woodland, with sandstone outcrops dominating the southern-facing slopes, habitat more commonly associated with the *Lampropeltis getula* rather than *L. zonata (*Hubbs 2004. Mountain Kings: A Collective Natural History of California, Sonoran, Durango and Queretaro Mountain Kingsnakes. Tricolor Books, Tempe, Arizona. 324 pp.). Although in certain regions, the co-occurrence of these two species may not be uncommon (R. E. Staub, pers. comm.).

The occurrence of *L. zonata* throughout the Diablo Range is poorly documented, and little is known about populations occupying this region. There are undocumented observations of this species at Camp Ohlone and ~ 10 km NW near Arroyo del Valle Creek, Alameda Co. (M. F. Mulks, pers. comm.; Hubbs 2004, *op. cit.*). Museum specimens confirm that the species occurs at Mount Hamilton (CAS-SUR 1812, MVZ 229892), Alum Rock Park (CAS 190487), and from Henry Coe State Park (MVZ 229890–91). However, suitable habitat is present elsewhere in the Diablo Range and the lack of records may reflect a lack of sampling rather than a disjunct distribution as figured in currently published maps (Hubbs 2004, *op. cit.*; Stebbins 2003. A Field Guide to Western Reptiles and Amphibians, 3rd ed. Houghton Mifflin Harcourt, Boston, Massachusetts. 560 pp.).

This research was funded by a National Geographic Society/ Waitt Grant #W17-08 to Rulon W. Clark, San Diego State University. Scientific collecting permit (SC-9704) was issued by the California Department of Fish and Game.

TRICHEILOSTOMA ANTHRACINUM. ECUADOR: PROVINCIA DE ZAMORA CHINCHIPE: 6.5 km SE of Tundayme (ca. 3.58712°S, 78.43307°W; datum WGS84; elev. 1300–1500 m). April 2004. E. O. Carrillo and S. Aldás A. Colección de Reptiles, Museo de Zoología, Pontificia Universidad Católica del Ecuador (QCAZ 7396). Verified by O. Torres-Carvajal. Southernmost record for the species, extends its distribution ca. 220 km SE from the nearest locality (Balsapamba, Provincia de Bolívar, ca. 1.76667°S, 79.18333°W) in central Ecuador. Adult female found during the day by mining workers that were unearthing primary forest vegetation with bulldozers). This species is known from

only three localities on the eastern and western versants of central Ecuadorian Andes at 1000–1800 m elev. (Cisneros-Heredia 2008. Check List 4[2]:178–181). The present locality lies within a Low Montane Humid Shrub formation (Palacios et al. 1999. *In* Sierra [ed], Propuesta Preliminar de un Sistema de Clasificación de Vegetación para el Ecuador Continental, pp. 109–119. Proyecto INEFAN/GEF-BIRF and EcoCiencia, Quito) and is located on the western versant of the Cordillera del Cóndor mountain range.

Central American dry and pine-oak forests (Dinerstein et al. 1995; Olson et al. 2001) are among the most imperiled (Olson and Dinerstein 2002) yet understudied ecoregions (Sánchez-Azofeifa et al. 2005) within the Mesoamerican hotspot (Mittermeier et al. 2004; Myers et al. 2000). Less than 2% of the original dry forests and only 6% of pine-oak forests remain intact, with very little of either (< 5%) set aside in protected areas (Dinerstein et al. 1995; Janzen 1988). Accordingly, these forests formerly covered nearly all of southern Honduras, including the departments of Choluteca and Valle, but the persistent human need for subsistence agriculture, cattle production, and timber extraction has degraded or destroyed most of them, and many of the remaining patches are small and unprotected (AFE-DAPVS 2006; Carrillo and Vaughan 1994; Dinerstein et al. 1995; McCranie and Wilson 2002; Vreugdenhil et al. 2002). Despite this history of pervasive environmental degradation, the herpetofauna of the region has been reasonably well documented (McCranie 2007; McCranie and Wilson 2002; Sasa and Bolaños 2004; Wilson and McCranie 1998). Fifty-one species have been reported in this region, but like dry and pine-oak forests elsewhere in the country and across Central America, the herpetofauna has received little attention compared to that for other forest types. To remedy this deficiency, we sought to assess the herpetofaunal diversity of the only terrestrial protected areas in southern Honduras (AFE-DAPVS 2006). During 26 days in November 2005 and January and June 2006, we inventoried three Multiple Use Areas (MUAs) in the departments of Choluteca and Valle (Montaña La Botija, Cerro Guanacaure, and Isla del Tigre). Our surveys resulted in the documentation of 51 species of amphibians (15) and reptiles (36) (Lovich et al. 2006). We documented seven reptile species that were unknown from, but expected in the region (*Ameiva undulata*, *Lampropeltis triangulum*, *Ninia sebae*, *Oxybelis fulgidus*, *Scolecophis atrocinctus*, *Senticolis triaspis*, and *Spilotes pullatus*) and five others (two amphibians, three reptiles) that were unexpected (*Craugastor laevissimus*, *Ptychohyla hypomykter*, *Anolis cupreus*, *Hemidactylus frenatus*, and *Sceloporus malachiticus*), based on published accounts (IUCN, Conservation International, and NatureServe 2006; Köhler 2001, 2008; Köhler et al. 2006; McCranie 2007; McCranie and Wilson 2002; Villa 1972; Wilson and McCranie 1998) and unpublished field notes of Roy McDiarmid (pers. comm.). Two additional species (*Incilius coccifer* and *Oxybelis aeneus*), although known from the region, represent new records for Isla del Tigre, a volcanic island 1.9 km from the mainland, which contains the only protected dry forest in the Department of Valle. Museum acronyms follow Leviton et al. (1985). All vouchers were verified by J. R. McCranie unless otherwise noted. Locality coordinates were taken with a GPS device using map datum WGS84. If no English common name is available for a species, then the Spanish common names for amphibians are those found in McCranie and Castañeda (2007) and reptile common names are from one of the above listed publication sources in either Spanish or in English.

Anura – Frogs

Craugastor laevissimus (Ranita de Arroyo de Piel Lisa). CHOLUTECA: Quebrada La Fortuna, Cerro Guanacaure MUA, 15 km ESE Choluteca (13.259949ºN, 87.068716ºW), 350 m elev. 7 January and 4 June 2006. Mason Ryan and Walther Monge. Verified by Jay Savage. UNAH 5152, UNAH 5156, SDSNH 72860–72861. First records for the department of Choluteca, with the closest localities occurring in the departments of El Paraiso, Honduras (McCranie 2007) and Nueva Segovia, Nicaragua (Köhler 2001). One non-vouchered specimen from the same locality was sacrificed to test for the fungus, *Batrachochytrium dendrobatidis*, and the result was negative. All frogs were found among rocks and leaf

litter along a riparian habitat.

Incilius coccifer (Southern Roundgland Toad). VALLE: Isla del Tigre: La Laguna, ca. 1 km SSE Amapala (13.282400ºN, 87.654717ºW), 10 m elev. 14 June 2006. Robert Lovich. UNAH 5235. First record for Isla del Tigre, with the closest records occurring on the mainland in the departments of Valle and Choluteca (McCranie 2006), and in the neighboring departments of La Unión, El Salvador (Köhler et al. 2006) and Chinandega, Nicaragua (Köhler 2001, 2008). The frog was found at night along the shoreline of La Laguna.

Ptychohyla hypomykter (Rana Trepadora Común de Montaña). CHOLUTECA: Finca Jayacayan, Quebrada del Horno, Montaña La Botija MUA, 8 km SSW San Marcos de Colon (13.359615ºN, 86.832380°W), 1000 m elev. 9 January 2006. Mason Ryan. Verified by Jay Savage. UNAH 5155. First record for the department of Choluteca, with the closest recorded localities occurring in the neighboring departments of El Paraiso, Honduras (McCranie 2007), and Esteli, Nicaragua (Köhler 2001). The frog was found in riparian vegetation on a tree branch overhanging a stream.

Squamata – Lizards

Hemidactylus frenatus (Common House Gecko). CHOLUTECA: La Fortuna, Cerro Guanacaure MUA, 15 km ESE Choluteca (13.259949ºN, 87.068716ºW), 350 m elev. 3 January 2006. Thomas Akre, Robert Lovich, Antonio Robinson, Mason Ryan, and Norm Scott. SDSNH 72726; UNAH 5185–5186. First records for the department of Choluteca and confirm the presence of a population in Cerro Guanacaure MUA. While the species is reported as "widely introduced" on the Honduran mainland (McCranie et al. 2005, 2006), the nearest published records are from the department of Atlántida (Franklin 2000). Introduced to several locations in Central America (Köhler 2001, 2008), this species was first collected in Honduras in 1997, although its colonization since has been poorly documented (McCranie et al. 2006). The closest reported localities to our records are in the neighboring departments of La Libertad, El Salvador (Greenbaum 2002), and Chinandega, Nicaragua (Köhler 2001). All specimens were collected on buildings at night.

Sceloporus malachiticus (Lagartija Espinosa Verde). CHOLUTECA: Quebrada de la Florida, Montaña La Botija MUA, 11 km SSW of San Marcos de Colon (13.335833ºN, 86.840000ºW), 1263 m elev. 9 January 2006. Robert Lovich. SDSNH 72765. Quebrada del Horno, Montaña La Botija MUA, 8 km SSW San Marcos de Colon (13.359615ºN, 86.832380ºW), 1000 m elev. 9 June 2006. Thomas Akre. UNAH 5136. Las Moras, Montaña La Botija MUA, 9 km SSE San Marcos de Colon (13.356667ºN, 86.76000ºW), 1600 m elev. 10 January 2006. Walther Monge. UNAH 5125. First published records for the department of Choluteca (Köhler 2008, Wilson and McCranie 1998), with the closest known records being from the departments of Nueva Segovia, Nicaragua (Köhler 2001) and San Miguel, El Salvador (Köhler et al. 2006). The lizards were collected either on rock outcrops or logs exposed to sunlight in mixed deciduous forest.

Anolis cupreus (Anolí Común). CHOLUTECA: La Fortuna, Cerro Guanacaure MUA, 15 km ESE Choluteca (13.259949ºN, 87.068716ºW), 350 m elev. 3, 4, 6 January and 4, 6 June 2006. Sofia Nuñez. SDSNH 72729–72732, 72734, 72737–72739, 72741, 72743–72750, UNAH 5089–5091, 5093–5099, 5103–5110, 5111–5112. Cima de Cerro Guanacaure, Cerro Guanacaure MUA, 15 km SE Choluteca (13.243533ºN, 87.064450ºW), 950 m elev. 4 June 2006. Sofia Nuñez. SDSNH 72735. Tres Pilas, Montaña La Botija MUA, 5 km SE El Jocote (13.307568ºN, 86.766220ºW), 1160 m elev. 12 January 2006. Sofia Nuñez. SDSNH 72736; UNAH 5092). First published records for the department of Choluteca (Köhler 2001, 2008; Wilson and McCranie 1998), with the closest published localities being from the department of Chinandega, Nicaragua (Köhler 2001, 2008). Lizards were collected from shrub and tree branches in tropical deciduous forest no more than 2 m off the ground.

Ameiva undulata (Rainbow Ameiva). CHOLUTECA: La Fortuna, Cerro Guanacaure MUA, 15 km ESE Choluteca (13.259949ºN, 87.068716ºW), 350 m elev. 5 January and 6 June 2006. Sofia Nuñez. UNAH 5168, 5171, 5179, 5183, 5189; SDSNH 72692, 72697. Cima de Cerro Guanacaure, Cerro Guanacaure MUA, 15 km SE Choluteca (13.243533ºN, 87.064450ºW), 750–900 m elev. 4 January 2006. Sofia Nuñez. SDSNH 72693, 72696, SDSNH. Finca Guayabol, Cerro Guanacaure MUA, 16 km ESE Choluteca (13.253788ºN, 87.056948ºW), 590 m elev. 3 January 2006. Sofia Nuñez. UNAH 5180. La Isnaya, Montaña La Botija MUA, 0.5 km SSE Santa Rita (13.362283ºN, 86.732517ºW), 1140 m elev. 11 January and 11 June 2006. Robert Lovich. UNAH 5160, 5177; SDSNH 72695. La Pacaya, Montaña La Botija MUA, 5 km SW San Marcos de Colon (13.399552ºN, 86.834444ºW), 1000 m elev. 11 January 2006. Robert Lovich. SDSNH 72694. First published records for the department of Choluteca (Köhler 2001, 2008; Wilson and McCranie 1998). The closest known localities for this species are in neighboring departments of Chinandega, Nicaragua (Köhler 2001) and La Unión, El Salvador (Köhler et al. 2006). Specimens were collected among leaf litter and ground vegetation in disturbed tropical deciduous forest.

Squamata – Snakes

Lampropeltis triangulum (Milksnake). CHOLUTECA: Tres Piedras, Hwy 3, 7 km WNW of Nicaragua (13.086389ºN, 87.009444ºW), 70 m elev. 26 November 2005. Thomas Akre. LACM PC 1448. San Marcos de Colón (13.428889ºN, 86.804722ºW), 1000 m elev. 13 June 2006. Robert Lovich. UNAH 5044. First records for the department of Choluteca, with UNAH 5044 confirming the presence of the species in the newly declared Montaña La Botija MUA. Nearest published records are from the departments of Francisco Morazán, Honduras (Wilson and Meyer 1985), Jinotega and Matagalpa, Nicaragua (Köhler 2001), and San Miguel, El Salvador (Köhler et al. 2006). LACM PC 1448 was found on a road in disturbed tropical deciduous forest and UNAH 5044 was found in an urban setting.

Ninia sebae (Red-backed Coffee Snake). CHOLUTECA: Quebrada de la Florida, Montaña La Botija MUA, 11 km SSW San Marcos de Colon (13.337639ºN, 86.844611ºW), 1250 m elev. 9 January 2006. Thomas Akre and Norman Scott. SDSNH 72801; UNAH 5278. Las Moras, Montaña La Botija MUA, 9 km SSE San Marcos de Colon (13.356667ºN, 86.76000ºW), 1600 m elev. 10 June 2006. Sofia Nuñez. UNAH 5280. First records for the department of Choluteca, with the nearest published localities being from

the departments of Francisco Morazán and El Paraiso, Honduras (Wilson and Meyer 1985), Jinotega and Matagalpa, Nicaragua (Köhler 2001), and Morazán, El Salvador (Köhler et al. 2006). The specimens from Quebrada de la Florida were found under rocks in riparian habitats, whereas the Las Moras snake was beneath a rock near a cattle pond surrounded by disturbed cloud forest.

Oxybelis aeneus (Brown Vinesnake). VALLE: Playa Negra, 4 km S of Amapala, Isla del Tigre (13.251892ºN, 87.649656ºW), 25 m elev. 15 June 2006. Robert Lovich. UNAH 5267. First published record for Isla del Tigre, with the closest record known from nearby Isla Zacata Grande, Valle (Wilson and Meyer 1985). Nearest records in neighboring countries are from the departments of Chinandega, Nicaragua (Köhler 2001), and Morazán, El Salvador (Köhler et al. 2006). The snake was caught during the day on a roadside tree branch in disturbed dry forest vegetation, ca. 1.5 m above the ground.

Oxybelis fulgidus (Green Vinesnake). CHOLUTECA: Tres Pilas, Montaña La Botija MUA, 5 km SE El Jocote (13.307568°N, 86.766220°W), 1160 m elev. Norman Scott. UNAH5265. First record for the department of Choluteca, and highest elevation reported within its entire range (Köhler 2001, 2008). This species is known from nearby departments of Francisco Morazán, Honduras (Wilson and Meyer 1985), Chinandega, Nicaragua (Köhler 2001), and San Miguel, El Salvador (Köhler et al. 2006). The snake was caught during the day on a tree branch in a riparian habitat surrounded by pine-oak forest.

Scolecophis atrocinctus (Ringed Centipede Snake). CHOLUTECA: La Isnaya, Montaña La Botija MUA, 0.5 km SSE Santa Rita (13.362283°N, 86.732517°W), 1140 m elev. 7 October 2003. Charles Mayer. Verified by Kent Beaman. LACM PC 1455. First record for the department of Choluteca and increases the known elevational range by ca. 440 m (Köhler 2001, 2008). This species is also known from the nearby departments of Francisco Morazán, Honduras (Wilson and Meyer 1985), Esteli, Nicaragua (Köhler 2001), and San Salvador, El Salvador (Köhler et al. 2006). The snake was photographed along a trail in a pine-oak forest.

Senticolis triaspis (Green Ratsnake). CHOLUTECA: Las Moras, Montaña La Botija MUA, 9 km SSE San Marcos de Colon (13.356667°N, 86.76000°W), 1600 m elev. 5 February 2005. Charles Mayer. Verified Kent Beaman. LACM PC 1454. First record for the department of Choluteca and highest elevation reported for its range in Central America (Köhler 2001, 2008). This species is also known from nearby departments of Francisco Morazán, Honduras (Wilson and Meyer 1985), Esteli, Nicaragua (Köhler 2001), and San Salvador, El Salvador (Köhler et al. 2006). The snake was photographed along a trail in a remnant cloud forest.

Spilotes pullatus (Tropical Treesnake). CHOLUTECA: La Isnaya, Montaña La Botija MUA, 0.5 km SSE Santa Rita (13.362283°N, 86.732517°W), 1140 m elev. 11 January 2006. Charles Mayer. Verified Kent Beaman. UNAH 5275. First record for the department of Choluteca, with the closest localities found in neighboring departments of Francisco Morazán and Paraiso, Honduras (Wilson and Meyer 1985). The species is known from the departments of Matagalpa, Nicaragua (Köhler 2001) and San Miguel, El Salvador (Köhler et al. 2006). The snake was found on a tree branch ca. 2 m above the ground in mixed oak woodland.

Acknowledgments.—Funding was provided by Agency for International Development (USAID)/Manejo Integrado de Recursos Ambientales (MIRA). Permits were provided by Carla Cárcamo de Martínez of the Department de Areas Protegidas y Vida Silvestre (DAPVS), AFE-COHDEFOR, and Dahlia Merida of the United States Fish and Wildlife Service. Thanks to Edas Muñoz, Rafael Ochoa, Tim Wall, Antonio Corralez, Javier Tercero, Carlos Vicente Mendoza, and Charles and Hortencia Mayer for field and logistic assistance beyond all expectation. At Isla del Tigre we would like to thank the Honduran Navy and members of the installation for allowing us access onto Navy land.

Despite several extensive surveys and a wealth of historical records chronicling the distribution of reptiles and amphibians in Washington (for review see McAllister 1995), there are still large gaps in the documentation of species occurring within the southeastern portion of the state. This region comprises some 8800 km^2 and includes Asotin, Columbia, Franklin, Garfield, and Whitman counties. Most records for species reported to occur in this area are nearly half a century old, with several over 70 years old (Metter 1960; Svihla and Svihla 1933). Given concerns over the documented decline of many amphibian species around the globe (Alford and Richards 1999; Beebee and Griffiths 2005), a current knowledge of species' distributions is of utmost importance for the implementation of conservation strategies. Indeed, the need for further surveys reconfirming the presence of species in this area of Washington State is warranted, as recent surveys have revealed several novel county records (Dornburg and Weaver 2007a, 2007b; Weaver and Dornburg 2007).

In this note we report several first county records, in addition to noteworthy distribution records for reptile and amphibian species in southeastern Washington State. The records reported here were collected during 2005–2007 and verified by Kelly M. Cassidy at the Conner Museum, Washington State University (CMWSU). Coordinates listed use NAD83/WGS84 datum recorded with a hand-held Garmin® geographic positioning system (GPS) unit. The nomenclature used follows Crother et al. (2008). All specimens or photo vouchers were deposited within the Herpetology Collection, Department of Biological Sciences, Central Washington University, Ellensburg Washington.

Anura – Frogs

Anaryxus boreas (Western Toad). Garfield Co., Almota-Ferry Road (46.6708833ºN, 117.5054ºW). Two individuals (CWU 1685 and 1686) were observed on this road on14 May 2007. These are the first verified reports of this species for this county in 50 years.

Spea intermontana (Great Basin Spadefoot). Asotin Co., Peola Grade Road (46.3852167°N, 117.112483ºW). Four specimens were found along this road during a precipitation event on 02 May 2007. (CWU 1670–1674) These specimens represent the first verified records reported for this county in 34 years. Columbia Co., Tucannon River Road (46.4820167ºN; 117.9348333ºW). A total of four specimens were collected on 26 June 2005. (CWU 1677–1681). An additional specimen (CWU 1682) was collected on 10 June 2007 along this road (46.4579833º N,117.81495ºW). These represent first county records. Garfield Co., State Route 127 (46.61255ºN, 117.7904833ºW). A single individual was observed (CWU 1687) on 18 April 2007. This is the first verified report of this species from this county in 50 years. Whitman Co., State Route 127. (46.6699333ºN, 117.8033833ºW). Two individuals (CWU 1688) were observed on 17 April 2007. These are the first verified reports of this species for this county in 56 years

Squamata – Lizards

Plestiodon skiltonianus (Western Skink). Asotin Co., Asotin Creek (46.3148333ºN, 117.25335ºW). A single individual was observed under a rock on 10 September 2007. (CWU 1699). This is the first verified report of this species from this county in 69 years. Franklin Co., Palouse Falls State Park (46.6531333ºN, 118.2246ºW). An adult female and male (CWU 1683 and 1684) were observed under the same rock along the Palouse River within the state park on 07 June 2007. These represent first county records. Whitman Co., Snake River Canyon (46.6338167ºN, 117 15.001ºW). Three individuals (CWU 1688–1691) were observed on 01 May 2007. These are the first verified reports for this county in 54 years.

Sceloporus occidentalis (Western Fence Lizard). COLUMBIA CO., Tucannon River Hatchery (46.003 ºN, 117.711111ºW). Several individuals (one collected, CWU 1676) were observed basking on rocks along the river's edge on 27 July 2006. These are the first verified reports of this species from this county in 54 years.

Squamata – Snakes

Charina bottae (Northern Rubber Boa). ASOTIN CO., Asotin Creek Road (46.3290833ºN, 117.1006667ºW). A specimen was collected (CWU 1695) dead-on-road on 21 July 2008. This is the first verified report of this species from this county in 88 years. COLUMBIA CO., Tucannon River Road (46.3412 ºN, 117.682ºW). A single individual was observed alive-on-road (CWU 1675) on 16 October 2007. This is the first verified report of this species from this county in 77 years.

Hypsiglena chlorophaea (Desert Nightsnake). ASOTIN CO., Asotin Creek Road (46.3007167ºN, 117.265333ºW). An adult female was collected (CWU 1696) alive-on-road on 07 September 2007. Two additional specimens were collected (CWU 1697–1698) on 10 September 2007 along this same stretch of road. These represent first county records.

Acknowledgments.—We thank Kelly Cassidy for verification of these records. We thank David M. Darda for allowing us to deposit specimens and photo vouchers at Central Washington University. Specimens were collected by a Washington State Department of Fish and Wildlife scientific collecting permit issued to REW.

The extinction and decline of amphibians is either approaching or it has already reached a precipitous wall. Authors Collins and Crump deliver an informative and accessible resource about global amphibian declines in their recently published book *Extinction in Our Times: Global Amphibian Decline*. This book is well-organized, well-researched, and presented in a format that can be read by naturalists, students, and scientists who are interested in the recent history of amphibian declines. Understanding the cause and nature of declines while navigating through the science, government, and civil society is critically important to those who want to address this great challenge.

The foreward written by Thomas Lovejoy highlights the most important aspects of the book in a few brief pages. His message is that the response to amphibian declines requires more than a science-as-usual approach. Addressing and understanding amphibian declines requires scientific teamwork, organizational learning, community involvement, educational programs, and socio-political engagement on biodiversity issues. This book covers these topics within the context of scientific studies that identify causes of global amphibian declines.

The book starts with an overview and introduction to biodiversity, conservation biology and key issues of amphibian decline. Collins and Crump adopt Noss and Cooperriders's (1994) definition for biodiversity, which includes and considers the evolving interactions, relations, and processes shared among genes, individuals, populations, and species. Adaptations and the sustaining functions of ecosystem services are supplied from all levels biodiversity.

Collins and Crump do not make clear the distinction between species extinction and population declines. The distinction is necessary so that conservation perspective and priorities address issues of decline to scale (Luck et al. 2003). The authors write that they will focus on and consider only the species level because it is "…easier, faster and cheaper (p. 1)." This assessment runs counter to the analysis by Naidoo et al. (2008) suggesting that species

targets as the conservation priority do not conserve optimal levels of global ecosystem services. Green (1997), Hugues et al. (1997), Molnar et al. (2004), and Wood and Gross (2008) also focus on and discuss the importance of conserving population levels of demographics and diversity. Contrary to the authors' statement that they will focus on the species level, examples of population decline are well described throughout the book. Collins and Crump even suggest, "…we need to monitor as many populations as possible (p. 45)." Researchers should not be monitoring population declines only to determine what species are threatened, but because population diversity holds the largest reservoir of ecological energy and biomass. Population levels of biodiversity are the main supplier of global ecosystem services (Luck et al. 2003).

Collins and Crump note that climate change, disease and pollution have reached beyond 'protected' boundaries of national parks and other 'pristine' areas, which was "historically the best way to ensure a species' survival (p. 88)." The 'historical' approach as based on species centered conservation and continues to be used as many conservation biologists seek to contain as many endangered species into protected and networked areas as possible for the least amount of cost (Kareiva and Marvier 2003; Molnar et al. 2004). Orchard (1999) also cites one of the significant dangers with the species conservation approach preventing researchers' eligibility for funding unless species are red-listed in their jurisdiction. Conservation efforts must shift the focus, effort and fund research on population declines (Molnar et al. 2004). Local populations are more familiar and meaningful to people than abstract species binomials for animals living in a far off place. "A more profound way to encourage public appreciation for wetlands and for the animals that live in them is to familiarize people with ponds, marshes, and lakes (p. 34)." Although there are few amphibian species in Canada, for example, the abundance of amphibian populations provides many places where conservationists can educate and communicate about the extinction process in a direct way (e.g., Green 1997). While Collins and Crump steer toward a species level approach, their book is a valuable resource for educators and conservationists living in places where there are few amphibian species.

Chapter 2 covers the history of organizational and institutional responses to amphibian declines since 1989. The history is informative and interesting to read with large amounts of personal insight into scientific meetings, organizations and government initiatives aimed at putting amphibian conservation plans into action. The third chapter reviews case examples by describing the behind-the-scenes work of researchers and organizations working together to face difficult challenges as they unravel the mystery and communicate on the nature of amphibian declines. Through their combined history, Collins and Crump have intimate knowledge and lots of personal anecdotes that bring to light some of the more interesting yet unpublished aspects of the research and response into amphibian declines.

Subsequent chapters use accessible language in reviewing scientific details that unravel the mystery behind the major threats and declines in amphibian populations around the globe. They book includes some surprising statistics on the economics of introduced amphibian species, amphibian commerce in the pet-trade, and amphibians for food and lab specimens. The authors relate this information back to conservation management and declines. Although it is mentioned on p. 197 that the Global Amphibian Assessment (2008) identifies habitat loss and degradation as the greatest threats by far, the treatment of this topic by the authors is disproportionately small. There is a small section on land use change, but less discussion on the magnitude of declines caused by habitat fragmentation (e.g., Eigenbrod et al. 2008; Green 1997; Puky 2005). The conservation and management of populations poses significant challenges in context of roads, forestry, and urban development. The conservation topics chosen by Collins and Crump, in context of declines, include agricultural contaminants (although not others such as road de-icing contaminants), UV radiation, and emerging infectious disease. For each topic they explain how each issue relates to or is the cause of developmental abnormalities such as extra limbs or missing eyes.

Batrachochytrium dendrobatidis (Bd) causing chytridiomycosis (aka. the chytrid fungus) is discussed in every chapter. Chapter seven is devoted solely to this topic with an extensive review about the spread, epidemiology, biology, and effects of the Chytrid fungus. This story is both interesting and holds great importance in relation to the issue of amphibian declines because the disease has caused rapid and massive die offs in Central America and has spread to many other populations world wide (Lips et al. 2009). The authors highlight that chytridiomycosis has a unique and previously misunderstood relation to extinction; they call this the hyperdisease hypothesis (p. 200). Chytridiomycosis is indeed exceptional. With the single exception of the American chestnut blight no other infectious disease has been linked with or known to cause extinction.

Chapters 8 and 9 review the evolving and sometimes tense relationship between the scientist, the conservationist and the institutions they share. They explore the complex moral implications and challenges in decision-making among conservation biologists with respect to the spread of chytrid disease. Do we translocate wild animals to zoos and holding facilities when extinction is predicted via the path of a chytrid epidemic? Once the chytrid has spread it is likely to stay in the environment. This means that repatriation, difficult under 'normal' circumstances (Dodd and Siegel 1991), is unlikely to succeed. The authors address and review these and other challenges in context of the unique circumstances that the amphibian extinction crisis poses for conservation biologists. While the book raises some insightful points, clearer advice is needed for animal care committees, colleagues, scientific panels, government and granting agencies who may not weigh in appropriately on the morals, ethics, and priority in dealing with amphibian conservation research proposals. The authors mention a new field of 'ecological ethics' that is being established to address these problems (p. 188). This area of research is needed to put ecological consequences versus the individual rights of an animal into context. The debate surrounding the use of toe clips for mark-recapture studies (Funk et al. 2005) is recent example highlighting the importance of guidelines for ecological ethics.

The final chapter reviews the story of amphibian declines in context of what has been learned. The end of the chapter summary provides a list of questions in need of answers. In context of the types of questions being asked, Collins and Crump wonder if the 'canary in the coal mine' metaphor aptly describes the sensitivity of amphibians by noting that, "by the time amphibians respond, environmental quality has already deteriorated (p. 203)." The utility or truth to this metaphor is also questioned by Pechmann and

Wilbur (1994) who find no evidence to substantiate the proposal that amphibians are more susceptible to contaminants through their unique life history or because of their permeable eggs, skin, and gills.

In contrast to the arguments against the metaphor it may serve as a message to say that humanity must pay attention to amphibian declines as coal miners paid attention to a dying canary. A dead canary mobilized miners in much the same way that the ACAP has called for an unprecedented response to the declines (Gascon et al. 2007). In this framework, the metaphor is meaningful and serves a conservation utility. Metaphors can have different meanings and utilities (MacCormac 1985). Climatologists, for example, cite the canary in the coalmine metaphor in context of the rapid retreat of glaciers and climate change (Erdman 2009). With respect to amphibian declines, the metaphor delivers a message that we are in the midst of the sixth major extinction and amphibians are the predominant global extinction risk group (Wake and Vredenburg 2008). Amphibian declines are alerting us that there is a problem for life on earth. The loss of amphibians and their habitats threatens the steady supply of ecological services sustaining humanity, just as the mine atmosphere sustains a miner. Despite their contention with the metaphor, Collins and Crump do not loose sight of the message that "amphibians are a cautionary tale alerting us (p. 203)" or that "amphibians are a warning and a glimpse of possible future events (p. 203)".

An alternate hypothesis stemming from the canary in coalmine metaphor suggests that amphibians serve as better sentinels, indicators, or a bellwether of environmental degradation and contamination compared to other organisms in a local context. This is the interpretation that Collins and Crump disagree with as they cite research suggesting that some amphibian species are not as sensitive an environmental indicator as other species. Moreover, as the scientific narrative in this book demonstrates, monitoring declines, deformities and causal stress factors is tough work that requires robust analytical and proven field methods to distinguish natural from abnormal fluctuations. Hence, amphibians may not serve as good indicators for monitoring the immediate local response often required in environmental assessments (e.g., Pearce and Venier 2009). As global indicators, however, amphibian declines are alerting humanity about a modern ecological process that is cataclysmic in magnitude (p. 203).

Extinction in our Times: Global Amphibian Decline is a highly recommended read for herpetologists, students of herpetology, conservation biologists, non-profit organizations, nature enthusiasts, and citizens who want to learn about the nature and response to the crisis. The message in the book is relevant, clear, and includes 28 pages of references and 23 pages of footnotes. The hardcover is affordably priced at US $29.95 with good binding and effective black and white images capturing details of amphibians in crisis situations. While enjoyable to read, this book is also an important addition to the literature of amphibian declines that highlights the moral imperative and action that is needed to address extinction in our times.

e-mail: michel.laurin@upmc.fr

This book would have been better titled "The Rise of Limbed Vertebrates" because the taxa called "amphibians" in the book include genuine amphibians (the largest clade which includes lissamphibians but not amniotes), stem-tetrapods, and reptiliomorphs (amniotes included). It is abundantly illustrated, and the color plates are nice, but the illustrations are generally of low resolution and appear to have been treated as grayscale images, even though they are really line art. This results in an annoying diffusion dither pattern, especially visible around the scale bars and lettering of the figures.

The book is organized into fourteen chapters. The first chapter, on the history of earth and life, is nice and briefly covers topics from the Big Bang to the Cambrian explosion in biodiversity.

Chapter two, on "Advanced metazoans and the ancestry of vertebrates," which also covers the evolution of primitively aquatic vertebrates, is not as good. Some statements are not supported by recent works. For instance, it states (p. 29) that anaspids are "thought to be the ancestors of the modern lampreys," and that bone "is lost in the living jawless fish." Neither statement is supported by a phylogenetic analysis of early vertebrates (Janvier 1996a), which shows that hagfishes and lampreys are excluded from the smallest clade of vertebrates with a bony skeleton. Strangely, neither that paper, nor the most detailed, up-to-date review of early vertebrates (Janvier 1996b), are cited. The chondrichthyans are reported to be divided into two "categories," the sharks and the rays. Actually, the most fundamental division in chondrichthyans is between the holocephalans (chimaeras; not mentioned in the book) and the elasmobranchs, which include skates and rays (forming a clade), as well as "sharks," a paraphyletic group, since skates and rays are nested within it (this paraphyly is not mentioned in the book). The book also states that early osteichthyans had a paired swim bladder used to control buoyancy (p. 31), but the taxonomic distribution of the lung (a primarily respiratory structure) and of the swim bladder (primarily involved in buoyancy control) suggests that the lung is more primitive, since most sarcopterygians (dipnoans and tetrapods) and the basalmost actinopterygians (polypterids) have a lung, whereas the swim bladder is restricted to part of Actinopterygii (Laurin 2008a). Carroll's idiosyncratic view of phylogenetics peeks through in statements such as "These specializations of the feeding apparatus preclude lungfish from close affinities with terrestrial vertebrates." (p. 32), which will puzzle many readers. Similar statements are found in other chapters, about *Tiktaalik* (p. 44), *Ventastega* (p. 59) *Acherontiscus* (p. 107), *Ichthyostega* and *Acanthostega* (both on p. 151), amniotes and "lepospondyls" (p. 160), and some of them (e.g. for *Ventastega*) lead Carroll to suggest relationships that are not most parsimonious and are contradicted by the most recent phylogenies. Although Hennig (1966) clearly demonstrated that autapomorphies are phylogenetically uninformative (at least under parsimony) beyond demonstrating the monophyly of a taxon, Carroll states that autapomorphies can refute sister-group relationships (for instance, p. 212 on archegosaurids; pp. 262, 301 on aïstopods, adelogyrinids, and lysorophians), or that a taxon is sufficiently primitive to be a sister-group (p. 301, on "microsaurs"). Elsewhere (p. 160, ch. 5), Carroll uses widespread plesiomorphies to refute some relationships supported by synapomorphies (in this case, between "microsaurs" and lysorophians). Such statements presumably reflect Carroll's frequent confusion between sister-groups and ancestors, which surfaces in various sections of the book.

Chapter three provides a detailed description of the anatomy and evolution of the first limbed vertebrates and of their closest finned relatives. Some errors have crept in; for instance, figure 3.2 suggests that *Eusthenopteron* is more closely related to tetrapods than to *Panderichthys*, but this is contradicted both by the text and by conventional wisdom. The interpretation is sometimes naïve. For instance, the fact that *Tiktaalik* has been found in apparently freshwater deposits "indicates a major shift from marine to fresh water" (p. 41). In fact, sarcopterygians have frequently moved between both environments (Vermeij and Dudley 2000), and there is evidence of many marine limbed vertebrates (Laurin and Soler-Gijón 2006), including the barely more crownward Devonian *Tulerpeton* (Lebedev 1986), so this particular shift is unlikely to have been "major." This chapter includes a useful review of gene expression patterns in developing fin and limb buds, but it does not incorporate recent work on the basal actinopterygian *Polyodon*, which shows that many patterns previously considered unique to tetrapods are probably osteichthyan synapomorphies. Their loss in *Danio* is presumably an autapomorphy (possibly of a much larger group of teleosts) that may be associated with the loss of the metapterygial axis in teleost fins (Davis et al. 2007). There are also errors in the coverage of Devonian taxa. For instance, Carroll (p. 59) calls *Ventastega* an "unquestioned tetrapod," which is misleading given that digits are not preserved and that there is no guarantee that they were present (Laurin et al. 2000). The statement (p. 72) that "The retention of many primitive features of the skeleton confirms the position of *Ossinodus* near the base of tetrapods, and its divergence prior to the loss of the intertemporal bone and other derived features of *Ichthyostega* and *Acanthostega*" is contradicted by every phylogenetic analysis that has included *Ossinodus* (Warren and Turner 2004; Ruta and Coates 2007; Warren 2007).

Chapter four, on "the radiation of Carboniferous amphibians," includes detailed descriptions of early stegocephalians (limbed vertebrates) that constitute a strong point of the book. The taxa are presented in stratigraphic order, which does not always seem optimal, as when the earliest "microsaurs" are described on pages 107–117, and more recent ones on pages 128–130. Similarly, aïsto-

pods are described on pages 72, 97, and 130–141. The discussion of phylogenetic relationships is largely left to the next chapter, but many statements formulated in terms of ancestor-descendant relationships could have been replaced by statements of sister-group relationships (e.g., the statement on p. 141 that "No later amphibians are plausible descendants of this assemblage [aïstopods]").

The nomenclature is not formulated in phylogenetic terms either, or these terms have an idiosyncratic meaning. For instance, the statement (p. 91) that baphetids are "close to the base of the tetrapod stem" disregards the fact that this stem encompasses many finned sarcopterygians (all those that are closer to the limbed ones than to the dipnoans), such as *Eusthenopteron* and *Osteolepis*; Carroll actually means something like "along the tetrapod stem, close to the base of the clade of limbed vertebrates." Several statements suggest that Linnaean categories have an objective reality and that research can lead to "correct" rank assignments. One example (p. 141) mentions that for aïstopods, "as more has become known of these groups, it has become evident that there are no significant gaps allowing taxonomic distinction above the level of genera." Other examples can be found on pp. 91, 93, and 99. In fact, Linnaean categories are purely artificial and even undefined constructs required by rank-based nomenclature (Laurin 2008b).

More serious problems concern the lack of alternatives presented. For instance, the enigmatic *Westlothiana* is presented as a relative of amniotes (p. 102); there is no mention of the fact that the most comprehensive phylogenetic analyses suggest that it is either a stem-tetrapod (Laurin and Reisz 1999) or a basal "lepospondyl" (Ruta et al. 2003, Ruta and Coates 2007). Similarly, Carroll assumes that a tympanum was present in most temnospondyls, even those with a massive stapes such as *Balanerpeton* (p. 102) or *Dendrerpeton* (p. 117). The stapes of *Dendrerpeton* is even described as "reduced"(p. 262, ch. 10), but it is much more massive than its homologue in tetrapods with a tympanum (Laurin and Soler-Gijón 2006: fig. 7); and the presence of a tympanum in most temnospondyls is highly debatable (Laurin 1998a; Laurin and Soler-Gijón 2006).

Several functional interpretations are dubious. For instance, we read (p. 93) that the largely cartilaginous endoskeleton of *Crassigyrinus* "would have increased buoyancy in the water." Selective pressures to increase buoyancy are unlikely to have resulted in decreased ossification in an animal that presumably seldom came to the surface, and in which air in the lungs would instead created selective pressure to increase ossification to create a ballast, as we see in several aquatic tetrapods (Kriloff et al. 2008). The explanation is more likely to reside in the lower metabolic cost of producing and maintaining cartilage than bone.

Chapter five, on "adaptation, radiation, and relationships", opens with a long, unnecessary discussion of gaps in the fossil record that fails to consider that Hennig developed cladistics as a way of inferring phylogeny even with a scanty (or absent) fossil record. It also makes the usual mistake of considering that cladistics assumes evolution to be parsimonious (p. 146), rather than just representing a way to choose between alternative hypotheses; in that respect, parsimony in the most general sense is part of the scientific method itself.

The chapter then presents several stegocephalian phylogenies in figure 5.1, but lissamphibians were pruned from most of them. Only Carroll's (2007: fig. 77) phylogeny (reproduced in the book as figure 5.1D) includes lissamphibians. This is a poor choice, given that it shows temnospondyls (represented by "basal temnospondyls", Branchiosauridae and Amphibamidae) as the stem-group of a clade encompassing lissamphibians, "lepospondyls", and even amniotes. Even Carroll did not seem to accept this topology, since he presented another, less parsimonious, tree (Carroll 2007: fig. 78) in which temnospondyls form the stem of batrachians (anurans and urodeles) only. Fortunately, another figure (5.3) shows a stegocephalian phylogeny with lissamphibians, although Ruta et al. (2003) was used as the source, rather than the more recent tree derived from the expanded dataset of Ruta and Coates (2007). Even that tree was perhaps not the best choice, given that two recent doctoral theses (Pawley 2006, Germain 2008) contain reevaluations of its supporting matrix and have reached drastically different conclusions, with a monophyletic origin of lissampibians among "lepospondyls" rather than among temnospondyls (Marjanović and Laurin 2009).

Most of the text that discusses these phylogenies (pp. 146–147) is either plainly wrong or difficult to understand. For instance, we read (p. 147) that "A number of taxa at the base, including *Eusthenopteron* and other osteolepiform fish, *Acanthostega* and/or *Ichthyostega*, whatcheerids, *Crassigyrinus*, and baphetids appear as a series of separate lineages, without indication of the specific relationships between one another." This suggests a large basal polytomy, but that is not what the phylogenies show; instead, we simply have highly asymmetrical trees showing several sister-groups of crown-tetrapods. Even more misleading is the statement (p. 147) that "the cladograms of both Laurin and Reisz (1997) and Ruta et al. [2003] were concerned with the interrelationships of the modern amphibian orders, and yet were based on very few characters of these groups and so were unable to resolve their specific affinities with any of the Paleozoic taxa." In fact, both studies were based on numerous parsimony-informative characters (154 and 308, respectively), and both provided well-resolved and robust (though mutually incompatible) phylogenies showing a monophyletic origin of Lissamphibia either among "lepospondyls" (Laurin and Reisz 1997) or among temnospondyls (Ruta et al. 2003). Similarly misleading statements are made (p. 147) about the phylogenies presented by Clack (2002) and Ahlberg and Clack (1998). Chapter five is best ignored.

Chapter six on "the zenith of amphibian diversity" thoroughly describes the Permian diversity of stegocephalians. As elsewhere in the book, the interpretations do not always represent all plausible alternatives. For instance, it mentions (p. 163) "freshwater sharks" being associated with various stegocephalians. Probably this refers to xenacanthids, but Schultze and Soler-Gijón (2004) showed that at least some xenacanthids were able to live in saltwater. Similarly, we read (p. 185) that "Nearly all branchiosaurid species are represented by gilled larvae, but almost none are known from terrestrial adults. This implies that most were neotenic, spending their entire life in the water." Another equally plausible alternative is that the adults lived in another, more terrestrial, environment and were not preserved for that reason.

Chapter seven on amniotes does not present a phylogeny. The only amniote phylogeny is presented on page 3, and is an old-fashioned "bubble diagram" in which the width reflects the number of families. Such use of taxa of higher ranks as proxies of biodiversity has been strongly criticized because taxa of

a given rank fail to share any objective properties (Bertrand et al. 2006; Laurin 2008b). This amniote phylogeny contains more artificial – paraphyletic – groups than clades. The former include mammal-like reptiles (non-mammalian synapsids), reptiles other than archosauromorphs (apparently lepidosaurs, turtles, and various unspecified extinct taxa), and archosauromorphs (normally a clade, but here redelimited to exclude birds). In fact, paraphyletic taxa are enthusiastically used throughout the book.

Instead of a phylogeny, chapter seven presents a list of amniote characters sorted into autapomorphies, synapomorphies with other (unspecified) taxa, and primitive characters. The criteria for these polarizations are not given, although they appear to assume Carroll's preferred phylogeny. For instance, the absence of an intertemporal, of labyrinthine infolding, of palatal fangs, of lateral-line canal grooves, and of an otic notch, which are synapomorphies of crown-tetrapods under some phylogenies (e.g. Vallin and Laurin 2004; Pawley 2006: 386, 393–394), are thus interpreted as autapomorphies of Amniota, which is misleading. Carroll (p. 196) also suggests that "Of the Paleozoic tetrapods, only anthracosaurs are plausible sister-taxa of amniotes, but this affiliation may lie at the level of *Tulerpeton*, which indicates a very long ghost lineage…" In fact, this hypothesis has never been supported by a single published data matrix. Recent analyses (e.g. Ruta et al. 2003; Vallin and Laurin 2004) clearly show that diadectomorphs are the sister-group of amniotes, and that "lepospondyls" are the next sister-group of amniotes.

Carroll's scenario on the origin of the amniotic egg, originally proposed in 1970, is presented, but there is no mention that the only quantitative, statistical test of that hypothesis confirmed only one of its three predictions about body size evolution (Laurin 2004). Similarly, the possible taphonomic explanation for the small size of the earliest amniotes (preserved in tree trunks, which may have introduced a size filter) is not evoked.

Chapter eight on stereospondyls starts with an interesting review of extinction events, especially the end-Permian event. It also reviews recent phylogenies on this large clade of temnospondyls and scenarios about its origin.

Chapter nine on "The enigma of modern amphibian origins" is mostly phylogenetic and contains several misleading statements. For instance, Carroll (p. 229) states that herpetologists think that extant amphibians form the clade Lissamphibia, but that "Paleontologists… have suggested that they may have evolved from two or three separate groups of ancestral amphibians." This is a false dichotomy because many paleontologists consider lissamphibians to form a clade that excludes all known Paleozoic vertebrates. Carroll then erroneously states (p. 231) about the matrices presented by Laurin and Reisz (1997) and Ruta et al. (2003) that "none of the many unique derived features that distinguish each of the three groups of living amphibians from one another were included in these databases." Both matrices included such characters; for instance, characters 33 and 34 of the matrix of Laurin and Reisz (1997) are autapomorphies of Gymnophiona (maxilla palatal shelf and tentacular foramen). Carroll adds (p. 232) that "Even if it were true that frogs, salamanders, and caecilians had an immediate common ancestry from a single antecedent stock, there would still be many problems of determining how and when the key characters of the living orders had evolved and what was the nature of the immediate common ancestor. Neither of these questions is even considered in the analyses of Laurin and Reisz or Ruta and his colleagues." This is misleading because Laurin and Reisz (1997) focused on amniote origins, so lissamphibians were not extensively discussed, but a revised and expanded version of the matrix was presented by Laurin (1998a, b), and the two questions raised by Carroll were discussed there. Carroll states (p. 234) that "If the prior applications of PAUP have failed to resolve the specific patterns of interrelationships among the modern amphibian orders or to find their plausible ancestry among one or more Paleozoic lineages, what other means of analysis might be followed?" In fact, applications of PAUP have not failed; they have only failed to support Carroll's hypotheses.

Fortunately, chapter nine provides anatomical and functional data on lissamphibians (about breathing, prey capture, and locomotion, among others), which makes the non-phylogenetic parts of this chapter worth reading. These do not enable the reader to understand lissamphibian origins, but they are interesting in their own right.

Chapter ten reviews "The ancestry of frogs." It is framed in the age-old search for ancestors. Of course, the possibility that lissampibians are monophyletic is not evoked in that context. An extensive list of nested synapomorphies assumes that anurans (alone) originated among amphibamid temnospondyls. This is inconsistent with the hypothesis of urodele origins among branchiosaurid temnospondyls, which are nested among amphibamids (Fröbisch and Schoch 2009). But the descriptive parts of the chapter are useful.

Chapter eleven, on "The ancestry of salamanders," describes several Jurassic and Cretaceous urodeles. Carroll states that (p. 280) "In fact, it is the larvae that provide much of the data that enable us to trace the ancestry of salamanders into the Paleozoic." In light of this assertion, the simplistic interpretations of such data are surprising. For instance, Carroll opposes the "gradual" pattern of ossification in branchiosaurs with the "complete ossification of the skull at a very small size" in other stegocephalians and "as far back as *Eusthenopteron*." Yet, on the same page, he mentions that "In nearly all branchiosaurs that had been described previously, the smallest preserved specimens had already ossified nearly all the dermal bones of the skull." On the next page, he adds "At present, no branchiosaurids other than those of the genus *Apateon* clearly show the protracted sequence of ossification of the dermal skull." From all this, he concludes that "the capacity of branchiosaurs to ossify the dermal bones of the skull in a slow, sequential manner evolved only later, between the Westphalian D and near the end of the Carboniferous." Is it not much more likely that poorly ossified, weakly mineralized, tiny larvae have a low preservation potential and that they are thus generally not known? Hence, the absence of well-documented cranial ossification sequences in "lepospondyls" is almost certainly a taphonomic artifact. Developmental biologists usually consider that simultaneity in developmental events simply reflects lack of temporal resolution reflecting limitations in data, rather than true simultaneity (Bininda-Emonds et al. 2003: 341).

Chapters twelve covers "*Eocaecilia* and the origin of caecilians". For lack of space, the specific strengths and weaknesses of this chapter will not be discussed; they are similar to those of the other sections of the book. Chapter thirteen, "the success of modern amphibians", covers the fossil record of lissamphibians and their phylogeny. Chapter fourteen, "the future of amphibians," surveys

their fate in extinction events, especially in the current one cause by anthropic effects. These last two chapters are among the best in the book.

The bibliography is highly selective. For instance, Carroll cites Zhang et al. (2005), the first paper that provides molecular dating of the origin of Lissamphibia, Lee and Anderson (2006), a commentary, and other recent studies (San Mauro et al. 2005; Roelants et al. 2007). All these papers concluded an Early Carboniferous or Late Devonian origin of Lissamphibia, which is, as Carroll states (pp. 304–305), consistent with a polyphyletic origin of Lissamphibia. Yet, these ancient ages of Lissamphibia have been shown to reflect a suboptimal choice of dating constraints (Marjanović and Laurin 2007), and three dating techniques with very different assumptions point to a Permian origin (Marjanović and Laurin 2008), which is clearly incompatible with the polyphyly hypothesis. Molecular dating performed in another lab (Hugall et al. 2007: table 3) also concluded to a Late Carboniferous to Early Permian origin of Lissamphibia – even though no calibration points lay inside that clade, which is expected to lead to overestimation of all dates for nodes in it (Brochu 2004a, b; Marjanović and Laurin 2007), as Hugall et al. (2007:558) noted themselves. Omission of these papers from the bibliography will give readers the erroneous impression that molecular data unequivocally supports an Early Carboniferous origin of Lissamphibia and hence its polyphyly.

Similarly, Carroll cites Schoch and Carroll (2003), who concluded that developmental similarities between branchiosaurs and urodeles suggested an origin of the latter among the former, but he cites neither Schoch (2006), who showed that these similarities are primitive, nor Germain and Laurin (2009), who showed that these similarities are far fewer than initially proposed (although the second paper may have been published too late to be discussed in the book).

To sum up, this book contains much useful anatomical information, and is abundantly illustrated. It thus constitutes a valuable factual account of anatomical diversity of early stegocephalians. However, the large-scale phylogenetic interpretations, especially those concerning the origin of lissamphibians, are best ignored. The book also indulges in extensive story-telling which is, fortunately, not representative of modern paleontological thought. For more objective and rigorous assessments of early stegocephalian evolution and the origin of extant amphibians, the readers should consult some recent reviews (e.g. Anderson 2008; Coates et al. 2008; Marjanović and Laurin 2009).

I thank D. Marjanović for constructive comments on an earlier draft.

There are many books about snakes. Just a few examples: a decade ago, Greene (1997) published one, illustrated with stunning photos by the Fogdens; half a decade earlier, Seigel and Collins (1993) informed "herpetologists, biologists, and others" about snake ecology and behavior; and half a decade earlier yet, Seigel et al. (1987) focused on the ecology and evolution of snakes. Do we need yet another one?

Early in their Introduction, Mullin and Seigel point out that habitat loss, caused by the seemingly endless increase in the human population and coupled with escalating technological abilities and standards of living, is causing the declines of many organisms. A decade ago, Gibbons et al. (2000) pointed out that in the rush to focus on declining amphibians – certainly a real and pressing problem – the roughly equal declines in reptile populations are mostly being ignored. Although a number of the snake books that have appeared since then include a conservation component—the attractive contribution from Henderson and Powell (2007) has seven conservation-related papers, for example, and both previous "snake" books (Seigel et al. 1987; Seigel and Collins 1993) had a chapter on the subject—none have *focused* on this important topic. Of the eleven numbered chapters in the current volume, seven include the word "conservation" in their title and all at least touch on the topic. Each chapter also contains a short "future directions" section identifying areas requiring additional attention.

The first half of the book (Chapters 1–4, pages 5–148) is methodological in nature. Whole books have been written about the material covered in these chapters. The extensive coverage provides for an excellent starting place for anyone designing a new snake study, but for details, especially of complex software packages or procedures, one will probably need to proceed to more specialized literature once an approach is chosen. Many advances have occurred since research methods were reviewed by Fitch in the first "snake" book (Seigel et al. 1987), and Chapter 1 starts with those but quickly goes beyond them. There is more overlap with the recent contribution by Ferner (2007; strangely missing

from the reference section). Some of the newer or more complex methods covered here, such as occupancy modeling, are not covered by either previous publication, however. The second chapter is focused on using molecular techniques to infer the processes that determined current distribution. The authors cover sources of DNA, the methods for constructing trees, and—most important, and supported by several full-page illustrations—the biological significance of possible phylogenetic patterns. How phylogeography informs conservation decisions is also covered, although not in great detail; that task is taken over by Chapter 3, which focuses on population genetics. A long table—3.5 pages—detailing available microsatellite primers for snake species is likely to be a useful resource, though additional ones will doubtlessly be available before long. Tables listing studies and levels of intra-population (6 pages) and inter-population (3 pages) genetic variation will also be convenient references. The fourth chapter focuses on another new set of tools, habitat modeling. These have recently attracted much attention when they were carefully applied to predicting the potential final distribution of large constrictors that have invaded and are expanding their ranges and impacts in Florida (Rodda et al. 2008). The chapter touches not only on the models and their data requirements, but also on conservation applications. Unfortunately, it does not provide advice on how to respond to hysterical complaints from readers who do not like model outputs.

The second half of the text (Chapters 5–10, pages 149–280) offers reviews. The question of how behavioral data can be incorporated into conservation decisions is addressed in Chapter 5, which is arranged by study area (e.g., "invasive prey and predators"). Chapter 6 focuses on reproductive biology and its conservation implications—arguing that habitat protection, for a variety of reasons, simply isn't enough and an understanding of reproductive processes is essential for long term population viability. Captive rearing, and what to do with the individuals produced, are covered in Chapter 7, which provides a useful review of snake translocation projects—few of them successful, unfortunately. Chapter 8 addresses a complaint made by Dodd in the second "snake" book (Seigel and Collins 1993): that the efficacy of habitat manipulation tools such as creation of corridors has not been carefully assessed. A five-page table summarizing existing studies suggests very mixed impacts on snakes, and many other studies that do not provide conclusive results. Managers, who often rush to act without ensuring funding for long-term assessment of impacts, need to hear the authors' recommendation: "Until the safety and effectiveness of habitat manipulation is firmly established … [such] projects should be monitored experimentally." The authors of Chapter 9 take an unusual tack: instead of always being on the defensive, given the bad name snakes generally have in the general public and among managers, why not show that they are useful? In this case, they are suggesting snakes can act as indicators of environmental health—a term that is often poorly defined. They explore how snakes could be appropriate in monitoring for chemical contamination, for example, but point out that such use "by resource managers has been almost nonexistent." Chapter 10, which focuses on the widespread fear of snakes in many cultures, may both explain why this has been the case and suggest that it is not likely to change any time soon. The authors point out that familiarity breeds tolerance and focus on education as the only possible solution.

In the final chapter, the editors sum up where we are and consider where the future might lead. The chapter is divided into several sections, some of which summarize previous chapters and many that do not. Some of these are important for scientists with an interest in conservation to consider if they have not done so before. Two important examples: we need to acknowledge that some measure of uncertainty will remain no matter how much research we do, so we need to become better at learning when to feel secure enough to make recommendations for management; and we need to learn to better communicate these recommendations to managers. Among the priorities they identify for future work: add studies of processes, rather than individual species; examine the impacts of roads; better integrate molecular tools; and rely more on experimental, rather than correlational, inference. The summary is followed by over 60 pages of references, ranging from the 1500s to 2008, a five-page taxonomic index, and a shorter subject index.

This is not a book for the general public, but managers and scientists, both beginning and well-established, will find something of value. Upper-level undergraduate and graduate students may particularly benefit from this book as they begin to conduct their first research projects. Regardless, one topic we wished was covered is urban ecology. Conservation biologists have unfortunately long treated urban environments as worthless, something the extensive urban herpetology volume (Mitchell et al. 2008) shows to be untrue. Not only do urban settings offer the only growth industry in our field – as pointed out by the first line of the Introduction – but they also offer a great opportunity to educate a public increasingly disassociated from anything "natural." We feel this book may have also benefited from a chapter reviewing our current understanding of the natural histories of each major clade, and what conservation measures may be unique to these groups. The editors acknowledge the need for "research on a much broader array of snake taxa." Scolecophidians, for example, comprise around 10% of ophidian diversity yet are granted only three sentences in the entire book. These caveats aside, don't let the unassuming cover photo dissuade you from getting a copy of this book if you study or manage snakes—it belongs in your bookcase.

This is manuscript T-9-1177 of the College of Agricultural Sciences and Natural Resources, Texas Tech University.

Reptiles and Amphibians of the Southern Pine Woods, by Steven B. Reichling. 2008. University Press of Florida (www.upf.com). Softcover. xxi + 252 pp. US $29.95. ISBN 978-0-8130-3250-4.

JEFF BOUNDY

2000 Quail Drive, Baton Rouge, Louisiana 70808, USA
e-mail: jboundy@wlf.la.gov

"I trekked through this landscape in a perpetual state of anticipation." Thus, the author describes his first foray into the southern pine woods. These words aptly describe my own first experiences as well – anxious to see a unique herpetofauna previously known to me only from books. I had the unique opportunity to explore the pine woods herpetofauna as a salaried biologist with a perspective on management. I was repeatedly told that the woods needed to be managed. Ecologists, foresters, naturalists … all knew how the forests functioned and were sure of the keys to managing them: 'lightning-caused fires are vital,' 'fires by indigenous people had to supplement lightning,' 'a high stocking rate keeps a closed canopy, thereby preventing hardwood succession,' 'herbicide must replace fire,' 'prescribed burns in winter…or in summer;' one-by-one they offered clues, often conflicting, about pine woods management. Thus, when I opened Reichling's book, I looked first for a chapter on managing the southern pine woods. There was none.

Instead, the book begins with two introductory chapters and ends with an epilogue. The remaining 200 pages contain species accounts of amphibians and reptiles that characterize the Pine Woods herpetofauna. Reichling begins the Introduction with a wise disclaimer that assembling a catalogue of species that are defined by an ecotype is subjective. He then presents his criterion for how he selected each species: they are restricted primarily to what was, or remains of, woods dominated by four species of fire-resistant pines in the coastal plain from North Carolina to eastern Texas. Chapter One characterizes the Southern Pine Woods in terms of geography, stand structure, hydrology and other factors. The woods are subdivided into hydrologic series (flatwoods, ridge, savanna and rockland), and into areas of regional endemism (e.g., central Florida ridges, Apalachicola), each of which is further described in terms of the geographic and environmental factors that have produced and maintained each series. A section on pine plantations is included, and each of the categorized pine woods types is illustrated by a color photograph.

Chapter Two, "Observing amphibians and reptiles," begins with conflicting guidance. Reichling starts by encouraging the reader to seek out the pine woods herpetofauna, but follows with a plea that animals not be collected and a frightening paragraph on how destructive one's footfalls are to the fragile ecosystem of the litter layer—the basis for his next plea—to remain on established trails. The next paragraph describes the amount of hardcore, off-trail work needed to efficiently locate the pine woods herpetofauna: the logs to be rolled, the amount of ground to be covered, and the value of dumping tin sheets and cover boards about the landscape. The literal reader will be quite frustrated attempting to see a Pine Barrens Treefrog or Blue-tailed Mole Skink from the trail. "Locating suitable habitats" begins with a summary of state and federal sites that maintain natural pine stands, and follows with a summary of microhabitats and how some species of amphibians and reptiles use them. Absent from the list of state-owned pine lands are Louisiana's Wildlife Management Areas, including Sandy Hollow and Sicily Island Hills.

The species accounts are segregated into generalists, then flatwoods, savanna, ridge and rockland specialists, and finish with an "other" category of species not restricted to pine woods, but often found therein. Each species account begins with a topical essay—one that is pertinent to that species but also covers a broader concept such as cooperative agreements, land development, scientific discovery, field techniques, biogeography, captive management, invasive species, etc. A morphological description follows the introductory essay, always very detailed, including descriptions of larvae for amphibians. All but two of the 38 taxa are illustrated by a color photograph, and many are accompanied by specific habitat photographs as well.

Distribution Notes discusses the historic range, which is compared to recent records of occurrence. A map is associated with this section (except for the "other" species), which can be misleading if the reader has not read pages 6–7. The maps show existing pine woods enclaves currently inhabited by each species rather than the actual range of the species. Additional sections cover Habitat, Ecology and Natural History, and Conservation, and each account ends with a Summary. The habitat is described in terms of hydrologic series and dominant tree species, followed by microhabitat use by the animal. Aspects of natural history covered include feeding habits and reproduction, and there are frequent recurrences of microhabitat discussion.

For some taxa, Reichling discusses physiological adaptations and responses such as thermal preferences and dehydration rates. In these latter sections, he presents much information about the interactions of each species with their immediate environment. The essays are modestly referenced, and many of the details seem novel. At times, I wished I could put the book down, dash off to the local pine woods, and try some new search method suggested by Reichling.

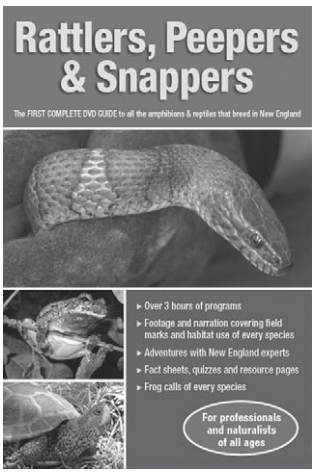
Discussions under "Conservation" are inconsistent between species: for *Plethodon kisatchie* only habitat preferences are reiterated; for *Pantherophis slowinskii* I gather that forest cutovers and trash dumps are positive conservation measures; for *Terrapene carolina major* we learn how to properly keep them as pets. For other species, conservation is discussed in terms of threats, typically direct human take, timber harvest practices or land development.

Remedies must be inferred.

The ten species considered in the "other" pine woods species category receive only a page or two that serve to introduce the species, then discuss some aspect of its biology; e.g., *Sceloporus undulatus* inhabits sites where it can bask; the defensive behavior of *Masticophis* is detailed; *Lampropeltis elapsoides* thermoregulates under pine bark. I agree with the author about the subjectivity of the species he has assembled, but I believe it would have been reasonable to have included *Rana capito* and *Plestiodon inexpectatus* in this section. Literature references are scattered within the species accounts, and approximately 180 citations are included in the Bibliography.

Despite the upbeat first paragraphs, the overall tone of the book is one of lamentation: the problem is loss of the pinelands, the culprits are industry and development. In the epilogue, Reichling's pessimism is unbridled, and any hope of saving the pinelands seems almost futile. He notes that local objectives such as protecting the Trans-Mississippi sandhills tend to be ignored, as global environmental issues have achieved top priority with the media and public. He offers few solutions, and these only on the last few pages. Here and elsewhere in the book Reichling offers provocative opinions on issues with which some readers may disagree. For example, he and I differ on the utility of Endangered Species listing, but I commend his view that conservationists should learn forest economics. Overall, Reichling has masterfully mingled his topics within the entirety of the book, and these are covered in various formats throughout the text. I finally discovered that pine woods management is covered extensively in the book—you just have to read the entire thing: forest dynamics on page 23, plantation silviculture on page 58, soil disturbance on page 160, prescribed burning on page 234, etc.

My wish list for this book, some directed at the publisher, includes better photographic reproduction and more anecdotes. Many of the 100 color photos are too dark (e.g., plates 1.19, 3.4, 6.14). The paucity of personal stories leaves me wondering how many of these species Reichling has found afield, and makes his personal affection for the pine woods seem a little distant. A few instances of strict adherence to the metric system are awkward: "approximately 324 ha;" "storm surge was 61–122 cm" (stick with 2–4 feet).



Reptiles and Amphibians of the Southern Pine Woods is less a textbook and more a story of the pinelands and their herpetofauna. After reading the book, I ventured into familiar pine woods with a revitalized spirit, with a modified perspective, as if a fresh set of eyes were pointing out things I had never realized, renewing in me the boundless enthusiasm that Reichling and I both experienced in our respective first trips to the pines.

Rattlers, Peepers, and Snappers, produced by Vince Franke, Science Advisor Jim Andrews. 2008. Peregrine Productions (www.peregrineproductions.com or www.rpsdvd.com). DVD. US $24.95.

GREGORY J. WATKINS-COLWELL
Yale Peabody Museum of Natural History, 170 Whitney Avenue, New Haven, Connecticut 06511, USA
e-mail: gregory.watkins-colwell@yale.edu

and
ALEX DORNBURG
Department of Ecology and Evolutionary Biology, Yale University, New Haven, Connecticut 06520, USA
e-mail: alex.dornburg@yale.edu

Rattlers, Peepers, and Snappers represents the first complete DVD field guide to all of New England's breeding reptiles and amphibians, focusing on the general ecology, life history, and conservation concerns of each of the region's 52 species. This is presented in two main sections, which may be viewed as a whole or as individual "adventures" (chapters) covering amphibians and reptiles respectively. The program includes narrations from ten researchers and conservation specialists working with various New England species in addition to over an hour and a half of extra features not in the primary film segments.

The primary amphibian segment has a run time of 38 minutes and is partitioned into six chapters. These draw on the research and experiences of Jim Andrews (The Vermont Reptile and Amphibian Atlas), Tom Tyning (Berkshire Community College), Aram Calhoun (University of Maine), Rebecca Chalmers (Vermont Department of Conservation), and Sean Blomquist (University of Maine). It opens with a discussion of amphibian spring migrations and introduces the common theme of the DVD: how the complex ecology and natural history of these organisms is often at odds with anthropogenic factors. The program next takes the viewer from the topic of spring migrations to the impact of road crossing mortality on amphibian populations, giving a first hand account of the challenges these organisms face when moving between habitats. Habitats are discussed in more detail in the next three sections that in turn cover species most often associated with vernal pools, streams, or bodies of permanent water. The program ends with a chapter on wood frog responses to various degrees of deforestation around vernal pool breeding sites featuring the research of Sean Blomquist, a Ph.D. candidate at the University of Maine.

The primary reptile segment runs for 49 minutes across nine chapters hosted by Jim Andrews, Liz Willey (University of Massachusetts), Tom Tyning, Chuck Smith (University of Connecticut), Dave Paulson (University of Massachusetts), Steve Parren

(Vermont Wildlife Division of Non-Game), and naturalist Alcott Smith. This program follows a similar theme of depicting the delicate balance of reptilian life history and ecological needs with their current and future conservation concerns. It opens with Jim Andrews guiding a field group through several continuous habitats to find multiple species of native snake and New England's only lizard species, the five-lined skink. The central themes are carried through the next sections on box turtle habitat use, the state of timber rattlesnake populations in New England, and cryptic suburban populations of wormsnakes. These sections are followed by a chapter focusing on habitat mitigation for racers in Vermont, demonstrating to the viewer that primary research can be incorporated into conservation use by non-wildlife state agencies. Chuck Smith's section on copperheads is next, followed by three sections covering fall migration, man-made turtle tunnels to prevent high levels of road mortality, and a concluding section on turtle nesting along the shores of the heavily developed Lake Champlain.

The DVD contains many additional features that enhance its educational value. Fact sheets for each species, including introduced species, highlight the conservation status of each of the species in the six individual New England states. These also contain an extra video discussing identification, natural history, and conservation concerns for each species. The video quizzes are designed for use in classroom settings and test the viewer's ability to visually identify several common species and frog calls. A chapter on taxonomy narrated by Jim Andrews explains that the taxonomy follows the Scientific and Standard English Names list published by SSAR (Crother 2008). Finally, a section entitled "what you can do," provides a downloadable pdf list of resources and suggested conservation projects that may give the viewer direction for further involvement.

Errors are minimal and include a typographical error on a quiz answer (e.g., Spadefott vs. Spadefoot), and editing errors such as video of an eastern gartersnake release during a section on ribbonsnakes. Additionally, the species list may be difficult to navigate if the viewer does not know the current common name, though the diversity of each species group is low making this a slight inconvenience at most. Overall these are very minor points and do not detract from the presentation of the material.

The section hosts give a human face and personality to each topic, allowing the viewer to witness wildlife professionals working with several northeastern species, many of which are declining. This is exemplified by the repeated appearance of Jim Andrews, whose presence provides not just visual continuity, but also a contagious, near-childlike enthusiasm for these animals that is coupled with an appreciation for the various habitats in which they reside. He manages to avoid alienating the viewers with subjects as potentially off putting as road kill (in which he stacks crispy snake and frog wafers he found while walking along a small stretch of road) or taxonomy where the presence of a Star Trek mug on the shelf behind his head further endears him to the viewers.

What may be the most complete DVD of amphibians and reptiles for any region in North America, *Rattlers, Peepers, and Snappers*, provides teachers, educators, and interested individuals with a resource from which to gain insights into the lives of these often misunderstood animals. Although most segments were filmed in Vermont, the overall messages apply to a broader stage and are most certainly applicable to the rest of the New England region if not larger sections of North America. The species fact sheets and included quizzes act as teaching aids and greatly enhance the potential value of the primary film segments for teachers and educators wanting a new way of engaging students' interests in local biodiversity. To conclude, the film segments are well thought out and clearly represent a labor of love. We highly recommend this DVD.

PUBLICATIONS RECEIVED

The Fruit, the Tree, and the Serpent, Why We See So Well, by Lynne A. Isbell. 2009. Harvard University Press (www.hup.harvard.edu). Hardcover. xi + 207 pp. US $45.00. ISBN 978-0-674-03301.

This intriguingly titled book outlines the author's 'Snake Detection Theory' which attributes a significant role to snakes as a driving force in the evolution of primates. Constricting snakes are argued to have evolved roughly concomitantly with primates and to have played a role in the increased role of vision over olfaction in these mammals and in the evolution of larger brain size. More specifically, catarrhine primates, including anthropoid apes, are part of a lineage that evolved along with venomous snakes and developed the most sophisticated visual system and the largest brains of any primates (versus, for example, the smaller-brained, more olfactory lemurs of venomous snake-free Madagascar). The author links changes in diet and sensory modalities to brain size and an enhanced 'fear module' that are key elements in the evolutionary arms race between primates and their ophidian predators. The underlying neurological bases of the theory are outlined, testable predictions are presented, and the relationship between the theory and human fears and mythology are explored in this extensively referenced book. The book is accessible to a general readership and, although focused on the mammalian perspective, will be of equal interest to herpetologists concerned with the evolution of snakes.

Sex, Size and Gender Roles, Evolutionary Studies of Sexual Size Dimorphism, edited by Daphne J. Fairbairn, Wolf U. Blanckenhorn, and Tamás Székely. 2007. Oxford University Press (www.oup.com). ix + 266 pp. Softcover. US $60.00. ISBN 978-0-19-954558-2 [also available in hardback edition].

The 20 chapters in this volume are derived from a workshop on sexual size dimorphism (SSD) held in Switzerland in 2005. The book is divided into three main sections exploring macro-patterns, micro-patterns, and mechanisms. Five of the chapters are herpetological in focus. In the macro-pattern part are chapters dealing with amphibians (by Alexander Kupfer) and reptiles (by Robert Cox,

Marguerite Butler, and Henry John-Alder) in general. The former chapter examines ontogenetic patterns in dimorphism, whereas the latter explores phylogenetic and geographic trends in SSD and considers the roles of selection and constraint in the patterns observed. Studies by Evgeny Roitberg on variation in dimorphism in the widespread Palearctic lizard *Lacerta gailis* and by Lukáš Kratochvíl and Daniel Frynta on SSD in eublepharid geckos are more fine-scaled analytical investigations. Finally, at the mechanistic level, John-Alder and Cox consider the role of testosterone in influencing SSD through growth rates. Other chapters deal with birds, mammals, insects, spiders, and even plants. The book as a whole includes an extensive list of approximately 1000 references and a glossary of nearly 100 terms. The contributed chapters represent a spectrum of approaches to the topic of SSD and the book should be of particular value to herpetologists with interests in behavioral and evolutionary ecology, as well as physiology and endocrinology.

My Life in Natural History: An Autobiograph, by Walter J. Breckenridge. 2009. Bell Museum of Natural History, 10 Church St. SE, Minneapolis, Minnesota 55455. V + 178 pp., 44 pp. pls. Softcover. US $29.95. ISBN 978-1-885209-59-7.

This is the autobiography of Minnesota's greatest naturalist, Walter Breckenridge, who died in 2003 at the age of 100. His notes for the autobiography were transcribed and organized by his daughter, Barbara Breckenridge Franklin, and have been published by the Bell Museum, with which he was affiliated starting in 1926. Breckenridge's detailed reminiscences paint a detailed portrait of both his personal and professional life. His 300+ publications (1929–1999) are enumerated in an appendix compiled by John Moriarty. Although most of his work was ornithological, Breckenridge's interests were varied and he published 34 papers on amphibians and reptiles and is known to most herpetologists for his 1944 book *Reptiles and Amphibians of Minnesota*, based on his Ph.D. dissertation — a pioneering work for the upper Midwest. The text provides some anecdotes about this research, as well as later work on toads and softshell turtles. Although known for his studies in Minnesota, Breckenridge traveled widely in the U.S. and Canada as well as the Neotropics. Beginning as a taxidermist at the Bell Museum he rose to become director. Aside from his academic and administrative activities, he also lectured widely to the general public across America and was a talented natural history artist. Forty-four color plates illustrate 67 of Breckenridge's paintings (most ornithological, but including two reptiles). This inexpensive book will be of special interest to herpetologists with an historical bent and those working or living in Minnesota, Breckenridge's native Iowa, or elsewhere in Midwest.

Erratum

In the September 2009 issue (vol. 40, no. 3, page 367), the range extension note for *Storeria dekayi texana* by Streicher used the term "longitudinal gap," when it should have appeared as "latitudinal gap."

Final Volume of the Series

BIOLOGY OF THE REPTILIA

Comprehensive Literature
of the Reptilia

Nearly 23,000 references with cross-referenced subject index in 1,400 pages (clothbound)

Pre-publication price to SSAR members: $95

For ordering information and full description, see *Herpetological Review,* September 2009, p. 258, or visit SSAR online: http://www.ssarbooks.com/

Cover Images for *Herpetological Review*

We are looking for photographic images to appear on future covers of *HR*. To be considered, preferred images should have the following qualities:

- Should be technically superior photographs (e.g., composition, lighting, etc., should be excellent; subject must be in focus).
- Should be taken in vertical format, or, if in landscape format, permit cropping to achieve a vertical orientation.
- Should be based on film or digital media; if the latter, the native resolution must be sufficiently high to permit cropping and/or enlargement to print publication quality (many "point-and-shoot" digital cameras do not produce image files with sufficient resolution for print publication).
- Preference will be given to images that depict poorly known species. These could include recently described taxa or species for which a color illustration has never been published.
- Preference will be given to images that communicate some aspect of the biology of the organism (e.g., predation, feeding, courtship, crypsis).

Images for consideration should be submitted as low-resolution jpg or pdf files. Do not send full resolution images via email. All submissions or questions should be directed to the Editor (herpreview@gmail.com).

Information for Contributors

Herpetological Review is a peer-reviewed quarterly that publishes, in English, articles and notes of a semi-technical or non-technical nature, as well as book reviews, institutional features, commentaries, regional and international herpetological society news, and letters from readers directed to the field of herpetology. Articles reporting the results of experimental research, descriptions of new taxa, or taxonomic revisions are not published in ***HR***, but should be submitted to the ***Journal of Herpetology*** (see inside front cover for Editor's address). To submit a manuscript to ***HR***, please consult the SSAR webpage at:

<http://www.ssarherps.org/pages/HRinfo.php>

Reprints and Page Proofs

Reprints of notes or articles published in ***HR*** may be ordered through EZReprints (EzReprint@odysseypress.com), an online reprint ordering system. Authors will receive email notification as the issue goes to press. Page proofs are sent electronically to authors of all articles, book reviews, and obituaries, but are not sent for natural history notes or geographic distribution notes. Proofs are sent as pdf files approximately 2–4 weeks prior to publication.

Advertising

Herpetological Review accepts commercial advertising. Rates and copy information are available from the SSAR web page (http://www.ssarherps.org/pages/HRinfo.php).

Herpetological Review (ISSN: 0018-084X) is published quarterly (March, June, September, and December) by the Society for the Study of Amphibians and Reptiles at Central Michigan University, Department of Biology, 217 Brooks Hall, Mt. Pleasant, MI 48859, USA. Periodicals postage paid at Mt. Pleasant, MI 48859 and at additional mailing offices. All rights reserved. No part of this periodical may be reproduced without written permission of the Editor, except that authors and their agents are permitted to reproduce and distribute their own articles and notes. **POSTMASTER:** Send address changes to Breck Bartholomew, SSAR Publications Secretary, P.O. Box 58517, Salt Lake City, UT 84158. **MISSING OR DAMAGED ISSUE?** Please notify Breck Bartholomew, SSAR Publications Secretary (e-mail: ssar@herplit.com) for a replacement.

SSAR Publications

SSAR publishes seven different series: *Journal of Herpetology, Herpetological Review, Facsimile Reprints in Herpetology, Contributions to Herpetology, Herpetological Circulars, Herpetological Conservation*, and the *Catalogue of American Amphibians and Reptiles* (see below for CAAR details). SSAR members receive pre-publication discounts on all *Facsimiles* and *Circulars* and on volumes in the *Contributions* and *Herpetological Conservation* series. A complete pricelist of Society publications is available at: http://www.ssarbooks.com/.

Catalogue of American Amphibians and Reptiles

The ***Catalogue*** consists of loose-leaf accounts of taxa prepared by specialists, including synonymy, definition, description, distribution map, and comprehensive list of literature for each taxon. Covers amphibians and reptiles of the entire Western Hemisphere. Available for purchase from the SSAR Bookstore (http://www.ssarbooks.com/). Use the prices below to order back issues.

COMPLETE SET: NUMBERS 1 – 840		US $460
INDEX TO ACCOUNTS 1 – 400: Cross-referenced, 64 pages		$6
INDEX TO ACCOUNTS 401 – 600: Cross-referenced, 32 pages		$6
SYSTEMATIC TABS (Ten tabs to fit binder: "Class Amphibia," "Order Caudata," etc.)		$6
IMPRINTED POST BINDER (Note: one binder holds about 200 accounts)		$35
INCOMPLETE SET: NUMBERS	1 – 190	$75
	191 – 410	$85
	411 – 840	$320

To order: make checks payable to "SSAR" and mail to Breck Bartholomew, SSAR Publications Secretary, P.O. Box 58517, Salt Lake City, Utah 84158, USA (fax 801/453-0489). e-mail: ssar@herplit.com. Online orders at: http://www.ssarbooks.com/.

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

www.ssarherps.org

The Society for the Study of Amphibians and Reptiles, the largest international herpetological society, is a not-for-profit organization established to advance research, conservation, and education concerning amphibians and reptiles. Founded in 1958, SSAR is widely recognized today as having the most diverse society-sponsored program of services and publications for herpetologists. Membership is open to anyone with an interest in herpetology—professionals and serious amateurs alike—who wish to join with us to advance the goals of the Society.

All members of the SSAR are entitled to vote by mail ballot for Society officers, which allows overseas members to participate in determining the Society's activities; also, many international members attend the annual meetings and serve on editorial boards and committees.

All members and institutions receive the Society's primary technical publication, the *Journal of Herpetology,* and its news-journal, *Herpetological Review*; both are published four times per year. Members also receive pre-publication discounts on other Society publications, which are advertised in *Herpetological Review*.

To join SSAR or to renew your membership, please visit the secure online Allen Press website via this link:

http://www.ssarherps.org/pages/membership.php

Future Annual Meetings

2010 — Providence, Rhode Island, 7–12 July (with ASIH, HL)
2011 — Minneapolis, Minnesota, dates TBA (with ASIH, HL)
2012 — Vancouver, British Columbia, dates TBA (with ASIH, HL, WCH)

About Our Cover: *Pseustes sulphureus*

Puffing Snakes or Birdsnakes, genus *Pseustes* (Wagler, 1824), comprise 2, 3, or 5 species depending upon the authority, and range collectively from Mexico through tropical America. The Giant Birdsnake, *Pseustes sulphureus*, with two subspecies, occurs on Trinidad, throughout the Amazon Basin, and in the Atlantic Coastal Plain of Brazil from the state of Ceará south to São Paulo. Reports of this species on Tobago are erroneous (Boos 2001. The Snakes of Trinidad and Tobago, Texas A & M Press). It is one of the largest New World colubrids (reaching at least 3,015 mm TL; Jorge da Silva 1993. Herpetological Natural History 1[1]:37–86). Although it lives in the understory and canopy of primary and transitional rainforests, the Giant Birdsnake also forages on the ground, where its prey includes nesting and hatchling tinamous, caprimulgids, nunbirds, eggs, and occasionally small mammals. When on the ground this snake and its congener *P. poecilonotus* often assume an odd position rigidly locked in an undulating pose.

A dramatic film on the internet features this species (misidentified as *Chironius fuscus*) raiding the nest of a Crimson-crested Woodpecker (*Campephilus melanoleucos*) while being attacked by the adults. Giant Birdsnakes, like many arboreal species, have a defensive display that is most effective when viewed laterally (Sajdak 2010 [*in press*], Hunters in the Trees: A Natural History of Arboreal Snakes. Kreiger Publ. Co.). The body is inflated from the eyes to about the level of the heart (Rossman and Williams 1966. Proc. Louisiana Acad. Sci. 29:150–156).

In the upper Amazon Basin, *P. sulphureus* is often observed in *várzea*, seasonally flooded forest. The margins (*restinga)* consist of alluvial soils supporting groundcover and a mixed canopy. The cover image, taken in this habitat, has an unusual history. An *Anolis transversalis* was being photographed 90 cm up a liana when the *Pseustes*, estimated at 3 m long, slowly wound its way down from the canopy. It advanced horizontally 2.3 m along the liana, pausing frequently. Upon reaching the camera the Birdsnake froze, practically touching the lens, and the exposure was made. Then it slowly retraced its path into the canopy. Such an encounter with any snake would be unusual, but the fact that this was an alert, visually oriented, diurnal species makes it unforgettable. The cover photograph was taken on the Shimbillo River, Loreto, Peru, by **William W. Lamar** using a Pentax LX 35mm SLR camera on tripod, a Pentax 20mm f/3.5 rectilinear lens set at the hyperfocal point and stopped down to f/22, with Fujichrome Velvia film pushed to ISO 100 at 8 seconds. Bill's experience in the Amazon and Orinoco Basins spans 35 years, and his efforts in northeastern Peru have produced nearly 400 species of amphibians and reptiles. Lamar is an Adjunct Professor of Biology at the University of Texas at Tyler. He is co-author with Jonathan A. Campbell of *The Venomous Reptiles of Latin America* and *The Venomous Reptiles of the Western Hemisphere*. He leads natural history tours for GreenTracks, Inc., **http://www.greentracks.com**. Recent travel has taken him to Chile, Amazonian Brazil and several islands in the tropical Pacific.

SSAR BUSINESS

Seibert Award Winners for 2009 Announced

The 18th annual Seibert Awards were presented at the 52nd Annual Meeting of the SSAR in Portland, Oregon, 22–27 July 2009. These awards are named in honor of Henri C. Seibert, an early and tireless supporter of SSAR (having served as an officer for over 20 years). In recognition of outstanding student presentations at the annual meeting, a single award was given in each of the following categories: Evolution/Systematics (9 presentations), Ecology (12 presentations), Physiology/Morphology (6 presentations) and Conservation (8 presentations). All awardees will receive a check for US $200 and a book from Chuck Crumly at University of California Press.

The Winners.—Systematics/Evolution: Jamie Oaks, University of Kansas, "Objective partition choice and the phylogenetic systematics and biogeography of the true crocodiles." Ecology: John Willson, Brian Todd, and Christopher Winne, University of Georgia, Savannah River Ecology Lab, Virginia Polytechnic Institute and State University, "Trap-happiness, temporary emigration and other factors affecting detectability and population estimation in aquatic snakes." Physiology/Morphology: Victoria Arch, T. Ulmar Grafe, Marcos Gridi-Papp, and Peter Narins, University of California Los Angeles, University Brunei Darussalam, "An Old World frog communicates in pure ultrasound." Conservation: Kristine Kaiser, Menemsha Alloush, Robin M. Jones, Susanne Marczak, Katherine S. Marineau, Mark V. Oliva, and Peter M. Narins, University of California Los Angeles, "When sounds collide: effects of anthropogenic noise on frog calling behavior."

Honorable Mention.—Ecology: Javan Bauder, Holly Akenson, and Charles Peterson, Idaho State University, University of Idaho, "Over the hills and far away: movements of prairie rattlesnakes across a mountainous landscape in a designated wilderness." Conservation: Anna Savage, Cornell University, "Experimental infection with *Batrachochytrium dendrobatidis* demonstrates genetic resistance to chytridiomycosis in *Lithobates yavapiensis*."

The judges were Laine Giovanetto (New Jersey City University), Todd Jackman (Villanova University), Eric Juterbock (The Ohio State University), Jacqueline Litzgus (Laurentian University), Laura Mahrt (Eastern Oregon University), Patrick Owen (University of Cincinnati), Benjamin Pierce (Southwestern University), Robert Reed (USGS), and Emily Taylor (California Polytechnic State University).

2009 Annual Meeting, Portland, Oregon

The Annual Meeting of SSAR took place from 22–27 July, 2009 at the Hilton Portland and Executive Tower, Portland, Oregon. In attendance were members of SSAR, American Elasmobranch Society (AES), American Society of Ichthyologists and Herpetologists (ASIH), The Herpetologists' League, Early Life History Section, Herpetological Conservation and Biology, Society for Northwestern Vertebrate Biology, and Society for the History and Bibliography of Herpetology. The meeting was hosted by USGS Forest and Rangeland Ecosystem Science Center, Portland State University, United States Forest Service, Washington Department of Fish and Wildlife, Washington State University, and Oregon State University.

The local hosts were R. Bruce Bury, Stan Hillman, Carl J. Ferraris, Jr., Deanna Olson, Marc P. Hayes, Peter Ritson, Robert Kaplan, David J. Germano, Tara Chestnut, Gwendolynn W. Bury, Douglas F. Markle, Jason Podrabsky, Brad Buckley, David L.G. Noakes, Brian Sidlauskas, Selina S. Heppell, Scott A. Heppell, and M. Rockwell Parker. The efforts of the local hosts, staff of the Kansas State University Division of Continuing Education, and many student volunteers resulted in another great JMIH.

There were 1170 herpetologists and ichthyologists from around the world at the 2009 JMIH. This number was up substantially compared with that in the previous year. Approximately 42% of attendees were students, and around 700 papers and 300 posters were presented. Eleven symposia, including the very well-attended "Darwin at 200: A View from Ichthyology and Herpetology," and three student workshops were scheduled. One of these workshops ("How to Get a Job after Graduation: Advice from Experts," see below) was organized by Dawn Wilson and other members of the SSAR Graduate Student Participation Society. The Henri Seibert Competition attracted 37 students in four categories this year (a greater than 50% increase over numbers in 2008). Most participants were in the Ecology category.

The Annual Meeting began officially at 0830 h on Thursday, 23 July with a welcome from R. Bruce Bury. Bruce provided a history of Oregon and Oregonians and a quick tutorial on ordering local beers (an apparently very complicated process). This was necessary as, to the delight of some of our members, the JMIH coincided with the 22nd Annual Oregon Brewer's Festival, one of the nation's longest-running craft beer festivals.

Hartwell Welsh, from the US Forest Service, spoke on the NW herpetofauna and threats to its persistence, including disease, manipulation of water flow, introduced predators, forestry practices, and contaminants. Douglas Markle and David Noakes (Oregon State Univ. and Oregon Dept. of Fish) gave a presentation on the diversity of freshwater fish in Oregon. Particularly interesting were the presumed effects of colossal floods and spectacular volcanic activity. President of ASIH, John Lundberg, then introduced a number of individuals who presented awards. Rick Winterbottom presented the Gibbs Award to Leonard Compagno, Brian Crother presented Jay Savage with the Johnson Award for excellence in service, and Mo Donnelly presented Bruce Bury with the Fitch Award for long-term excellence in the study of amphibians and reptiles.

The ASIH Past-President's Address was given jointly by Henry Mushinsky and his long-time collaborator Earl McCoy. They spoke on "Science, Advocacy, and Race to Extinction: The Tortoise and the Skink." Julian Lee was introduced by David Cundall as the 2009 Herpetologists' League's Distinguished Herpetologist. Julian gave a presentation entitled "From Bloomington, Indiana to Balankanche, Yucatan: Reflections of a Naturalist in Tropical America." He asked the excellent question "why would anyone wish to be anything other than a herpetologist (or maybe an ichthyologist)" and then proceeded to trace his own interest in herpetology beginning with a 1954 article in *National Geographic* magazine "Our Snake Friends and Foes."

Kenneth Goldman was the AES plenary speaker ("AES Fit *Agentea*") and the plenary session was closed by Bruce Bury.

Social and Professional Events

Mo Donnelly (Florida International University) kicked off SSAR's participation in the 2009 JMIH with the President's Travelogue on the evening of 22 July. Despite competing with a social in the hotel lobby, all seats were occupied as Mo spoke about "How Herps Helped Me See the World: A Travelogue (Fig. 1). Who knew Mo was almost a dental hygenist? She acknowledged the many people who have influenced her career, including Bayard Brattstrom, Lon McClanahan, and Jay Savage, and spoke about her work at La Selva (Costa Rica) and throughout much of South America. Great slides, great story—exactly what a President's Travelogue should be!

On the evening of 23 July, SSAR combined with HL to host another very successful reception for student members of both societies and invited

FIG. 1. Mo Donnelly presented the President's Travelogue. (Photo M. Preest)

professionals. This was intended as an opportunity for the students to meet professionals in their field, to make useful contacts, and to encourage their participation and contributions. Thanks to those who generously donated door prizes (Fig. 2). The Joint Meeting Reception was held immediately after the Student Reception at Oaks Park and doubled as the Picnic this year. Barbeque was enjoyed by most, and carnival rides by some!

The Student Participation Committee held a student workshop "How to Get a Job after Graduation" and Pizza Lunch on 24 July. The workshop involved a panel of professional herpetologists in a variety of positions (large research institutions, small colleges, regional universities, zoological parks, research stations, museums, and governmental agencies) speaking

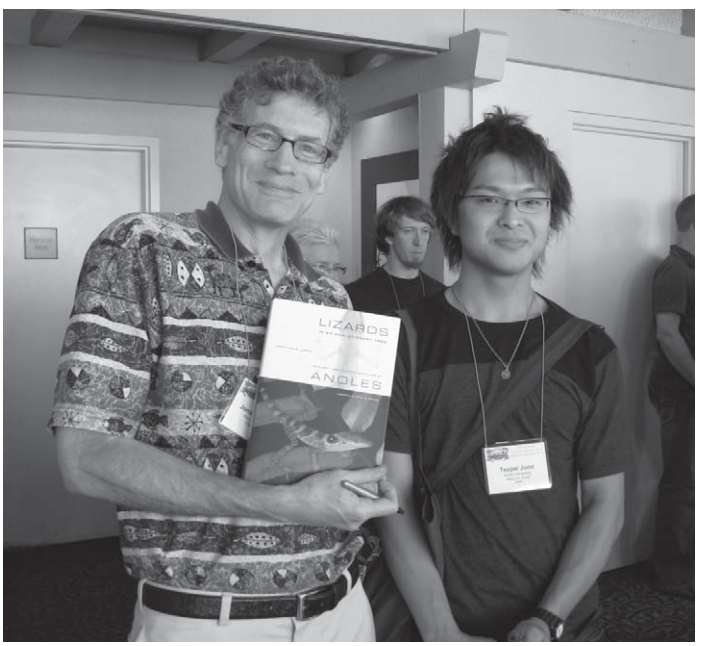

FIG. 2. Teppei Juno with Jonathan Losos, author of "Lizards in an Evolutionary Tree: Ecology and Adaptive Radiation of Anoles." A signed copy of Jonathan's book was the door prize won by Teppei at the Student Reception. (Photo M. Preest)

FIG. 3 Angela Marion, a very happy new owner of the "Leapin' Lizards" puzzle at the SSAR/HL Auction. (Photo M. Preest)

about their experiences getting jobs and serving on search committees and responding to questions from the students. The students completed a survey before they left the workshop. Their view of the workshop was uniformly favorable and they suggested some useful ideas for improvement and topics for future workshops.

The SSAR/HL Live Auction occurred on 26 July and raised $4048 to support graduate student travel (Fig. 3). Steve Werman and Robert Fisher were the auctioneers and were assisted ably by Stu Nielson, Perry (JR) Wood, Ed Stanley, Samantha Wisniewski, Ben Jellen, Lauren Adderly, and especially Greg Watkins-Colwell. Stan Hillman served as onsite coordinator before the meeting began.

Matt Venesky and Cari Hickerson (co-Chairs, Student Travel Award Committee) worked especially hard to pull together a successful Silent Auction ($612 raised). Matt and Cari have ideas to improve the visibility of this event for the 2010 meeting.

The Joint Meeting Banquet was held on the last evening of the meeting, and Larry Allen served as Master of Ceremonies. SSAR was represented at the head table by Joe Mendelson, III (President-Elect), Kirsten Nicholson (Treasurer), and Marion Preest (Secretary). At the end of the Banquet, a warm invitation was issued to attend the 2010 Joint Meeting of Ichthyologists and Herpetologists in Providence, Rhode Island, 7–12 July.

Board Meeting and Business Meeting Summaries

Society President Brian Crother called the Board Meeting to order at 0802 h on 22 July 2009 in the Hilton Portland and Executive Tower, Portland, Oregon. In attendance were 11 members of the Board of Directors and 17 Editors, Committee Chairs, or members of the Society (Fig. 4). Apologies were received from Roy McDiarmid, Kraig Adler, Andy Price, John Moriarty, Robert Hansen, Al Savitzky, and Ann Paterson. Minutes of the 2008 Board of Directors Meeting (Montréal, Canada) were approved.

Annual reports for 2008/2009 were submitted by all Officers, Editors, and Committee Chairs. President Brian Crother reported several personnel changes. Dawn Wilson stepped down as chair of the Student Travel Awards Committee, and Matt Venesky and Cari Hickerson (both student members) were appointed as co-Chairs. Kirsten Nicholson was replaced by Greg Watkins-Colwell as chair of the Nominations Committee and Lisa Hazard was added as a member of this Committee. Henry Mushinsky stepped down as organizer of the SSAR/HL Live Auction after many years and was replaced by Greg Watkins-Colwell. Stu Nielsen (another student member) replaced Richard Wassersug as Resolutions Chair.

Brian wrote over 70 letters of thanks to people who have provided

FIG. 4. Members of the Board and the Society at the Board Meeting. (L to R) Dawn Wilson, Travis LaDuc, Dick Durtsche, Stephen Richter, Robin Andrews, Kevin de Queiroz, Matt Parris, Betsie Rothermel, Charles Linkem. (Photo M. Preest)

service to SSAR in the past year, as well as letters of congratulations to winners of various SSAR student awards. He was involved (along with a number of other members of SSAR—particularly Joe Mendelson, III) in writing a short contribution to *Herpetological Review* and *Science and Children* that was a response to an article about using amphibians in the classroom and advocated the release of amphibians into the wild. A copy of this response is available on the SSAR website.

Journal of Herpetology received a prestigious award recently. It was recognized as one of the 100 most influential journals in the past 100 yrs in the Vertebrate Biology (Reptiles and Amphibians) Category by the Special Libraries Association (SLA; Fig. 5). This is a tribute to the many editors, editorial board members, and reviewers for this journal, and of course to the authors who send us their quality research. It is also a tribute to the officers and boards of directors over the years that have provided moral and financial support. Brian asked Past-President Roy McDiarmid and Board Member Kevin de Queiroz to attend a celebratory luncheon in Washington, DC on 16 June 2009 to accept the award on behalf of the Society. This award is announced on the website and a piece was published

FIG. 5. A toast at the end of the Board Meeting to the *Journal of Herpetology* for the Award it received from the Special Libraries Association. (Photo M. Preest)

in the September 2009 issue of *Herpetological Review*. A suggestion was made that the SLA Top 100 Journals logo be printed on the front cover of the *Journal*.

Brian arranged for Mo Donnelly to present this year's President's Travelogue. Additionally, he served as SSAR representative on the Meeting Management and Planning Committee (MMPC) and was involved in discussions concerning the future of SSAR with Allen Marketing and Management (AM&M, who currently handle our membership duties). Modest mark-ups in the costs of reprints and PDFs were approved.

Past-President Roy McDiarmid was involved with continued discussion of SSAR's participation as a full partner in JMIH. He provided input on a survey sent to the membership about annual meetings and also helped with interpretation of the results of the survey.

Treasurer Kirsten Nicholson reported that, while fiscal year 2008 was challenging, the Society ultimately fared better than was projected at the last Board Meeting. The approved 2008 budget projected overspending by almost $70,000; however, actual overspending was less than $3,900. Nearly all forms of income were substantially higher than predicted, although a few budget line items came in significantly overbudget.

The Society's investments lost an average of 42% of market value ($671,450 to $383,743). However, the value of the portfolio is slowly creeping back up. Kirsten regularly reviews the portfolio contents in consultation with accountant John Psaltos. The market value of all restricted funds as of December 2008 was $180,253.

Reprints from the Roger Conant library are available for purchase on the web. Breck Bartholomew (Publications Secretary) is making progress deciding how to handle the books from this library.

Kirsten will work on preparing the paperwork needed to satisfy IRS auditing requirements. This material will be circulated to the Board for approval. (Note added later: John Psaltos informed Kirsten that, because of the financial size of the Society, we do not need to have the paperwork in place for the 2008 tax filing. This gives us time to discuss this issue further at the 2010 Board Meeting.)

In the past year, Secretary Marion Preest prepared Board and Business meeting agendas and minutes for officers, editors, and committee chairs. Additionally, she prepared a summary of the 2008 meeting for publication in *Herpetological Review* and prepared the Annual Report for this year's Board meeting. Ongoing duties include updating SSAR letterhead and material on the website, answering or forwarding numerous emails, and ensuring that reports from Committee chairs are submitted for publication. Marion was involved in the student activities planned for the Portland meeting, in Nominations Committee duties, and she assisted President-Elect Joe Mendelson, III with an effort to recruit new members from the zoological, aquarium, and botanical park communities. She has continued (with tremendous help from Travis LaDuc, Regional Societies Board Member) to work on compiling a list of regional, national, and international herpetological societies so that SSAR can acknowledge significant events (e.g., anniversaries) in our sister societies. Marion called for a vote from the Board on a statement from the National Center for Science Education regarding the teaching of evolution in Texas schools. This statement was supported unanimously by the Board.

Breck Bartholomew reported that total income from the Publications Office in 2008 was $27,300.

Andy Price (Editor, *Catalogue of American Amphibians and Reptiles*) reported that an issue of *CAAR* will be ready by the end of 2009. Because *CAAR* is being published on an "as ready" schedule and no longer annually, we will eliminate all memberships that include receipt of *CAAR*. The Secretary will contact members who should have received *CAAR* as part of their membership benefits. She will explain the situation and ensure that they receive the issues they are entitled to. When *CAAR* is published in the future, it will be advertised on the website and available for purchase (or possibly free).

Contributions to Herpetology Editor Kraig Adler reported that "*Tasks and Problems in Studying the Life of Reptiles in Zoos*," by Hans-Günter Petzold, was published May 2008. "*Biology of the Reptilia, Volumes 20–21 (Morphology),*" edited by Carl Gans, Abbot Gaunt, and Kraig Adler were published in December 2008. These are the final text volumes in this series (begun in 1969) and both are selling strongly. "*Biology of the Reptilia, Volume 22, Comprehensive Literature of the Reptilia*," by Ernest A. Liner, will be issued in winter, 2009–2010. "*A Guide to the Snakes of the Philippines*" (Rafe Brown, Alan Leviton, Maren Gaulke, and Arvin Diesmos), "*Field Guide to Amphibians and Reptiles of the West Indies*" (S. Blair Hedges), and "*Lizards of Southern Africa*" (edited by William R. Branch and Aaron Bauer) are planned beyond 2009.

Facsimile Reprints in Herpetology Editor Aaron Bauer reported that "*Life and Herpetological Contributions of August Friedrich Schweigger"* was published in October 2008. A paperback edition of this work was distributed *gratis* at the 6th World Congress of Herpetology. Printing costs were supported by a donation from Mr. Ronald Javitch. "*Gray's Catalogue of the Specimens of Amphibians and Reptiles in the Collection of the British Museum*" is planned for 2010. Aaron anticipates one publication every two years for the foreseeable future. There was some discussion of other ways that herpetologists can access the material being published as part of this series.

Herpetological Circular 39 ("*Reptile Dealers and their Price Lists*," by Murphy and McCloud) is planned for late Fall 2009. *Herpetological Circular* 37—Crother et al., *Scientific and Standard English Names of Amphibians and Reptiles of North America North of Mexico*, is already out of print. Editor John Moriarty requested funds to print anther 100–200 copies. This request was approved.

Joe Mitchell (co-Editor, *Herpetological Conservation*) reported that *Herp. Conservation, Vol. 3* (*Urban Herpetology*) is being very well received and has already turned a profit for SSAR. Robin Jung-Brown and Breck Bartholomew stepped down as co-editors; however, Joe will remain as editor for one or two more volumes. A possible topic for Volume 4 is "Herpetological Conservation in Agricultural Landscapes."

Herpetological Review continues to operate smoothly according to Editor Robert Hansen. There have been some personnel changes: Brent Thomas and Michael Jorgensen stepped down and were replaced by Margaret Gunzberger and Dan Portik, respectively; Chris Phillips stepped down in July after five years of service. The "Amphibian Chytridiomycosis Geographic Distribution Section" was introduced in 2007. It receives considerable manuscript submissions and has been given a broader focus and renamed "Amphibian Diseases." Manuscripts submitted to this section are fast-tracked for publication. Bob requested continued consideration of publishing an online version of *Herpetological Review* and more extensive use of color.

Geoff Smith stepped down as *Journal of Herpetology* Editor in January 2009; however, he continues to process manuscripts submitted before 2009. Current Editor Matt Parris reported that submission rates were up slightly for 2008. The rejection rate continues at around 60% and there is a 9–12 month wait between acceptance and publication. This is expected to decrease given a 34% reduction in submissions in 2009.

Authors are now allowed to generate keywords and this will be useful for abstracting services, for those who use EndNote, etc. Matt and Geoff revised the "Guidelines for Authors" and the new version is available on the SSAR website.

Matt is exploring the option of converting to a trim size of 8.5 × 11 inches. He thinks this could facilitate modern mechanisms of document delivery, increase ease of PDF file transfer, stimulate increased interest in the journal, and would also help deal with the backlog of accepted papers. Matt will look into the budgetary implications of such a change.

Breck Bartholomew suggested that Matt consider using different photos/cover art on each issue of *Journal of Herpetology* as *Herpetological Review* does. Matt will remove the membership pricing information from the inside back cover. From now on, membership pricing will only be published on the website.

Betsie Rothermel (Chair, Conservation Committee) reported that Stephen Richter stepped down as co-chair. He was replaced by Joe Mendelson, III, who then stepped down when he was elected President-Elect in Oct.,

2009. Three new student members were added to the Committee—April Barreca, Jen Germano, and Andrea Dreyer. The Committee took action on a number of matters: a) they submitted a letter in support of the listing of the recently described Reticulated Flatwoods Salamander under the ESA as endangered, b) they supported the designation of critical habitat for the Reticulated Flatwoods and Frosted Flatwoods Salamanders, c) they submitted a letter opposing proposed changes to rules governing interagency consultation under Section 7 of the ESA (this would have removed the requirement for federal agencies to consult with USFWS or NMFS when determining impacts to threatened and endangered species), and d) they wrote a letter in support of the State of Florida's new regulations regarding the harvesting of freshwater turtles.

The Committee is considering whether it is better to submit joint letters or individual letters from the herpetological Societies. The answer probably depends upon to whom the letter is being addressed, e.g. in some cases number of letters received may carry more weight than who actually signed the letter. The Committee may conduct an online survey to identify members interested in receiving boiler plate letters from the Conservation Committee that they can then sign and submit to relevant agencies.

Chair of the Dean Metter Award Committee, Joe Beatty, received 24 proposals this year. All were of high quality and two winners were chosen. They are: Benjamin Jellen (St. Louis University) who is working on pre- and post-copulatory determinants of reproductive success in *Nerodia sipedon*, and Jeanine Refsnider (Iowa State University) who is attempting to determine if nest site selection can compensate for global climate change effects on sex determination in *Chrysemes picta*.

Erik Wild and Josh Kapfer (co-Chairs, Grants-in-Herpetology Committee) received 71 proposals in 2009. Applications were sent from 27 states in the US and eight countries (including the US). Most applications were received in the "Field Research" category. The winners each receive $500 and they are:

Conservation: Rosalinda Palomo-Ramos, New Mexico State Univ.

Field Research: Jeanine Refsnider, Iowa State Univ.

Laboratory Research: Brittany Barker, Univ. of New Mexico

Travel: Arley Camargo, Brigham Young Univ.

International: Carlos Miguel Del Valle-Useche, Universidad Nacional de Colombia

Education: Dan Costel, Lowry Park Zoo

Eric and Josh plan to work with webmaster Raul Diaz to introduce a more formalized process for receipt of grant applications.

The 17th annual Seibert Awards Competition was run at the 51st Annual Meeting of the SSAR in Montréal, Québec. There were 21 eligible presentations. The Seibert Award winners for 2008 were: **Systematics/Evolution**: Julienne Ng, University of Rochester, "Dewlap color and reproductive isolation in *Anolis distichus*." **Ecology**: Forrest Brem, University of Memphis, "Environmental transmission: a mechanism of disease-induced amphibian extinctions." **Conservation**: David Pike, (with co-authors Jonathan Webb and Richard Shine), University of Sydney, "Landscape-scale reptile conservation: experimentally manipulating canopy cover to restore a reptile assemblage." Honorable mentions were: **Ecology**: April Barreca (with co-author Jason T. Irwin), Central Washington University, "Seasonal habitat use and movement of Cascades frogs (*Rana cascadae*) in Washington." **Conservation**: Brian Todd (with co-authors Thomas Luhring, Betsie Rothermel, and Whit Gibbons), Savannah River Ecology Lab and Austin Peay State University, "Interspecific effects of upland forest clearing on amphibian migrations: implications for habitat and population connectivity." All winners received a check for US $200 and a book from University of California Press compliments of Chuck Crumly.

Two new members (Carlos Navas and Michael Dorcas) were added to the Herpetological Education Committee in the past year. Chair, Cathy Bevier reported that an updated webpage with information and resources for educators and students is accessible from the SSAR website. The committee invites submission of materials that promote teaching and learning about topics in herpetology. The Committee submitted a proposal for a Meritorious Teaching Award in Herpetology to be considered by the governing boards of SSAR, HL, and ASIH. The annual award would be presented to a nominated and qualified individual, and would include a plaque and cash prize ($500). The Board voted unanimously in support of providing this Award.

Lynnette Sievert (Chair, Kennedy Award Committee) announced that the winning paper for 2008 is by Erica Bree Rosenblum, "Preference for local mates in a recently diverged population of the lesser earless lizard (*Holbrookia maculata*) at White Sands" *Journal of Herpetology* 42:572–583." Erica will receive a check for $200 or $400 in SSAR publications.

The Meeting Management Planning Committee (MMPC) met in Portland in April to develop a meeting schedule and review conference facilities. SSAR representative on this committee, Brian Crother, noted that over 1000 presentations (papers and posters) will be made at the 2009 meeting. Future meetings are to be held as follows:

- Providence (2010)
- Minneapolis (2011)
- Vancouver (2012; with the WCH)
- Albuquerque (2013)

There was ongoing discussion of the current hotel-based meetings with professional organizers versus the former university-based meetings and the issues of cost, ease of planning, and workload placed on the local hosts. The Albuquerque meetings are being evaluated for either university or hotel meetings.

The MMPC developed a survey to poll the JMIH membership on the state of the meetings. 713 members of SSAR, HL, ASIH, and/or AES completed the survey and the results were sent to all members in mid-summer, 2009. Responses to some key questions are presented below:

Should SSAR and HL meet separately from ASIH and AES?
42% no, 35% neutral, 25% yes

Is meeting status quo acceptable?
70% yes

Where would you prefer to meet regardless of cost?
60% - University-setting

Should cost be the main factor in choosing between university and hotel?
77% yes

Are you satisfied with hotel rates?
57% no, 16% yes

Most respondents were satisfied with geographic locations, meeting duration, meeting space, program quality, and the information provided prior to the meeting.

Another meeting organizing company will bid against Kansas State for future meetings. The Board discussed the roles of the picnic and banquet at the meeting. The general consensus was that the picnic was more popular than the banquet. A suggestion was made that we hold a picnic/banquet hybrid earlier in the meeting. This may lower cost and increase attendance at this event. There was also discussion of the possibility of shortening the meeting by a day or two, the cost of housing, and the implications to the Society(s) financially responsible for the JMIH of not filling the room block.

Greg Watkins-Colwell replaced Kirsten Nicholson as chair of the Nominations Committee and Lisa Hazard was added as a new member. In 2008 the Nominations Committee generated a list of candidates for President-Elect, three regular Board Members, and one non-US Board member. Kirsten Nicholson and Marion Preest were willing to run again for the positions of Treasurer and Secretary respectively. The members of the Nominations Committee thank all Society members willing to run for these positions. There is no election being held in 2009, but the Committee welcomes suggestions for 2010.

Richard Wassersug presented resolutions at the SSAR Business Meeting in Montréal in 2008. Richard stepped down as Resolutions Chair and was replaced by Stu Nielsen.

The 6th Edition of the Scientific and Standard English names list was published one year ago and the web version is in development. Brian

Crother reported that the Committee is uncertain how updates will proceed (i.e., quarterly or as new information comes in). The 6th Edition has attracted attention because of certain name usage, claims of authoritarianism, and the review process. These claims are forthcoming as a Point of View paper in *Herpetologica*. The Committee has responded with two contra papers.

In Montréal, SSAR hosted a reception and a pizza lunch for student members of SSAR. A new committee, the Student Participation Committee (SPC; Dawn Wilson, Chair) was formed at the Board Meeting in 2008. Members of the SPC are professionals and students interested in furthering student involvement and student-centered activities in our Society.

Ten students were selected randomly from a pool of 23 applicants to receive travel awards ($400) for 2009. Matt Venesky and Cari Hickerson (co-Chairs, Student Travel Awards Committee) organized the 2009 Silent Auction to raise funds for this Award. There was discussion for next year of putting the materials in the Silent Auction in a high-traffic area to encourage bidding on items, e.g., where the Poster Sessions are held. A suggestion was offered that receipt of a travel award next year be made contingent on the awardees staffing the silent auction materials when they are on display. This suggestion received wide support among the members of the Board. A further suggestion was made to do away with the Silent Auction, and instead just hold the Live Auction (both auctions raise funds for Student Travel). This would have implications for the SSAR Travel Awards budget as the proceeds from the Silent Auction are for SSAR alone, whereas the proceeds from the Live Auction are shared with HL. The Board decided to let Matt and Cari try some new ideas to reinvigorate the Silent Auction next year and to continue to hold both auctions for the time being.

Anne Maglia (Chair, Web Oversight Committee) reported that, over the past year, the Web Oversight Committee focused on enhancing the utility and information content of the SSAR website as well as modifying page infrastructure and server support so that the forums are more secure. The website continues to be updated on a regular basis. The image gallery was converted and the photographs from the 50th Anniversary banquet are available for viewing and purchase. Suggestions for additional changes to the website are welcomed. Anne thanked Raul Diaz (webmaster) for his many volunteer hours and dedication to the Society.

For the first time, voting in the SSAR election was carried out electronically (although for those members without access to email, paper ballots were provided). Elections Officer, Dan Noble reported that this new procedure did not increase voting participation substantially.

The following SSAR members were elected:

President-Elect: Joe Mendelson, III

Treasurer: Kirsten Nicholson

Secretary: Marion Preest

Regular Board members: David Cundall, Kevin de Queiroz, Ann Paterson

Non-US Board member: Pat Gregory

All amendments to the By-laws were approved (minor changes were needed because of the switch to electronic voting and also because of a change in how we deal with members in arrears for payment of dues). The Board talked about how to increase voting participation, e.g., use Facebook to contact student members to increase communication and encourage voting, etc.

Al Savitzky attended the AIBS Council Meeting and Annual Meeting and part of BioOne Publishers and Partners Meeting in May, 2009. Reports were made on the first 14 months of progress on the Encyclopedia of Life and on the status of NSF funding for biological sciences, particularly organismal and environmental biology. Expected priorities for future funding include support for studies of changing biosphere dynamics, energy systems, educational enhancement, broadening participation, and climate change research.

A representative from the Public Policy Office (PPO) reported that there is a better environment for science funding following the recent presidential election and also new emphasis on greater transparency related to the regulatory process. The PPO is still active in issues relating to the teaching of evolution in public schools. AIBS launched the Legislative Action Center, an online resource that facilitates contact between scientists and legislators. Individuals can register with the Center to receive monthly alerts concerning breaking issues of interest, and then will be emailed letters that can be modified or sent as written. A direct link to the appropriate legislators will be provided. The Legislative Action Center conducted a successful campaign to remove restrictions from the government's economic stimulus package that would have prevented funds from being allocated to museums.

Al reported that BioOne now has two collections (BioOne and BioOne.2) and continues to grow with the addition of new titles. A new platform increases the ease of accessing material. BioOne is conducting a review to determine whether to publish new journals in emerging fields, reference books, and textbooks. The meeting ended with discussion on the future of print publications and continued declines in Society memberships.

SSAR and HL are co-sponsoring the symposium "Headstarting Turtles—Learning from Experience" planned for the 2010 JMIH. Symposium Coordinator Richard Durtsche, reported that SSAR allocated $3,000 in funds. There was discussion of a need to contact members to remind them to be generating ideas for future symposia.

This concluded discussion of reports submitted, and the Board then turned to new business. Breck Bartholomew's proposal to resume providing membership duties was considered by the Board. Our contract with AM&M ends 31 December 2009, and dissatisfaction, both with service and the price of that service, has been expressed. Breck will be able to offer additional services plus those we currently enjoy at a substantially lower cost. The cost will include an initial set up per member, plus 10% of membership dues/member. This cost structure will act as an incentive to Breck to retain and attract new members. He will provide two databases. One will be accessible to Society officers, the other to individual members (will permit logging in to check on status of membership, update personal info, etc.). Additional functionalities will be added when the website is up and running, e.g. wiki-type database, literature database, etc. Electronic voting will be possible. According to Kirsten Nicholson, leaving AM&M has no implications for staying with Allen Press for the printing of journals. The Board voted unanimously to accept Breck's proposal. Breck will begin to set up user profiles within the next month and predicts the membership website will be up and running by October 2009. Membership renewal notification will begin with an email blast in August, and Breck will follow this up with a mailing for bounce-backs and lack of responses. (Note added later: HL, which has a joint agreement with AM&M, has also accepted Breck's proposal).

Roy McDiarmid was contacted in late 2008 by the owner of a US reptile shop offering a donation to the Society (< $1000). There was some email correspondence about what we could do with this donation. The Board discussed the larger issue of accepting such donations, as there was some concern about accepting funds from individuals unknown to the Society, e.g., what are their credentials, are there any strings attached, etc. Roy will investigate this specific case further and the issue of donations will be discussed by the Board at the next Annual Meeting.

The possibility of offering an award for the best student poster(s) at the annual meeting was discussed (this was previously raised at the 2008 Board Meeting). The student award could be a certificate, banquet tickets, and/or a cash prize. A suggestion was made that this competition could be targeted towards more junior students (graduate and undergraduate). Joe Mendelson, III offered to form and chair an *ad hoc* committee to look into this.

Kirsten Nicholson brought to the Board's attention the fact that Allen Press Management is transitioning its association bank accounts from Douglas County Bank to US Bank. The Board decided that acceptance of such a move was up to the Treasurer and did not require its approval.

SSAR presently lacks copyright agreements with authors who have published recently in our journals. Kirsten will draft a copyright agree-

ment and distribute this to the Board electronically for comments and a vote before the next Board Meeting. A suggestion was made that we could allow authors to purchase low cost, high quality PDFs of papers and the authors could then distribute copies as they wish. If they chose to not purchase PDF copies, they then do not have the right to distribute their paper widely as the copyright is held by the Society.

Currently, although the Society is charged for color figures in *Journal of Herpetology*, page charges are not enforced and thus we do not insist on passing this cost along to the authors. After some discussion, the Board indicated that it was in favor of charging for color plates. Matt Parris offered to produce a policy for dealing with this. A suggestion was made that we could give authors a time line to pay for color figures, and until the author pays for color plates the manuscript is not published. This would have to be handled carefully so as to not interfere with layout and scheduling.

Allen Press wants to do away with the mailing sheets that are currently included with *Journal of Herpetology* (these sheets contain membership information which is now on the website). Mailing addresses will be printed on a white stripe on polywrap covers. The Board approved this change.

Brian submitted a proposal regarding the SSAR representative on the Meeting Management and Planning Committee (MMPC). This individual attends the planning meeting in the April preceding the JMIH and would serve a four-year term. Typically this person would be President-Elect or President when they begin their term. There will be overlap in year one of the four-year term with the outgoing SSAR Rep who is in year 4 of their four-year term. Thus, the SSAR rep will overlap with another rep for two years (beginning and end of term) and serve on their own for the middle two years. SSAR will cover the cost of sending the rep(s) to the planning meeting. Because of the scheduling of this scheme, every third President will not serve as SSAR rep; instead, this duty will skip to the next President-Elect in their second year. This scheme (although somewhat complicated), ensures continuity (because of the overlap at the beginning and end of the term) without costing the Society a great deal. If the President or President-Elect is unable to serve (e.g. they might be an international member) a proxy will be appointed from among the officers. This proposal received unanimous support.

The Board returned to the issue of sharing financial responsibility for the JMIH with the other participating Societies. This issue was considered briefly at the Board Meeting in 2008. Several officers (President, President-Elect, Treasurer, Secretary, one Board member) had met informally with officers from other Societies the previous evening to discuss this. The Board voted unanimously to proceed with an investigation of the many issues associated with such an arrangement (including what happens in years when SSAR meets with the WCH) and the generation of a proposal to be considered later.

There was brief discussion of offering an online-only membership. Typically, having this form of membership would reduce membership income, but it might increase overall membership. The fact that *Herpetological Review* is not yet published in an electronic format would need to be addressed before we could move forward with this type of membership. Brian will ask Raul Diaz and Bob Hansen to look into this. (Note added later: Brian, Bob, and Breck have already begun this conversation.)

The Board was in favor of forming a Membership Campaign Committee. Brian will appoint a chair. The committee will include both professionals and students.

Joe Mendelson, III recommended that SSAR consider ways of engaging the media and better publicizing SSAR activities and research published in our journals. There was wide-ranging discussion of this suggestion. The Board voted unanimously in support of the formation of a Media Liaison Committee. In order to better communicate with the public, the Editor of *Journal of Herpetology* could ask authors to submit a second abstract written in layperson's terms. There was discussion of a Presidential essay/op-ed piece to be published biannually on the website and *Journal of Herpetology*. The aim of these pieces would be to highlight

FIG. 6. Kris Kaiser and John (J.D.) Wilson, winners of the 2009 Henri Seibert Awards in the *Conservation* and *Ecology* categories, respectively. These awards were presented at the Business Meeting. Jamie Oaks was the winner for *Systematics/Evolution* and Victoria Ash was the winner for *Physiology/Morphology*. (Photo M. Preest)

SSAR activities, put SSAR in a larger context, etc., and they would make members aware of what SSAR is doing (e.g., conservation and education initiatives) and the fact that SSAR is more than just a publisher of journals. The President could ask others to submit essays. The Editor of *Journal of Herpetology* will contact the President when they are needed.

Steve Godley presented a proposal to make appendices to papers published in our journals available on the website. These appendices could include audio and video files, photographs, databases, etc. ENTRIX employee, Steve Smith, has volunteered to write the programs necessary to host the appendices. Allen Press will not charge us for this and in fact are already set up to do this. The Board voted to support this proposal and Brian will contact Allen Press to pursue this further.

A balanced budget for 2010 of $255,000 was approved and the meeting was adjourned by President Crother at 1440 h.

The Annual SSAR Business Meeting was called to order by President Crother at 1800 h on 25 July. Approximately 24 members of SSAR were in attendance. Officers, Editors, and Committee Chairs who were at the Business Meeting introduced themselves to the other attendees and gave brief summaries of their Annual Reports and relevant information from the Board Meeting. Aaron Bauer (Secretary General, WCH) spoke about the 7th World Congress of Herpetology to be held in Vancouver, British Columbia, Canada (8–14 August 2012). SSAR will meet with WCH in Vancouver and the other participating JMIH Societies will be invited. Pat Gregory (SSAR non-US Board Member) is one of the local hosts for the meeting.

Winners of the 2009 Dean Metter Award, Kennedy Award, Henri Seibert Student Awards (Fig. 6), Grants-in-Herpetology Awards, and Student Travel Awards (Fig. 7) were announced.

Stu Nielsen (Resolutions Chair) read the following 2009 resolutions.

SSAR wishes to acknowledge the dedication and hard work of our Immediate Past-President, Roy McDiarmid. Roy was particularly focused on student participation in the Society and organized a student reception at the JMIH last year that was so successful that we repeated it this year along with HL. He also initiated a change in the format of the Business Meeting to make it more interactive and welcoming to student members. Roy was heavily involved during his term in the highly successful 50th Anniversary Celebration of SSAR, he helped smooth the transition to working with AM&M, and he participated in the ongoing discussion of the role of SSAR in JMIH planning. He continues to be active on behalf

FIG. 7. Two of the ten winners of Student Travel Awards (Gareth Hopkins and David McLeod). In recognition of the high cost of attending the Annual Meeting, the SSAR Board voted in 2008 to increase the Travel Awards from $200 to $400 each. (Photo M. Preest)

of SSAR, particularly in regards to a plan to house the Societies' archives at the Smithsonian.

Four members of the Board stepped down at the end of 2008. They were: Rafe Brown, Meredith Mahoney, Jim McGuire, and Rick Shine. The Society greatly appreciates their efforts on behalf of the Society.

There have been few personnel changes in the last year at *Herpetological Review*. Brent Thomas, an Associate Editor, stepped down at the end of 2008 after a two-year run and was replaced by Margaret Gunzburger. Chris Phillips, another Associate Editor, stepped down in July marking the five-year anniversary of his service to *Herpetological Review*. Michael Jorgensen, a Copy Editor, completed his service as of July 2008 and was replaced by Dan Portik.

As of the beginning of this year, Geoff Smith stepped down as Editor of the *Journal of Herpetology* and was replaced by Matt Parris. Geoff was Editor of the *Journal* for three years and, with Brian Sullivan (the previous Editor), was instrumental in the transition to online submission via AllenTrack. With current Editor, Matt Parris, he updated the *Journal's* Ethics Statement and he continued to uphold the high standard of publications for which the *Journal* has become known. Geoff is processing all manuscripts initially submitted in calendar years preceding 2009.

Breck Bartholomew and Robin Jung-Brown both served as co-Editors on the 3rd volume in the *Herpetological Conservation* series. Urban Herpetology was a highly ambitious project—40 chapters and 13 case studies authored by 120 authors worldwide—and is being very well received. Joe Mitchell will continue as sole Editor of that series.

SSAR wishes to acknowledge Kirsten Nicholson who chaired the Nominations Committee for six years and also the following individuals who agreed to run for Officer positions last year: Joe Mendelson III, Stan Fox, David Cundall, Kevin de Queiroz, Ann Paterson, Lisa Hazard, John Moriarty, Jeff Parmalee, Greg Watkins-Colwell, Alison Cree, and Pat Gregory.

Dawn Wilson served as chair of the Student Travel Awards Committee for more years than we can count before stepping down last year. Her hard work as organizer of the associated Silent Auction has provided funds for well over 100 students to help them cover the costs of attending the annual meetings. Just this year SSAR doubled the amount of money we provide to winners of the Travel Awards. Dawn continues to be very active in the Society—not 30 minutes after stepping down as chair of the Travel Awards Committee at the Board Meeting last year, she was appointed chair of the Student Participation Committee.

Raul Diaz deserves special thanks as our hard-working and talented volunteer webmaster. If you haven't had a good look at the SSAR website recently, you really should!

Stephen Richter stepped down as co-chair of the Conservation Committee at the end of last year. He served as chair and then co-chair for five years. As a result of his efforts (and those of others), this Committee has become increasingly visible and influential. Andy Kouba and Howard Whiteman rotated off the Conservation Committee and we thank them for their service.

SSAR thanks Richard Wassersug who stepped down after serving for three years as Resolutions chair. Thanks to Mo Donnelly for another great President's Travelogue. There was standing room only at her talk on the opening day of the meeting. Joe Mendelson III spearheaded a membership campaign last year targeting members of the zoo, aquarium, and botanical park communities. As a result we have seen a slight upswing in number of members from this constituency.

Henry Mushinsky has served as coordinator of the SSAR/HL Live Auction for more than five years. Although Henry was never the "face" of the auction, he worked tirelessly behind the scenes to ensure that for years we had a smooth running auction with terrific items.

We welcome the increased involvement of students in the Society; in the past year and a half, we have appointed students to serve as Elector, Resolutions Chair, members of the Student Participation Society, Conservation Committee, Student Travel Award Committee, and so on. There's no shortage of work, so if you're interested in getting more involved, speak with President Crother or Dawn Wilson, chair of the Student Participation Society.

Finally, SSAR thanks the many members who serve in various capacities—continuing officers, editors, and members of committees, judges of student competitions, reviewers of manuscripts submitted to our journals, contributors to the Live and Silent Auctions, as well as those who attend these Joint Meetings.

The 2009 Business Meeting was adjourned at 1970 h.

Members of SSAR were greatly saddened early in the meeting to learn of the passing of Dr. Barbara Savitzky at her home in Virginia after a battle with cancer that lasted more than 20 years. Barb had been a member of SSAR since the early 1980s and attended nearly all SSAR meetings since 1987. She and her husband Al first met at the 1986 SSAR meeting in Springfield, Missouri. SSAR extends deep condolences to Al and his family.

—Respectfully submitted by Marion Preest, SSAR Secretary

NEWSNOTES

Slowinski Award Announced for 2009

The Center for North American Herpetology is pleased to announce that the recipient of the Joseph B. Slowinski Award for Excellence in Snake Systematics for 2009 is Kate L. Sanders, University of Adelaide.

On 12 September 2001, the world lost one of its premier herpetologists, a loss that went virtually unnoticed in the wake of the tragedy that befell the United States the previous day. Joseph Bruno Slowinski, the 39-year-old curator of herpetology at the California Academy of Sciences in San Francisco, died in the jungles of Burma from the bite of a venomous snake. Joe was bitten on 11 September and succumbed to the effects of the bite the next day. Eventually, the world took notice and media outlets throughout the

U.S. and beyond chronicled Joe Slowinski's exemplary career, cut so tragically short.

A distinguished committee, comprised of Simon Creer (University of Wales, Bangor), Hussam Zaher (Museu de Zoologia da Universidade de Sao Paulo, Brazil), and Christopher L. Parkinson (committee chairperson, University of Central Florida, Orlando), has deemed the paper "Molecular phylogeny and divergence dates for Australasian elapids and sea snakes (Hydrophiinae): evidence from seven genes for rapid evolutionary radiations" published in volume 21 of the *Journal of Evolutionary Biology*, as the most distinguished paper on snake systematics to appear during 2008. The paper was co-authored with Michael S. Y. Lee, Remko Leys, Robert Foster, and J. Scott Keogh.

As senior author of the paper, Dr. Sanders becomes the seventh recipient of the Slowinski Award, and will receive a check from the Center for North American Herpetology for US $500 along with a commemorative memento in recognition of her achievement.

MEETINGS

Meetings Calendar

Meeting announcement information should be sent directly to the Editor (HerpReview@gmail.com) well in advance of the event.

26–28 February 2010—35th Annual Desert Tortoise Council Symposium, Ontario, California, USA. Information: http://www.deserttortoise.org/symposia.html

16–18 March 2010—Conference: **"**Climate Change and Conservation of Native Amphibians and Reptiles." Hosted by Southwest Region, U.S. Fish and Wildlife Service, Albuquerque, New Mexico, USA. Information: http://www.fws.gov/southwest/Climatechange/amphibreps.html#agenda

30 March–2 April 2010—Biology of the Vipers Symposium, Natural History Museum, University of Pisa, Italy. Information: http://www.msn.unipi.it/vipere/default.aspx

22–24 April 2010—57th Annual Meeting, Southwestern Association of Naturalists, Llano River Field Station, Junction, Texas, USA. Information: http://www.biosurvey.ou.edu/swan/annualm10.html

7–12 July 2010—Joint Meeting of Ichthyologists and Herpetologists (ASIH / HL / SSAR), Providence, Rhode Island, USA. Information: http://www.dce.k-state.edu/conf/jointmeeting/

21–24 July 2010—33rd Annual International Herpetological Symposium, Tucson, Arizona, USA. Information: http://www.kingsnake.com/ihs/

22–26 September 2010—VIII National Congress of Societas Herpetologica Italica, Abruzzo, Italy. Information: shiabruzzo2010.iscrizioni@gmail.com

CURRENT RESEARCH

The purpose of Current Research is to present brief summaries and citations for selected papers from journals other than those published by the American Society of Ichthyologists and Herpetologists, The Herpetologists' League, and the Society for the Study of Amphibians and Reptiles. Limited space prohibits comprehensive coverage of the literature, but an effort will be made to cover a variety of taxa and topics. To ensure that the coverage is as broad and current as possible, authors are invited to send reprints to the Current Research section editors, Joshua Hale or Ben Lowe; postal and e-mail addresses may be found on the inside front cover.

A listing of current contents of various herpetological journals and other publications is available online. Go to: http://www.herplit.com and click on "Current Herpetological Contents."

Basking Opportunity Impacts Birthing Asynchrony in a Viviparous Lizard

Birthing asynchrony, the spread of time over which mothers give birth to a brood of offspring or lay a clutch of eggs, can have considerable fitness consequences for offspring, and the optimal degree of asynchrony may depend on environmental conditions. It is therefore predicted that females with the ability to control the degree of birthing asynchrony would do so to the degree that maximizes the fitness of the offspring. However, the study of birthing asynchrony has been traditionally limited to avian studies, and few empirical investigations have been completed. In this study, the authors examined the impacts of environmental quality on birthing asynchrony in a viviparous skink, *Egernia whitii*. While most reptiles give birth to their offspring all at once, *Egernia* skinks display asynchronous birth. Additionally, it has been shown that *Egernia* juveniles experience a high degree of intra-size-class competition, with smaller (= later born) individuals being driven to disperse (a move that potentially increases their fitness), and that females exhibit control over degree of birthing asynchrony. Environmental quality was determined by a female's access to basking opportunity, with gravid females assigned at the start of gestation to either a restricted (4 hours access to a heat lamp each day) or extended (10 hours access) basking treatment. Offspring of females in the extended treatment were larger and were born earlier than those in the restricted treatment. Furthermore, females held in the restricted basking treatment increased their birthing asynchrony, suggesting that this behavior is under strong selection in this species.

While, G. M., and E. Wapstra. 2009. Effects of basking opportunity on birthing asynchrony in a viviparous lizard. Animal Behaviour 77:1465–1470.

Reproductive Output Not Reduced in Flat Lizards

Differences in size and shape are strong determinants of the reproductive output of most animals. Thus, selection favoring specific body sizes and shapes may have a direct effect on reproductive output (the quantity of offspring and eggs that can be produced). In reptiles, species that occupy rocky habitats are often flattened, a morphological character that aids locomotion and life on rocks, but which may constrain reproductive output by reducing the amount of abdominal space available to fill with eggs or offspring. In this study, examining 20 species of tropical skink from a wide range of habitats, the authors quantified habitat use, body height, body volume, and reproductive output, to determine whether the evolution of a flattened body was correlated with a reduction in abdominal volume, and, in turn, with reduced reproductive output. In this group of lizards, the occupation of rocky habitats led to the evolution of a flattened body, which caused a reduction in abdominal volume. However, despite this reduction in abdominal volume reproductive output was unaffected, as flatter species compensate by being more "full" of eggs. This study demonstrates that morphological adaptation for enhanced performance in specific habitats does not necessarily result in a reduction in instantaneous reproductive output.

Goodman, B. A., S. C. Hudson, J. L. Isaac, and L. Schwarzkopf. 2009. The evolution of body shape in response to habitat: is reproductive output reduced in flat lizards? Evolution 63:1279–1291.

Three Independent Origins of TTX Resistance in *Thamnophis* Garter Snakes

Tetrodotoxin (TTX) is a neurotoxin that disables nervous and muscle tissue by binding to gated sodium channels and is employed in defense by several taxa, including *Taricha* salamanders. Three species of garter snakes (*Thamnophis*) in western North America are known to prey on *Taricha* and exhibit relative immunity to the effects of TTX. This phenomenon has been investigated in one species, *Th. sirtalis*, and it has been revealed that changes in a few amino acids residing on the extracellular portions of the protein responsible for forming the cell's sodium channels ($Na_v1.4$) bestow TTX immunity. As two additional, phylogenetically distant species (*Th. atratus* and *Th. couchii*) display TTX immunity, this phenomenon either evolved independently three times or once and is the result of ancestral polymorphism or horizontal transfer. If TTX resistance evolved once, sequences from resistant snakes would form a clade in the $Na_v1.4$ gene genealogy; if it evolved independently, the $Na_v1.4$ gene genealogy would be largely congruent with the accepted species tree. To address this, the authors accumulated $Na_v1.4$ DNA (and inferred amino acid) sequence data for the two additional TTX-resistant *Thamnophis*, as well as for non-resistant relatives (including non-resistant *Th. sirtalis*). Results showed the $Na_v1.4$ gene genealogy is congruent with the *Thamnophis* species tree (indicating independent origin); indeed the suite of specific amino acid changes bestowing TTX immunity is unique in each lineage. Furthermore, as the $Na_v1.4$ amino acid sequences in the regions of TTX binding for non-resistant taxa are highly conserved (even in humans; evidence of purifying selection), it is highly unlikely that genetic variation present in the common ancestor of *Thamnophis* is the source of TTX resistance. By showing that three unique, diminutive changes in amino acid sequence can result in a single, radically different phenotype, this study provides insight into the importance of large-effect mutations in adaptation.

Crocodilian Vocalization Reviewed

Both extant archosaurian lineages, birds and crocodilians, extensively employ vocalizations in both inter- and intraspecific contexts. In contrast to the deep understanding of avian communication that was achieved in the 20th century, our knowledge of crocodilian vocalization remains inadequate. The authors of this review paper summarize what is known of crocodilian communication. Crocodilian vocalizations can be placed into several categories. Both adults and hatchlings make use of defensive calls to warn off potential predators. Additionally, vocalizations directed toward conspecifics are employed by both adults (courtship and territorial) and juveniles (to coordinate hatching and engender cohort cohesiveness). Crocodilian vocalizations, unlike those of birds, do not originate from a specific, highly developed anatomical structure and are therefore short, simple, and repetitive ("calls"). Contrary to their poorly developed sound production anatomy, crocodilians possess an advanced, tri-partitioned, single-ossicle ear similar to birds; muscular "ear lids" enable them to dive underwater while leaving the outer ear dry (crocodilians are capable of hearing both in and out of water). Crocodilians exhibit a breadth of optimal sound frequencies equivalent to that observed in passerine birds but with a center of optimal hearing slightly lower (resulting in greater sensitivity at lower frequencies). As they are known to emit infrasonic (very low frequency) sounds that would be inaudible via standard sound perception, perhaps an alternate, undescribed mode of crocodilian sound detection exists. The details of the neurological components of crocodilian sound perception are particularly poorly known; understanding of the degree to which they can distinguish between and comprehend different sounds awaits future inquiry.

Cryptic Diversity in Australian Geckos

A number of fields of study require an accurate assessment of species diversity; however, much of the world's diversity remains undocumented. While most unrecognized diversity is found in invertebrates and in developing countries, this is not always the case. Although Australia is a developed nation, with scientific institutes in every state from the nineteenth century, the true species diversity is still not known, even in vertebrate groups. In this study, the authors have examined the cryptic diversity in the Australian gecko family, the Diplodactylidae. Mitochondrial DNA, allozymes, and chromosomal variation were used to examine species diversity in the genus *Diplodactylus*. Results indicated that actual species diversity in this genus has been underestimated, with estimates from this study increasing the number of species from 13 to 29. It was found that four currently recognized species actually represent species complexes, with three of these not recovered as monophyletic. The authors suggest that their study highlights the importance of conducting detailed assessments of species diversity with special attention paid to identifying cryptic species, even in developed countries with conspicuous and well-studied taxa.

Cost of Migration for Female Newts

Partial migration, where a portion of individuals in a population complete a migration, is common among mammals, insects, fish and birds, but is rare in amphibians. The eastern newt, *Notophtalmus viridescens*, is one of the only known amphibian species to demonstrate partial migration, with a subset of the population migrating to terrestrial habitats after the breeding season while the rest remain in the breeding pools. In this study, the authors examined the fitness costs of migration in females of this species in Virginia, USA. Field enclosures were used to sample the egg laying behaviors of resident and migrant newts across the breeding season. Despite resident females being larger than migrants, there was no difference observed in the timing of egg laying or the number of eggs laid. The eggs of resident females did develop into larger larvae than those laid by migratory females; this may be due to the larger size of resident females. The authors suggest that future work should examine the cost of migration for male newts as they expect that, due to male-male competition, mate availability, and sperm precedence, migration may be more costly for males.

Grayson, K. L., and H. D. McLeod. 2009. Evaluating the reproductive cost of migration for females in a partially migrating pond-breeding amphibian. Journal of Zoology 279:71–77.

Nest-site Selection in a Freshwater Turtle

Nest-site choice can have significant consequences on incubation conditions, and in turn, on the phenotype and fitness of hatchlings. In species that lack parental care, nest sites may be chosen by females to maximize offspring fitness; alternatively, nest sites may be chosen for other, non-selective factors, including random nest-site selection and socially induced nest-site selection ("social facilitation," where gravid females simply lay clutches where other conspecifics have chosen to oviposit; an infrequently considered hypothesis). In this study, the authors have examined nest-site choice in the South American freshwater turtle *Podocnemis unifilis* in Venezuela to determine if nest location patterns best represent random processes, adaptive nest-site selection (selection of nest-sites exhibiting environmental conditions which maximize the fitness of the offspring), or social facilitation. Results demonstrated that nest-site selection was non-random; however, environmental conditions at nest sites were not associated with offspring survival. The authors suggest that these results are most indicative of social facilitation. Furthermore, nest sites clustered closely together and laid on the same night suffered lower predation than nests laid on different nights. The authors suggest that selection operating on nest-site choice in this species is likely to be related to maximizing conspecific cues, and less likely to be related to environmental conditions of the nest itself.

Escalona, T., N. Valenzuela, and D. C. Adams. 2009. Nesting ecology in the freshwater turtle *Podocnemis unifilis*: spatiotemporal patterns and inferred explanations. Functional Ecology 23:826–835.

Perceived Beauty of Snakes Consistent Across Cultures

The study of the innate tendency for humans to relate to other animals, termed "biophilia," has revealed, among other phenomena, that categorizations of animals are consistent across cultures. In this study, the authors have examined whether this cross-cultural similarity extends to aesthetic perceptions of snakes. A number of photographs of pythons and boas were shown to people from the Czech Republic and from Papua New Guinea and they were asked to rank the photographs in order of beauty. The perceived beauty of the photographs between the two cultures was found to be tightly correlated. The authors suggest that this result may be important for conservation policies, as humans may be more likely to support conservation of some species over others.

Complete Mitochondrial Genomes Used to Infer Higher-level Salamander Relationships

The family-level phylogentic relationships of living salamanders remains an area of controversy, largely because resolving these relationships is complicated by the fact that salamanders have a long evolutionary history, with diversification occurring within a relatively short time. In this paper, the authors have examined these family level relationships by sequencing seven complete mitochondrial genomes of salamanders from 5 of the 10 families, four of which were not previously represented. Combined with published genomes representing 6 of the 10 families and a number of outgroups, the authors used two different data sets to ascertain phylogenetic relationships: one combined the entire mitochondrial sequence (except for the D-loop region), and the other used the deduced amino acid sequence for the 13 mitochondrial protein coding regions. Two Bayesian-inference programs (Multidivtime and BEAST) were used to perform molecular dating analyses. The analyses of the two data sets recovered similar phylogenetic relationships (discrepancies include the precise placement of Rhyacotritonidae), with each family shown to be monophyletic. The internally fertilizing salamanders formed a clade made up of two well-supported clades: one consisting of Ambystomatidae, Salamandridae and Dicamptodontidae and the other comprised of Proteidae, Rhyactritonidae, Amphiumidae and Plethodontidae. The results also support the hypothesis that Sirenidae is the sister-group to all other salamanders. The dating analysis indicates that the diversification of living amphibians occurred from the Late Carboniferous to the Early Permian, later than previously thought. Further, it was estimated that living salamanders originated in the Early Jurassic, while most families had diversified by the Late Cretaceous.

Nitrate Impacts Male Attractiveness in Newts

Endocrine disruptors released by human activities have been demonstrated to have serious negative impacts on wildlife, both on the fitness of individual organisms and on population dynamics. As endocrine disruptors operate on hormonal systems, they can impact metabolism, development, reproduction and behavior, and are commonly associated with mortality and malformations. However, non-lethal endocrine disruptors can still have more subtle yet still serious consequences for individual fitness and population dynamics. In this study, the authors have examined the impact of a specific endocrine disruptor, nitrate (a chemical commonly used in agriculture), on the expression of male secondary sexual traits in the palmate newt *Triturus heleviticus* from western France. The authors exposed male newts to high (but realistic) nitrate levels and then examined expression of secondary sexual traits: tail height and hind-foot web area. Males exposed to the nitrate treatment for three weeks demonstrated reduced growth and expression of secondary sexual traits. Exposure for 10 days did not have an impact on the expression of secondary sexual traits, but females preferred males unexposed to nitrate levels in olfactory female-choice trials, but not visual trials, regardless of their length of nitrate exposure. The authors suggest that nitrate may alter population dynamics both by interfering with the development of male secondary sexual traits, but also by disrupting the production of olfactory cues.

Secondi, J., E. Hinot, Z. Djalout, S. Sourice, and A. Jadas-Hécart. 2009. Realistic nitrate concentration alters the expression of sexual traits and olfactory male attractiveness in newts. Functional Ecology 23:800–808.

Pathogenesis of Chytridiomycosis

Although chytridiomycosis, the amphibian skin disease caused by the pathogen *Batrachochytrium dendrobatidis* (*Bd*), has been strongly implicated in amphibian declines globally, the mechanism by which it causes death has not been established. In this study, the authors have sought to investigate the pathogenesis of chytridiomycosis by following *Bd* infections in green tree frogs, *Litoria carulea*, in laboratory experiments. The results of histopathology on skin biopsies and PCR analysis confirmed that disease symptoms and mortality occurred in individuals with the highest levels of *Bd* infection. The authors also monitored epidermal electrolyte transport in skin preparations, changes in blood and urine biochemical parameters and cardiac electrical activity from clinically diseased, aclinical and control frogs. Electrolyte transport across the skin was inhibited by greater than 50% in samples from diseased frogs and sodium and potassium levels in the plasma were also significantly reduced. As there was no observed difference in water volume, the authors suggest that the decreased sodium and potassium levels observed in diseased frogs are a result of reduced sodium and chloride channel activity, rather than dilution by water. The authors suggest that these epidermal channels are potentially disrupted by the release of fungal toxins, or by direct damage to infected host cells. Frogs in the terminal stage of infection were administered an oral electrolyte treatment and did recover some function and lived more than 20 hours longer than untreated frogs. While this treatment does have some efficacy, the authors suggest that unless epidermal damage can be revered it will not prevent death from *Bd* infection. Cardiac electrical activity of severely diseased frogs in the final stages of life resembled cardiac standstill, or cardiac arrest, which the authors suggest is related to the electrolyte level abnormalities, and is likely to be the proximate cause of mortality in chytridiomycosis.

OBITUARIES

Herpetological Review, 2009, 40(4), 393–400.
© 2009 by Society for the Study of Amphibians and Reptiles

Henry S. Fitch (1909–2009): Field Notes on a Wonderful Life

Henry Sheldon Fitch passed away on 8 September 2009, just a bit shy of his 100th birthday (25 December). In lieu of a traditional obituary, and because an autobiographical account of his life recently appeared (Echelle and Stewart 2000), several former students and colleagues each describe their personal memories of the man deservedly referred to as the "father of snake ecology." Although each of the remembrances brings a different perspective, three common threads run through all of them, namely: Henry Fitch's energy, enthusiasm, and decency.

Henry Fitch and the Practice of Natural History

HARRY W. GREENE
Department of Ecology and Evolutionary Biology
Cornell University, Ithaca, New York 14853, USA
e-mail: hwg5@cornell.edu

Texas Alligator Lizards were first described from the Devil's River in 1858 and a century later, when I encountered them in photographs, there was still almost nothing known about those snaky, bright-eyed reptiles. As a Missouri youth, hungry for wilder places and imagining myself a trailblazing naturalist, I pored over accounts in Hobart Smith's *Handbook of Lizards* of two related West Coast anguids—especially field studies by Henry Fitch, who referred to them as "unusually intelligent" and saw a Southern Alligator Lizard hold off Yellow-billed Magpies by hissing and threatening with open jaws, tail curled forward like a shield. Someday, I thought, I'll roam the Mexican borderlands and learn something exciting about *Gerrhonotus infernalis*!

Fitch's photo also caught my attention among the "influential saurologists" profiled in Smith's *Handbook* because he wore a World War I cavalry hat and looked intense, as if distracted from some important task. His publications in our local college library provided a University of Kansas address, so I wrote announcing my upcoming herpetological career and asking questions about proposed Texas fieldwork. However pretentious that letter, right back came Henry's cordial, hand written explanation of how to sex alligator lizards: "By grasping the base of the tail, gently twisting it, and exerting pressure with the thumb ventrally, one can cause a hemipenis to be exposed. Failing in several such attempts, one may be reasonably sure the specimen is a female."

I knew ventral meant underside and penes were for copulation, but couldn't have realized a high school internship with Henry would set my course or that he would author almost 200 publications, more than 4,000 pages on plants, snails, spiders, and diverse vertebrates. This unassuming man started graduate work at Berkeley's Museum of Vertebrate Zoology in 1931, when the discoveries of Charles Darwin and Alfred Russel Wallace were still relatively fresh, and took his first academic position in 1948, five years before James Watson and Francis Crick unraveled DNA. Decades later, after Henry summarized half a century of fieldwork at a symposium in his honor, a graduate student wryly noted that thanks to him she couldn't call four years of horned lizard population research "long term." Applause typically occurs *after* presentations, but his arrival at the podium that day provoked a standing ovation before he began speaking.

With Henry's passing I want to honor his impact on biology and me personally by reflecting on a conundrum. Although Darwin, Wallace, and countless others have been drawn into nature by orchids, beetles, or whatever seized their fancy, and this is surely truer now than ever before, acclaim typically comes from generalizing rather than gathering facts. Ernst Mayr, for example, was renowned for evolutionary theory and less widely so for describing more than 400 new species and subspecies of birds. At first glance then, Henry's career-long focus on organisms seems anachronistic, the widespread esteem in which he's held a bit surprising. In a forthcoming book, *Tracks and Shadows: Field Biology as Art*, I've set out to illuminate that stature as well as more generally assess the enduring values of natural history. Here I'll draw on correspondence and interviews of my teenage mentor, with the goal of addressing a question: why did he do it?

HSF and Rainbow Trout: ca. 1920 at Klamath Lake, Oregon. Photo courtesy of Alice F. Echelle.

One of our extended dialogs was soon after Henry had fallen and spent a chilly night stranded in a creek, and except for the incident's notoriety he seemed surprisingly unfazed —search dogs were hopelessly confused because his scent trail was *everywhere* on the Reservation, and he'd been conscious when helicoptered to a hospital. Daughter Alice was visiting her folks, and we talked all afternoon and late into evening. Almost 80, with raven black hair, Virginia served fried chicken, mashed potatoes with gravy, corn on the cob, and home-made rolls, and she fairly sparkled as conversation meandered from our first visit and the whereabouts of former graduate students to details of Fitch family life. When I smiled at her mention of "youthful indiscretions," Virginia said she married young and divorced the other guy. "Then," she exclaimed, grinning at me and hugging her husband from behind his chair, "I met this wonderful guy!"

From time to time I checked a list of questions, and although in correspondence Henry had been enthusiastic about my book proposal, his answers weren't effusive. I'd known this wasn't going to be easy, if for no other reason than constitutional reticence—as Randy Reiserer wrote in a dissertation acknowledgment of his undergraduate advisor, "I never met anyone who can say so much with so few words, or indeed, without any at all." But I wanted to understand why Henry does the work, keeps catching still more snakes, and what the practice of natural history meant to him, so finally I blurted out something about having my own problems shrink in the face of grandeur and diversity. "Sounds good to me" was all he said, with a soft chuckle and maybe a hint of irony.

I also hoped to learn how Henry knew what to record, given he began gathering data in the 1930s for which there were no guiding theories. His papers typically set forth the ecology of target species, with insights woven among empirical findings—the thesis work on alligator lizards, e.g., addressed advantages of viviparity by noting that "Eggs left in the ground are exposed to…egg-eating reptiles, mammals, and insects, and to extremes of temperature and danger of desiccation, while those carried by the female probably stand a better chance of developing into independently successful young." In 1949 he'd laid out in *Ecology* details of *what* to write down, but almost nothing as to *why* particular information would interest other biologists. And in 1966 Robert MacArthur and Eric Pianka's brilliant paper on optimal foraging would inspire widespread measurement of parameters that Henry had been recording for decades

with no conceptual prompting.

So I kept coming at the questions from various directions, hoping Virginia and Alice would jump in with something definitive or nudge him for details. My query about god resulted in a slight pause and "I have no religious beliefs although raised in that environment. Natural history does it for me." Asked about favorite habitats, Henry attributed his preference for deserts, "because they are open and have interesting animals," to a Nevada field trip during graduate school. At the mention of favorite species, he responded "alligator lizards, Copperheads, and gartersnakes, because they have interesting natural histories." By evening's end the best I could get was "my initial interest in zoology was innate" and "I wrote down everything that interested me."

Two years later I was back trudging up a hill on the Reservation. Henry was audibly winded as we crested the familiar limestone ridge and explained without a trace of self-pity that he'd lost stamina but hoped to complete one more field season. Otherwise he seemed no different than my last visit and at 91 his hair was light brown. He walked slightly stooped, in work boots with visibly thin soles, and was wearing khaki pants, a Berkeley herpetology course t-shirt, and a baseball cap decorated with various university insignia. The tattered cotton bag stuffed through his belt, custom made by Virginia, was for carrying snakes back to the house. He used a smooth, sturdy stick with a nail head protruding on the bottom to steady himself, hold onto tree limbs, turn over cover items, and probe matted grass for the long narrow tin pieces he'd laid out to attract snakes.

As our conversation turned to current projects, Henry spoke with quiet fatherly pride of a paper with Alice about changes in tree diversity over the past 50 years at the Reservation. Their findings were thought-provoking: Once largely prairie, perhaps the best-known square mile in North America had lost a third of its fauna since he arrived because of fire prevention, lack of grazing, and forest encroachment. On the bright side, there were still Bobcats and Timber Rattlesnakes in the vicinity, and a Black Bear was seen near here recently. As we returned to the house he pointed out a large cedar by the driveway, planted many years ago as a tiny family Christmas tree.

That night Henry sat in the front row for my campus lecture on organisms as the central focus of biology, during which I held up his capstone opus, *A Kansas Snake Community*, and introduced my teenage hero. I praised Henry's contributions to ecology and systematics, then said his greatest legacies are immediate products of the work itself—tens of thousands of observations archived, many museum specimens collected—and that in the scholarly tradition of his Berkeley advisor, Joseph Grinnell, he'd bridged Darwin's synthesis with twenty-first century science. As it happens, those individual organisms he studied demonstrated such things as substantial shifts in Copperhead diets over the decades, as prey populations responded to the habitat changes he documented.

Henry's accomplishments amounted to several better-than-average careers, I told the K.U. crowd, given his California and Louisiana work, decades at the Reservation, and his tropical expeditions. In fact, although mainly known as a herpetologist, his publications on mammals would eclipse those of the average "mammalogist." During the lecture I showed photos of island Cottonmouths that eat fish regurgitated by seabirds and have exceptionally large young, exemplifying, I pointed out, unusual and unexpected opportunities for research and enlargement of theory. Afterward Henry asked about the number of young in island snake litters, said he'd enjoyed my talk and our hike, then added with a characteristic grin and swing of the chin, "Oh, and thanks for the plug!"

Work can be a job, a career, or a passion, and for Henry the practice of natural history was all three. When I complained about funding he responded "I have always spent my time on whatever interested me—with or without grants—and have greatly enjoyed all my projects, especially the fieldwork." In his eighties he was quoted in a book on Kansas personalities, "I wouldn't change a thing. People who work with animals in the field, whether snakes or birds or rodents or monkeys, find it deeply satisfying and wouldn't trade it for any other kind of career—even though

HSF and Virginia Fitch in 1975 at the University of Kansas Natural History Reservation (now the Fitch Natural History Reservation). Photo by Michael V. Plummer.

it may not be very financially rewarding." And in 1995 he wrote Alice, "If as a young person I could have dreamed of my future and the world I would like to see, it would have been about the same as the life I have had. Getting a Ph.D., having a loving, supportive wife, children like you and John and Chester, grandchildren like Tyson, Lena, and Ben, living on the Reservation, teaching natural history, studying anoles and pitvipers, and making two dozen trips to nine countries in the tropics for herpetological research have all been great experiences."

One visit, after the Fitches walked me to my truck, I drove back to Lawrence on a sultry Kansas night. A huge moon shone through fog and orange lightning flashed over surrounding fields as I pondered my admiration and affection for Henry. What, I wondered, makes him *tick*? Certainly he marched to his own drummer, unmindful of fads, which makes it all the more fascinating to contemplate his accomplishments, as well as how that stance affected his life more broadly. Maybe verbal frugality reflected limited interest in analytic thought, personally and professionally, which if nothing else protected him from the pettiness so common in universities. Maybe he was always so much within himself that he simply didn't pay much attention to theorizing. And maybe those like Henry who go deeply into nature as children—he was catching snakes as a five-year-old—are especially prone to immersion as adults. We have to be out there.

Just weeks before Henry died he asked Alice and her husband Tony Echelle, if they might visit a local creek and catch watersnakes. When she replied, "Well, what then dad?" he said simply, "We'll mark and recapture them." Evidently the answers to my questions are equally straightforward: Henry was always driven by passionate curiosity and a penchant for detail, accentuated by parental encouragement, and those attributes combined in grad school with a framework for understanding biological diversity that harked back to Darwin and Wallace. That was enough. His approach worked, against formidable odds at times, and he was not inclined to do otherwise. A special gift for field biology and quiet but stubborn confidence must have been obvious to Grinnell in 1931, when an unusually shy but promising new student arrived at Berkeley, fresh off an Oregon pear ranch. Those traits were undiminished to the end, and Henry's long, happy life was inseparable from the quest to understand nature.

Reminiscences of Henry S. Fitch

WILLIAM E. DUELLMAN
Biodiversity Institute, University of Kansas
Lawrence, Kansas 66045, USA
e-mail: duellman@ku.edu

For the past half century I was fortunate to have been a colleague and friend of Henry S. Fitch. During that time, we served on doctoral committees of one another's students, co-advised some graduate students, and team-taught a graduate course in reptile biology. Although we never collaborated on a published paper, we each named a species of *Anolis* for the other. Henry avoided university politics and only reluctantly attended departmental meetings. Many of his colleagues mused that Henry lived in his own little world. But that world was much larger than they thought. He was at home on the University of Kansas Natural History Reservation (subsequently named for him), where he conducted intensive studies on the ecology and behavior of reptiles. Over the years he witnessed the succession of hardwood forest on the reservation, while methodically searching this square mile of land, capturing and recapturing thousands of snakes, and logging hundreds of pages of notes. His dedicated efforts culminated with the publication in 1999 of "A Kansas Snake Community: Composition and Changes Over 50 Years."

However, Henry had a long and distinguished publication record before this finale. While at the University of California at Berkeley prior to moving to Kansas in 1948, he published a classic work on alligator lizards in 1935 and a highly perceptive work on western garter snakes (*Thamnophis*) in 1940. Two of his best-known works are on the natural history of reptiles, especially that on the Five-lined Skink in 1954 and his exhaustive study of the Copperhead in 1960. In addition to these systematic and ecological studies, Fitch provided us with important syntheses—reproductive cycles in lizards and snakes (1970) and sexual size differences in reptiles (1981). Consequently, his publications are cited extensively. A number of years ago, while Fitch was still an active member of the department, the chairman took it upon himself to tally citations to publications by all members of the department. For several consecutive years, Henry Fitch was the most cited.

During the warmer months of the year, the major exception to conducting field studies were the basketball games on the "sand lot" by the Fitch's residence. Games would involve all members of the family and anyone who happened to be visiting the reservation. Henry displayed his usual dogged determination from his fieldwork to the basketball "court," and one quickly learned to avoid his elbows under the basket.

In 1967 I introduced Henry to the tropical rainforest in Amazonian Ecuador, where he was the only member of the field party who would work in the field during the torrid afternoons, all the while lamenting the apparent absence of snakes. Customarily he went into his cabin and emerged a few minutes later with a towel wrapped around his middle and untied sneakers on his feet. To get to the dribbling bamboo spout loosely referred to as the shower, he had to cross the dirt "courtyard," the home territory of a very aggressive goose, which took particular delight in nipping at Henry's buttocks. One afternoon we heard Henry exclaim "ouch," as he stood naked snapping his towel at the goose. He was completely unaware that he was the "floorshow" in the middle of camp.

Here I learned that Henry had poor night vision and consequently was primarily a diurnal biologist, but he was constantly amazed that we found so many snakes at night. Only after much cajoling did he accompany us twice on nocturnal forays during a month in the forest. However, I like to think that I influenced much of Henry's subsequent work in the tropics, where he conducted numerous studies on the systematics and ecology of anoles and on populations and conservation of iguanas.

Henry Fitch was one of the last remaining naturalists. His breadth of knowledge was matched by very few of his contemporaries and scarcely imagined by his younger colleagues. His careful work on natural history is well worth emulating. Our knowledge of animals in nature would be far greater if many more biologists around the world followed in the footsteps of Henry S. Fitch.

Memories of Henry Fitch

MICHAEL V. PLUMMER
Department of Biology, Harding University
Searcy, Arkansas 72149, USA
e-mail: plummer@harding.edu

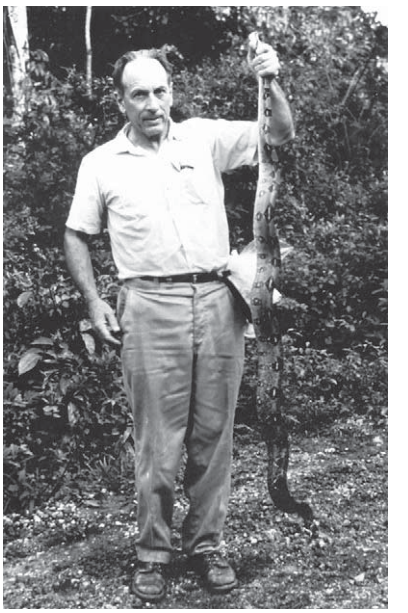
Henry Fitch was one of the most gracious, kind, and gentle men I have ever known. I greatly respected him for his long list of professional achievements, but I also respected him for the man he was and how he treated others. He was always the gentle encourager to me and I often think of his example when I get in an exasperating situation with my students or colleagues. I never heard a degrading word spoken against Henry the man by anyone. Any and all who happened to come by the Natural History Reservation were heartily welcomed by Henry and his lovely wife Virginia, and that seemed to happen frequently.

My formal association with Henry began in July 1972 when I came to KU to begin a Ph.D. program. I found it difficult to believe I had the opportunity to work with such a professional giant. I remember standing in awe as we spoke about potential research projects and thinking that since Henry was 64 at the time, I just might be his last student before he retired (wrong! I only missed by about 30 years). Henry was THE man as far as snake ecology was concerned and I assumed my dissertation would become yet another monograph of a Reservation snake species. But then he suggested we go down on the "Kaw" (Kansas River) to look for softshell turtles. I was fascinated by the sandbars, the softshells, and Henry's nonstop fountain of knowledge about them – talk about information overload! But what I remember most about our inaugural softshell trip was this 27-yr-old kid in the prime of life trying desperately to keep up with an aging 64-yr-old walking (more like running) on the soft sand as he talked. I looked for a red "S" on his chest.

Henry once had a guest at the Reservation, a gentleman from the Bombay Natural History Society, and because India is near the center of softshell diversity, Henry asked me to take the gentleman out on the Kaw and show him our American softshells. By that time, I had captured hundreds of *Apalone mutica* and I assured Henry that it would be no problem seeing numerous softshells. Any field biologist could probably guess what happened. After working hard for a couple of hours, we saw maybe two or three juvenile softshells. I learned that day that one should never make such rash statements regardless of how confident he is about seeing animals in the field. Henry was apologetic to the gentleman and I was embarrassed, but Henry never said another word about it to me.

Henry frequently encouraged his students to do "interesting" side projects along with their thesis or dissertation work. He suggested a project on softshell glands in the summer of 1972 that would fit in "nicely" with my ecological Ph.D. work. Being a swamped and overwhelmed new grad student, I wasn't terribly interested in his suggestion at the time, but I never forgot it (probably because of who suggested it). Well Henry, you would be pleased to know that I finally did do the project and it was published in 2009 just before you left us. Sorry I'm so slow; it only took 37 years. Thanks for the treasured memories.

Henry Fitch at Home and in the Tropics



ROBERT W. HENDERSON
Section of Vertebrate Zoology, Milwaukee Public Museum
Milwaukee, Wisconsin 53233-1478, USA
e-mail: henderson@mpm.edu

I was, herpetologically speaking, incredibly green when I entered the University of Kansas as an undergraduate in 1967. The attraction of KU was its long history of herpetological fieldwork in the Neotropics, and I was aware of the ambitious research program of William Duellman and his students in, at that time, Ecuador. I was not, however, aware of the existence of Henry Fitch. I did know that I wanted to study the way snakes lived, but I had absolutely no idea of how to do it or that anyone was already doing it. Eventually, while browsing through the library in the herpetology division, I came across *Autecology of the Copperhead*. I read it from cover to cover, realized this was the kind of research I wanted to do, and I had to meet Dr. Fitch, who just happened to teach at KU.

The Fitches lived on the grounds of KU's Natural History Reservation and I became a frequent visitor, often making the rounds of coverboards (sheets of tin) in Quarry Field to collect the Prairie Ring-necked Snakes on which Dr. Fitch was then working. I have fond memories of the warm hospitality of Virginia Fitch, energetic basketball games played on the bare ground at the Reservation, the Fitch's yellow VW bug with the smiling happy face stuck to the roof, and of many seemingly carefree hours tramping over the Reservation and encountering Osage Copperheads, Eastern Yellow-bellied Racers, and Prairie Kingsnakes. Despite the time we spent together while I was an undergrad, I somehow convinced Dr. Fitch to take me on as a graduate student, and thus began a 30-year collaboration.

Although my primary interest was in snake ecology, and Dr. Fitch's long-term snake population studies continued to be the focus of his Kansas fieldwork, we never collaborated on a research project with an ophidian concentration. Our tropical fieldwork always had lizards as our primary objective. Mexico was the scene for our first field trip together, primarily in the states of Chiapas and Oaxaca, to collect ecological and morphological data on various species of *Anolis*. This was followed by travels in Nicaragua and Belize for work on the conservation of *Iguana* and *Ctenosaura*, and then more Mexican fieldwork (where one night he suggested we bathe in the Pacific at about 10 pm; I was terrified, certain some creature would lop off my legs while I tried to get clean). Aside from the many hours spent in a truck or jeep, once at a site there was little downtime. On weekends in Nicaragua, we did not have access to the jeep and driver provided for iguana work, but Dr. Fitch knew that anoles awaited us somewhere, so off we went with local transportation, never quite knowing where we were headed or if we'd get back to our quarters in Managua. It was exhausting fun.

I became enamored of the West Indies in the late 1970s, and was pleased when Dr. Fitch joined me in the Dominican Republic (DR) for a project with *Anolis bahorucoensis* in 1985. I know he had a good time in the DR because he kept commenting on the numbers of lizards encountered everywhere all the time. He came up with one wonderful idea after another on how best to study this elusive anole. He later returned to the DR to study the invasive *Anolis cristatellus* and its impact on native anoles in the La Romana area. Cumulatively, we spent months together doing fieldwork in the tropics. Dr. Fitch's energy and enthusiasm for looking for lizards and snakes never waned and, although I was much younger than he, it was not always easy to keep up with him. He had no qualms about sleeping in crummy hotels and, despite his diabetes, he could be pretty malleable when it came to food (although we ate Spam and boiled potatoes *every* night for six weeks in Mexico). I sense Dr. Fitch never lost the enthusiasm I last observed more than 20 years ago, and that's borne out by his incredible productivity well into his 90s. As he noted in an interview conducted by his daughter in 2000 (Echelle and Stewart, 2000), "interest in reptiles and amphibians has been a dominant influence in my life, and other interests have seemed relatively minor." I recall him telling me about one of his KU colleagues who went off on a two-week fishing trip. He intimated that he would not be able to stand doing that, and seemed genuinely perplexed that his colleague could forego research for that long.

HSF and *Boa constrictor*: Taken in February 1972 in Chiapas, Mexico. Photo by Robert W. Henderson.

Dr. Fitch was the ideal collaborator: He always met deadlines (and expected the same from me), and was generous in sharing authorship. I'm sure I must have tried his patience many times (while a student, often showing up at his home unannounced to discuss some "important" issue), but he never visibly lost it. Even a minor falling-out was quickly forgotten. He did, however, at one time inform me that I was no John Lynch or Marty Crump!

While he was alive, Henry Fitch was an inspiration to me and I consider myself amazingly fortunate to have been one of his students and collaborators. He remains my herpetological inspiration and I'm confident that his incredible body of work will continue to inspire researchers for many decades to come. We spoke infrequently on the phone during his last years on the Reservation (and before moving in with his daughter and son-in-law in Stillwater, Oklahoma), but one of our last conversations was my favorite. I don't recall the exact wording, but you'll get the idea.

RWH: So, you must be, what, 91 or 92 now?
HSF (chuckling): No, 93.
RWH: Well, how're you doing?
HSF: Not so great. I have a bad hip and my back is painful, so getting around is difficult.
RWH: I'm sorry to hear that. No fieldwork, I guess.
HSF: Ah, well I just came back from radio-tracking six Timber Rattlesnakes.
RWH (shaking his head in awe and admiration): Amazing.

I always hoped he knew how much he had influenced my efforts and I was looking forward to sending him a copy of a forthcoming book on the natural history of West Indian amphibians and reptiles. I doubt that he would've been up to reading it, but I did want him to know that I had written it (with Bob Powell). Perhaps my ego (or insecurity) hoped he'd at least think, "Bob's done OK."

In the Field with Henry Fitch

DAVID M. HILLIS
Section of Integrative Biology, University of Texas
Austin, Texas 78712, USA
e-mail: dhillis@mail.utexas.edu

I received a phone call from Alice Fitch Echelle in the fall of my junior year at Baylor University. I knew Alice, Henry Fitch's daughter, through her husband Tony Echelle. Tony was teaching a graduate course in Systematics at Baylor, and had given me permission to enroll in his class as an undergraduate. That course opened my eyes to the exciting possibilities of phylogenetics. Tony and Alice often let me come along on their many

field trips to collect fishes throughout Texas, so Alice knew that I was enthusiastic about fieldwork.

Over the phone, Alice described how her father had received a small grant to study the impact of human exploitation of iguanas for food, and was planning a semester-long field trip through Mexico and Central America. As Henry was nearing retirement, Alice was worried about him making the trip alone, and she knew that I had a passion for anything to do with herpetology. She wanted to know if I was interested in taking off a semester from school and accompanying Henry in the field.

"I would love to do it, but I'll need to think about it," I said, as I considered how delaying my graduation by a semester might affect my future plans for graduate school. I hung up the phone and thought for about 30 seconds, then called Alice back. "I'll do it…when do we leave?" That was the extent of the background and the planning for what was to be my most educational semester as an undergraduate.

I was already quite familiar with Henry Fitch through his books and research articles. I had met him the previous summer as he visited Alice and Tony, when I asked him to sign my copy of his book, *Reproductive Cycles of Lizards and Snakes*. I remember that he was pleased to see that my copy of the book was worn and obviously heavily used. Henry had been embarrassed and modest, acting as if he felt honored to be asked by an over-eager undergraduate for his autograph. I couldn't believe that such a famous person could be so modest.

Henry drove down from Kansas and picked me up in Texas in early January, in an old International Harvester pickup with a well-worn camper in the bed, which was to be our home for the next four months. We crossed into Mexico the next day, and I learned very quickly that there was little justification for Henry's modest demeanor. I asked questions about everything we saw, and rarely did I manage to stump him. At every camping site, I caught practically every herp, fish, insect, spider, crustacean and mammal that I could find, and Henry told me something about them all. He also would frequently explain fundamental concepts of geology, climate, ecology, and just about every other aspect of natural history as we slowly moved south through Mexico into Central America. His impromptu lectures stimulated me to write long entries in my field journal every evening.

The funded purpose of the trip was to study iguana exploitation, and we did that. But Henry was fascinated with anoles, and it became clear to me that Henry was much more interested in studying the systematics, ecology, and behavior of anoles than he was in studying iguanas. That was fine with me; I didn't care what we studied, as long as it was related to herpetology. We traveled fairly slowly, so that we had plenty of time to collect anoles and other herps at every campsite.

I had never before met an adult who was so completely immersed in the study of natural history, so we hit it off immediately. Henry was as enthusiastic about being in the field as I was, at least by day. I was surprised, however, that Henry did not accompany me on my nightly forays into the forests around our campsites after dark. His diabetes had affected his night vision, and so he did not see well at night. But he was always enthusiastic about all the herps I would find and bring back to him in the camper after dark, and we would often stay up late talking about our latest captures and what interesting research problems they might suggest. To Henry, every species provided new questions that were waiting to be answered. I couldn't imagine a more exciting life.

As much as I was enjoying myself, there were a few aspects of Henry's approach to fieldwork that caused me some aggravation. First, he insisted on doing all the driving, even though I'd been asked by Alice to accompany Henry on the basis that he would need some help. Given his poor night vision, his night-driving proved quite frightening to everyone on the road except Henry, and more than once I was convinced we would drive off one of the many precipitous roadsides in the mountains of Central America. Eventually, I insisted that he had to let me drive at night, or else I would only get in the truck with him by day. We drove only by day from then on; I was still not permitted to drive the old International Harvester pickup.

A second minor aggravation was what can generously be described as Henry's rather parsimonious nature. We bought and cooked all our own food, which was fine with me, except that Henry was a straight Midwestern meat-and-potatoes man, and we almost never had any meat. So we ate mostly potatoes. After the first few weeks of a steady potato diet, I was getting desperate for something I could taste. I started buying a few peppers and spices from the markets on the sly, and catching land crabs, freshwater prawns, and fish from the streams around our campsites. Soon I was cooking up two meals: boiled potatoes for Henry, and a spicy concoction of whatever I could catch around our campsites for me. Henry politely tried my attempts at culinary diversity a few times, but he always returned to potatoes for dinner. Sometimes, for excitement, he would put a little salt and pepper or butter on them, or even add a scrambled egg when he was feeling extravagant.

HSF examining an iguana in a market in El Salvador, February 1979. Photo by David Hillis.

Other than gasoline (which cost about 30 cents a gallon in Mexico at the time), I think Henry was spending less than dollar a day for all our other living expenses. So when we reached the Guatemala–El Salvador border on a Saturday in February, and Henry discovered that the weekend fee for crossing the border was 50 cents/person, but that the weekday rate was 25 cents, we of course had to turn around and camp out in Guatemala until Monday morning to save 50 cents. At our Guatemalan campsite near the border, I found synbranchid eels in a small stream, and I had a blast figuring out how to catch them (and I still have fond memories of *Synbranchus* stew). By Sunday I had to hang my clothes out to dry, and some locals who had been drinking decided to take advantage of the situation. They grabbed my clothes and ran, and I briefly gave chase, until one of them turned and pulled out a machete. I returned to camp and suggested to Henry that we might want to find a new camping spot. Henry did not seem very interested in doing so until rocks started raining down on us from the cliff above our campsite. We pulled out just as a large rock smashed our windshield. When I last saw that pickup many years later, that broken windshield had never been repaired.

On Monday morning after the windshield-smashing event, we arrived at the border at 8 AM, just when the weekend rate was supposed to change back to the weekday rate. But after the customary spraying of the truck with DDT (a ritual that was practiced on both sides of every Central American border), the border official charged us 50 cents a person. Henry objected, and pointed to the clock on the wall, which said 8:05 AM. The border official calmly went to the clock, changed the time to 7:55, and charged us the weekend rate. It was one of the few times in four months I saw Henry mad about anything. For the most part, he would roll with whatever life dished out, and make the best of every situation.

Our study of human exploitation of iguanas and ctenosaurs reached a peak during Lent, when the markets of Central America became well stocked with these large lizards (see Figure 1). Lizard is not considered "meat" by many people who give up meat for Lent, so iguanas and ctenosaurs were sold and eaten by the thousands during this time. But after Lent, we were back into the mountains, looking for more species of anoles. By then, we had hatched a project to study intra- and interspecific variation of anole dewlaps, and were busy collecting series of as many species as we could locate.

One might think that it would have been a physical mismatch to pair a young strapping undergraduate with a professor nearing retirement on an extended field trip. It was…I had a hard time keeping up with Henry. He wasn't fast, but he never stopped. He could walk all day up steep mountainsides in pursuit of the next species of anole, and we did so just about every day. Some years later, as a graduate student at the University of Kansas, I would take public education classes of schoolchildren out to the KU Natural History Reservation where Henry and his wife Virginia lived. Even well into his "retirement" years, Henry took great pride in leaving kids in the dust. As he cruised through the Reservation, he would grab snakes as he walked, checking their ventral clips for individual identification. "Aha! It's female number 1675! I have captured this racer more than 300 times in her life…I am glad to see that she is still alive." The kids were always wide-eyed with amazement, as they stood there trying to catch their breath before Henry rushed off to the next snake.

As it turned out, Alice need not have worried about Henry's "advancing age" when we set off for our Central American field trip. Henry remained active in the field for another three decades after that trip…a full career for many people. Henry collected more data after he "retired" than most people collect in their lifetimes. I doubt anyone will ever be able to repeat the kind of long-term autecological studies that he perfected. But more than the specific knowledge that I learned from Henry, what I admired most about him was his child-like enthusiasm for nature and everything in it, and his unquenchable need to ask questions about everything he encountered. Several generations of herpetologists benefited from his wisdom, his kindness, and his passion. Mention his name to anyone who ever met him, and you will get a smile and story. I can't think of a better legacy for a great naturalist who squeezed so much out of such a long and productive life. Henry, we will all miss you, but we will smile every time your name is mentioned.

Henry Fitch as a Mentor and Teacher

RICHARD A. SEIGEL
Department of Biological Sciences, Towson University
Towson, Maryland 21252, USA
e-mail: rseigel@towson.edu

Most herpetologists today know Henry S. Fitch only as a name on his classic papers and monographs (e. g., *Autecology of the Copperhead*, *A Kansas Snake Community*). In this remembrance, I would like to give my perspective on Henry in the roles I knew him best, as a mentor and teacher.

In 1979, all I knew about Henry Fitch was his outstanding publication record. I had been accepted to the Ph.D. program at the University of Kansas for the fall 1979 semester, and, through a series of letters, Henry had tentatively agreed to accept me as his doctoral student. However, he had cautioned me that he was retiring in 1980 and that I might want to reconsider coming to KU as his final student. Thus, in June 1979, my wife Nadia and I drove to Kansas to meet Henry and his wife Virginia for the first time. Little did I know that this initial meeting would lead to a 30 year relationship with Henry and Virginia and that my appreciation and respect for them would go far beyond anything I might have expected.

As we drove on the unpaved entrance road leading to Henry's house on the KU Natural History Reservation (now the Fitch Natural History Reservation), I saw numerous metal coverboards ("shelters" in Henry's terminology) and drift fences scattered at what appeared to be random intervals along the road. As soon as we reached the small, incredibly modest house where the Fitches lived on the Reservation, Henry and Virginia were out the front door to greet us. Almost immediately, I gained an insight into Henry's character: Knowing what to call your presumptive major professor is always a delicate proposition for a new student ("Dr. Fitch?" "Professor Fitch?"), but Henry dealt with that by holding out his hand and introducing himself as "Henry Fitch," and we were on a first name basis from then on. Virginia went even further and gave Nadia and me a huge hug, inviting us in for lunch.

Feeling much more at ease, we only got to the Fitch's front porch when I saw that there were a large series of jars, cans, and snake bags, all holding various live herps. Asking Henry where these came from, he proceeded to tell us that was today's catch and then tell much more about the ecology and natural history of his "finds" than four years of field work and reading had provided me so far. I was struck especially by the detailed notes Henry took on each find and how much data he was extracting from each individual.

After lunch, Henry suggested that we do "a round" of his traps and shelters, and the two of us set off up the hillside by the house. Within minutes I discovered that this 69-year old man was in better shape than most grad students, as he went up the hill on what felt like a trot. As we went, he began to tell me a detailed history of what felt like every tree and critter we saw. Phrases such as "I am hearing a Yellow-billed Cuckoo" were thrown out casually, leading to two thoughts I dared not express: "I thought this was a herpetologist" and "I am glad YOU are hearing this, since I surely don't!"

I was thrilled when we came to the first series of shelters at what was known as Quarry Field, since the pace finally slowed down and Henry said this was the best place to see Copperheads. Sure enough, there were two gorgeous Copperheads curled up under the first shelter we flipped and they were right in front of Henry. Problem was, there were also four Ringneck snakes right in front of me, and, while I had eyes only for the Copperheads (and did not see the Ringnecks), Henry did exactly the opposite. Thus, I went for the Copperheads in front of Henry with my hook and Henry bent down to get the Ringnecks in front of me (thinking, I am sure, "who is this dummy who does not see snakes right in front of him?"). As we bounced off of each other, Henry stumbled forward, putting his foot right in front of the copperheads, one of which immediately struck his boot!. I could see the headline now: "Famed herpetologist killed by venomous snake; new grad student to blame."

Fortunately, the snake managed only to clip the front of Henry's boot, and we quickly captured both Copperheads and at least some of the Ringnecks. After flipping a few more shelters, we had a total of four Copperheads, three of which were marked individuals, one as long as nine years ago. I found this nothing short of amazing, having only recently read that high recapture rates were impossible for snakes, and said as much to Henry. He shook his head and said: "If I had just a few more fences and more shelters, I'd have a 100% recapture rate." I glanced at Henry, trying to decide if he was saying this in jest or if he was angling for a compliment. I quickly realized that neither of these were true; he genuinely felt that he had simply not worked hard enough and needed to do more to satisfy his own standards. What a great example for a new Ph.D student!

A few years later, I got to see a second example of Henry's genuine humility regarding his fieldwork when the noted lizard ecologist Laurie Vitt visited the Reservation. Knowing that Laurie was especially interested in lizards, Henry made sure to check the shelters where he knew Slender Glass Lizards could be found, and we quickly got several of them. When Laurie said something to the effect of "are you going to publish anything on these?" Henry indicated that the sample size was still too small for a solid publication. Laurie asked: "How many of them have you found?", thinking (I am sure) that the answer would be a hundred or so. Henry's response floored us: "About 1500 so far" he said rather casually. When we tried to convince Henry that 1500 glass lizards was nothing short of phenomenal and far more than anyone else had, he just shook his head and said he needed more data! By the way, Henry did publish a monograph on these lizards in 1989; the sample size was 2216 individuals captured 3353 times! (Fitch 1989).

In addition to doing field research with Henry, I was also lucky enough to be his TA for the last two courses he taught at KU, Vertebrate Natural History and Animals of Kansas. Both courses were combined lecture/field trip formats and my main role was driving students to and from the field sites and helping in the field any way that I could. Although

Henry's lectures were detailed and comprehensive, the fun part of both classes was the field trips. Students enjoyed trying to "challenge" Henry by bringing him whatever odd insect, snake skin, or mammal dropping they found, then having him act as a living version of Wikipedia and proceed to lecture them on everything that was known about the species under question. One of my favorite memories was when a student found a newly hatched Five-lined Skink and asked Henry how much the tiny lizard weighed. Henry held the lizard for a few seconds and then replied: "1.15 grams." The class immediately burst out laughing at the absurdly precise answer. So, the whole class walked over to the old, dilapidated building that Henry called his "lab" and we proceeded to weigh the skink on an old triple-beam balance. Sure enough: 1.15 grams! Somewhat awed, one of the students asked "How could you possibly know that?" Henry's response was typically low-key: "When you have processed over 5000 of something, you know their weights pretty well!"

Given Henry's low-key approach and humility, it would be easy to conclude that he was not competitive and that he would let his grad students get away with things. Neither conclusion would be true. I recall quite well the first time Henry came to my study site in northwestern Missouri where I was doing mark-recapture studies on snakes. After catching our first snake of the day, I marked it using scale-clipping (no PIT tags in those days) and proudly showed it to Henry. "Oh," he said, "I guess you don't want to be able to recognize this snake if you capture it again?" This was Henry's way of telling me I was not marking properly, and the message was delivered loud and clear. To this day when I scale clip snakes, I follow Henry's methods and can tell you, they work extremely well.

Henry's competitive nature may be illustrated by something only a select few got to experience, something called "Fitchian Basketball." Henry always had a grass/dirt basketball "court" set up outside his front door and during the spring of 1980, his current students got a taste of how competitive Henry Fitch could be at times. There were eight of us that day, three women (Nancy Zushlag [Henry's master's student], my wife Nadia, and Jim Knight's wife, Karin), and five men (Henry, myself, and three of Henry's other students, Larry Hunt, Luis Malaret, and Jim Knight). When the time came to play, Henry started explaining the "rules"; first, there were two hoops, one at 10 feet, the other at 8 feet. The 10-foot hoop was for the guys, the 8 foot hoop for the women. Next, there were odd but very specific rules about the men and women taking the ball out separately, whether the women could be guarded, and how the points were tallied. What we all found most amusing was how new rules suddenly appeared whenever someone scored against Henry's team. My personal favorite was "no jump shots from the corner," which just happened to be my best place to shoot from. Needless to say, we all spent more time laughing than we spent playing, as watching Henry morph into this competitive jock was something none of us had seen before.

Basketball finished, we then got to see a fine demonstration of Henry's character. Henry was due to retire that year and it fell to our group of graduate students to find an appropriate way to celebrate Henry's many achievements. With the help of Joseph Collins, Bill Duellman, and many others, we organized a symposium at the 1980 herp meetings in Milwaukee, with many of Henry's former students presenting papers. We also planned to publish a volume based on that symposium, which appeared in 1984. After lunch, we sprang all this on Henry, including a plaque made especially for the occasion. Henry was deeply moved (Virginia was in tears), but I could tell that while he was clearly touched, part of him was saying to himself: "I need to get out there and check the shelters…"

No discussion of Henry could possibly be complete without mentioning Virginia. Her pride in Henry's accomplishments and her irreplaceable role in his life cannot be overestimated. Watching her beam from ear to ear during our symposium honoring Henry in 1980 was a joy to watch. For me (and Nadia), Virginia was more like a grandmother than the wife of my major professor. From giving us furniture when we were starving grad students to giving our son his first tricycle, her warmth and devotion to Henry and his students was truly remarkable.

As I think of Henry now, I see him heading off to do another "round" at the Reservation. May he always have as many shelters to check as he could ever want and may his traps always have many marked snakes. When his morning rounds are over, he'll be headed back home, where Virginia has lunch waiting.

Natural History Observations of Henry Fitch

RAYMOND B. HUEY
Department of Biology (Box 351800), University of Washington
Seattle, Washington 98195-1800, USA
e-mail: hueyrb@u.washington.edu

The Second World Congress of Herpetology was held in Adelaide, Australia in 1994. One symposium was on the biology of snakes, and Henry Fitch was a presenter. For many in the audience, this was their first time to hear the legend in person. So as Henry walked to the podium, the audience's initial mood (or at least mine) was one of excitement, anticipation, and respect.

Henry gave an amazing talk. The theme was long-term (really long-term!) demographic trends of all of the snakes on the Kansas Natural History Reserve. The results were stunning but depressing: the density of essentially every species had declined over time.

The audience (largely snake buffs of the first order) quickly became somber. Adding to the poignancy of the moment, we all recognized that this grim result was being delivered by a kind and gentle man whose deep love for snakes and their natural history had inspired him to carry out a life-long study of these snakes. But the clear conclusion emerging from all of his immense work was that his beloved subjects were declining to extinction. Sometimes, life doesn't seem fair.

Either in his talk, or in the question period afterwards, Henry noted that a primary cause was a policy of suppressing fires on the Reserve: as a result, succession was unchecked, such that habitats on the reserve were increasingly forested and increasingly unfavorable to snakes.

Someone asked, "Why don't you light a fire?" Henry thought for a moment, and then replied quietly, "I can't do that." My distinct impression at the time was that he really did want to do just that, but ethically that he couldn't do so, given his position at the Reserve.

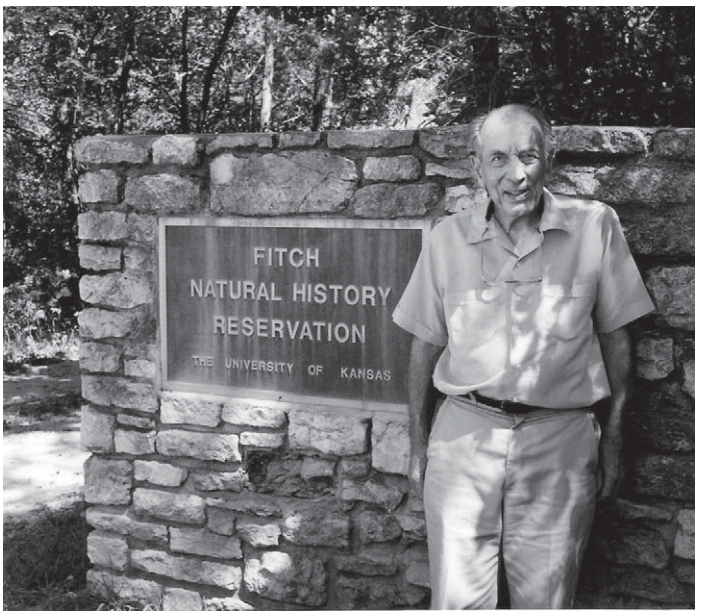
But I also remember distinctly feeling at the time that Henry was sending a subliminal message to us in the audience: "If you want to start a fire..."

For me Henry's talk was certainly among the most memorable ones of the entire Congress. Moreover its central lesson still haunts my thoughts. We should do science because we love the process, not because we need to love the results. Henry Fitch could not have loved the results of his work, but there's no doubt he loved the process.

Henry Fitch: The Twilight of an Incredible Career

GEORGE R. PISANI
Kansas Biological Survey, University of Kansas
2101 Constant Avenue, Lawrence, Kansas 66047, USA
e-mail: gpisani@ku.edu

I first met Henry Fitch in 1968, forty-one years ago, while visiting a friend in Lawrence. I'd read many of his papers in the course of my studies, and when I met him again in 1970 I was again impressed by two things beyond his vast store of knowledge. At age fifty-nine he could, while making a round in the field, walk the legs off many people far younger. And, for someone whose many papers had essentially established the field of snake ecology as we now know it, he was incredibly unassuming and reserved (except when playing the, ummm… *rules-modified*, basketball games that then were a Reservation feature event).



Many herpetologists accompanied this remarkable man into the field in the course of his long, distinguished career. It was my distinct privilege to be among them at various times, and to work with him during the final few years of that career. Our close professional relationship really began in the mid-1980s with our collaboration on Timber Rattlesnake telemetry. I built an effective (albeit awkwardly maneuverable) antenna. Using that and some transmitters (immense by current standards!) assembled by Dr. Tony Shirer and which Henry pushed gently down the throats of large rattlers, we spent a summer gathering movement data that retrospectively turned out more a learning experience about the technique than about the snakes. Henry assimilated all this, and nearly 20 years later, when we had far better equipment and far more background knowledge on the subtleties of using it, we were able to initiate an ongoing study of this species in northeast Kansas.

In 1987 Henry and I received funding from Oklahoma Dept. of Natural Resources to study rattlesnake roundups and their effects on the populations of Western Diamondback Rattlesnakes. It was no secret that Henry's long-term enthusiasm for rattlesnake study wasn't shared by his wife Virginia, perhaps out of recognition that his reflexes were slowing, as do everyone's with time, hampering the avoidance response essential for such work. It's one thing to dodge the feint of a 2-foot copperhead, but quite another to dodge the long strike of a 5-foot *Crotalus*. Virginia's reaction was subdued apprehension. But after some discussion we agreed to handle the captive snakes after cooling them, a reassuring model that Virginia accepted and which proved effective for safely gathering the morphological data we sought.

Henry's enthusiasm for field work and for learning all there was to learn about snake ecology never diminished, though by 2002 time plainly was having its inexorable effect of limiting bone and muscle. In these later years of his career I had retired, and so was able to help him make rounds in the field using one of the field station's "Gator" ATVs. I drove while Henry's gaze was fixed firmly on our destination of the day, wherever it happened to be. By 2003, he was gamely trying to maneuver using crutches on a local ledge that served as a Timber Rattlesnake den. I emphasized to him that I didn't plan to be remembered as the guy who brought him back from the field with a severe envenomation or a broken leg, and so he agreed (perhaps acquiesced is a more accurate term!) with a change of model— I'd do the rough and tumble stuff and he'd wait in the 6-wheeler to share in the results, and we'd collaborate on papers that of course required his incredible store of knowledge. Or if topography allowed, he'd hunt close to the 'Gator while I ventured further. That model worked well through the remainder of the time he was able to live independently on FNHR, and other persons, younger than either of us, pitched in to help Henry make productive rounds in the field safely. Notable among these are Scott Sharp (a high school teacher in a nearby district) and his family, and KU undergrads Mike Zerwekh, and Joey Brown.

As late as 2006, the "Henry and George team" (which I once pointed out to him had an average age of 79, a realization he greatly enjoyed) still made joint rounds, these in my Smooth Earth Snake study area not far from FNHR. This was a species he'd barely seen, with just 3 FNHR records. He was fascinated by the fact that the species was so close, yet he'd seen so few. When on our first trip into that area I caught the first of several we subsequently found in tall grass habitat, his reaction was to look at it intently and softly remark "Well, I'll be damned." I think it was the only time I heard him say that! I'm glad I sent him the final draft of the article summarizing that research. When I emailed it to his daughter Alice, his primary care-giver by then, I asked her to "tell Henry he has to stick around to see this in print." Planned publication was for December 2009. Alice read it to him and afterward told me how attentive he'd been and how he'd enjoyed learning about this elusive species.

On 8 September 2009, just a few months shy of his centennial birthday, Henry Sheldon Fitch passed away, leaving for science one of the most outstanding legacies of ecological study ever known. Best known for his extensive long-term study of the herpetofauna of what in 1948 was The University of Kansas Natural History Reservation (renamed in 1986 the Fitch Natural History Reservation [FNHR]), his published studies in animal ecology extending back to 1933 also include a wide range of birds, mammals and invertebrates, as well as the local successional flora of their habitats. Harry Greene, interviewed by the Lawrence Journal-World, accurately reflected on Henry's legacy by stating "It's not an exaggeration to say that Henry's the father of snake biology." His studies on the ecology and relations of these many species were refined through his extensive career to reflect his unique insights regarding the way they form communities of interacting organisms. All of us who continue to build on this legacy, and those who follow us and will do the same, owe a tremendous thanks to this modest man of great talent.

Ilya S. Darevsky (1924–2009): Discoverer of Parthenogenesis in Reptiles

KRAIG ADLER
Department of Neurobiology and Behavior, Cornell University
Ithaca, New York 14853–2702, USA
e-mail: kka4@cornell.edu

Ilya S. Darevsky, discoverer of natural parthenogenesis in reptiles and the leading herpetologist of his country for nearly half a century, died on 8 August 2009 in St. Petersburg at the age of 84. His death is a great loss to Russian herpetology and, as a measure of the greatly changed political situation in his country in recent years, it is also deeply felt by his many colleagues and friends throughout the world.

This change could hardly have been imagined at the time Darevsky was beginning his professional career in the 1950s. Correspondence between Soviet and Western herpetologists then was virtually nonexistent. (My own correspondence with Ilya began in 1963 when I was a first-year graduate student. His letters to me had clearly been opened and clumsily re-sealed. He later told me that all of my letters to him also had been opened, by the Soviet authorities.) Exchange visits in those times were all but impossible. (I first met Ilya at a conference in Budapest in 1981. As an indication of the realities faced by Soviet scientists even when travelling to fraternal socialist countries, there was a KGB agent accompanying the Soviet delegation at that meeting.)

As a result of this prior minimal contact, herpetologists in the United States who had noticed unusual sex ratios in species of teiid lizards and ambystomatid salamanders were initially unaware that Darevsky had already announced his fundamental discovery of natural parthenogenesis in a 3-page paper published in Moscow in 1958. Because this article was in Russian, the precedence of his discovery was not immediately recognized by American and other Western herpetologists. Only in 1966, when Darevsky authored a long review paper in English in the last issue of the *Journal of The Ohio Herpetological Society* (predecessor to SSAR's *Journal of Herpetology*), did the full scope and depth of his research on natural parthenogenesis in lizards become widely known in America.

The existence of apparently all-female populations of the Caucasian rock lizards (*Lacerta* [now *Darevskia*] *saxicola*) had been known in Armenia since at least 1914, but it was Darevsky who demonstrated that this was not a mere sampling artifact. In a preliminary paper in 1957, he reported the absence of males in many populations of this lizard in northern Armenia. Suspecting that they might reproduce parthenogenetically, he decided to check the sex ratios of newly hatched lizards to be certain that the absence of males in nature was due to a genetic mechanism and not to differential selection after hatching. Gravid females were collected and held in individual enclosures where they oviposited. Each clutch was incubated separately and the sex of each hatchling was determined by observing the presence of oviducts or hemipenes and by sectioning the gonads. All hatchlings were females (published in 1958). His techniques were not difficult ones even then; the hard part was having the idea in the first place.

Subsequently, Darevsky and his colleagues demonstrated the hybrid origin of the parthenogenetic forms of *Darevskia saxicola*, which he regarded as distinct species. As the years progressed he was able to establish the genetic nature of the parthenogenetic species, which he showed had arisen through interspecific hybridization, and he proceeded to study the genetic mechanisms and the molecular biology of clonal species. For his pioneering studies on parthenogenesis in reptiles he was awarded the prestigious Mechnikov Prize of the USSR Academy of Sciences in 1987. Later that same year he was elected a member of this venerable academy that was founded by Peter the Great in 1725. Darevsky thus became an academician, the highest honor accorded to a scientist by his country.

Ilya Sergeevich Darevsky was born in Kiev, Ukraine, in 1924, an only child who, as he once told me, was "crazy about herps" from his early youth. Before he could enter college, however, he was inducted into the Soviet Army in 1942 and served with distinction during World War II—the Great Patriotic War as it is called in Russia. After the war's end in 1945, he worked at Moscow Zoo and then studied zoology at Moscow State University (1948–1953) before joining the staff of the Zoological Institute of the Armenian SSR Academy of Sciences, located in Yerevan near the Turkish border. At the same time, he was working on his candidate's degree, the first-level postgraduate degree (C.Sc., 1957). His thesis was on the reptile fauna of Armenia and its zoogeographic analysis, which put him in the field in the ideal location to discover all-female populations and parthenogenesis in lacertids.

After a few more years in Yerevan, he was called to Leningrad in 1962 as curator of the Department of Herpetology at the Zoological Institute of the USSR Academy of Sciences, in succession to Sergius A. Chernov who had been his graduate supervisor. In Leningrad, Darevsky completed his second thesis, on the Caucasian rock lizards (D.Sc., 1967). In 1974, he became head of a combined Department of Ornithology and Herpetology, a post he held until 1996 when he was named a senior researcher in the department. He was succeeded as head by Natalia B. Ananjeva, his former student who was, in effect, his chief of staff for many years and who most ably ran the department during his many absences in the field or for other travel. From 1978, Darevsky was also a professor at Leningrad (now St. Petersburg) State University where he lectured on herpe-

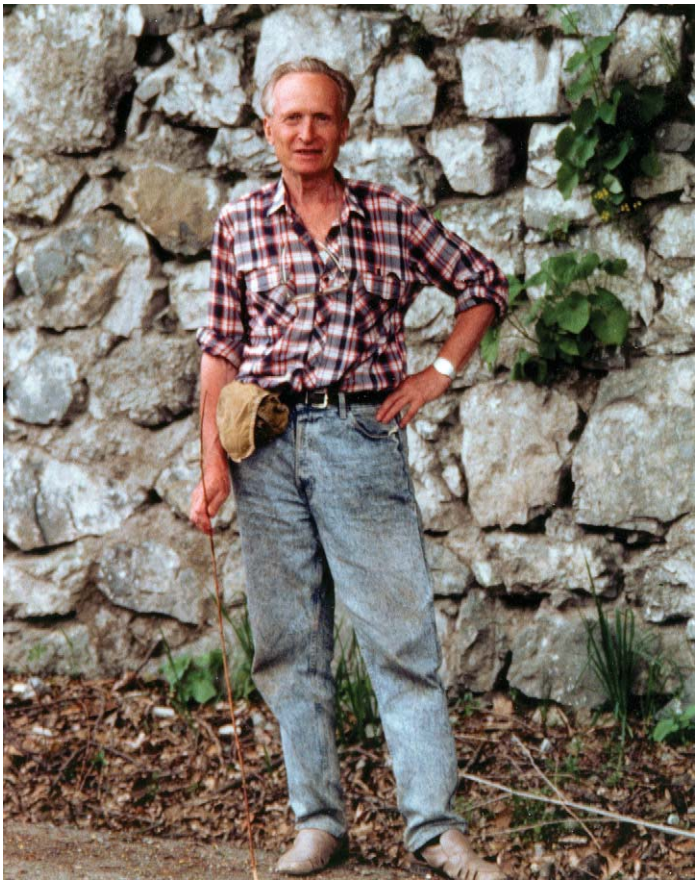
tology. Characteristically, he never forgot his colleagues in Armenia, where his epochal research began, and he regularly returned to lecture at Yerevan University.



Darevsky was married twice. His first wife, Irina G. Bei-Bienko, was an entomologist at the agricultural institute in Pushkin, a Leningrad suburb. She often assisted him in his research, both in the lab and the field. She died in 1978. They had one child, Alexander Ilyevich, a member of the Oriental Faculty at St. Petersburg University and a specialist on the Burmese language. Darevsky later married Vernata V. Grechko, a molecular biologist at the Institute of Molecular Biology of the Russian Academy of Sciences in Moscow. As Darevsky's work took on a molecular dimension, Grechko became actively involved and they co-authored several studies. She continues this line of research today including the associated fieldwork.

Darevsky became the natural leader of the large, but widely dispersed, herpetological community in the former Soviet Union. He was actively involved in sponsoring several of the All-Union Herpetological Conferences. These had been started by Paul V. Terentjev, Darevsky's colleague at Leningrad State University, as a means to promote the development of herpetology in the country. Terentjev organized the first two in 1964 and 1966, both held in Leningrad (abstracts published in *Herpetological Review* in 1967 and 1968). Darevsky, ably assisted by Ananjeva and other colleagues, ran the next four in Leningrad (1973, 1977), Ashkhabad (1981), and Tashkent (1985), and he edited a volume of proceedings for each one. Beginning in 1989, this organization became the Nikolsky Herpetological Society.

He was staunchly internationalist and promoted contacts with scientists in other countries, to the extent allowed by the Soviet authorities. It is difficult for many Westerners today to appreciate the extent to which herpetologists and other scientists in the former USSR and its associated socialist countries had their academic activities, to say nothing of their personal freedoms, affected by the caprice of communist bureaucrats. When Darevsky wanted to travel to the West in the 1980s, his requests were routinely turned down and usually without explanation, or at least a credible one.

Carl Gans and I attempted to bring him to the United States on several occasions, without success, but with his rise to academician status in 1987 it was finally possible. Even then, however, the Soviet authorities toyed with him as to the exact timing of his departure, which made the scheduling of his complex itinerary very difficult. When the authorities delayed his departure again and again, we had to revise our plans each time. As luck would have it, his eventual time of arrival could not have been more advantageous for him to meet American herpetologists, for he arrived just in time for the joint annual ASIH / HL / SSAR meeting in Ann Arbor, Michigan, in late June 1988 where he delivered the keynote address. This meeting was as memorable for him as it was for his audience.

A two-week tour followed, in order for him and his colleague, Natalia Ananjeva, to visit major museum collections and meet colleagues. Besides the University of Michigan, they visited the University of Kansas, Carnegie Museum (with an overnight at the museum's

On a field excursion in Armenia (1992), posing in front of what became known as "Darevsky's Wall" where he discovered the first unisexual lizards. The pole in his right hand was used to noose lizards. Photo by Robert W. Murphy.

Powdermill Nature Reserve), Cornell University, National Museum of Natural History (where they joined in Fourth of July celebrations on the National Mall), the Virginia countryside (for a full-day's field trip when, in his excitement, he caught a copperhead with his bare hands!), Academy of Natural Sciences and Philadelphia Zoo, American Museum of Natural History, and Harvard University. We had to make up for a lot of lost time! As he wrote on returning to Leningrad, "It's better one time to see than many times to hear."

Darevsky's visit to America was propitious also for his major involvement in planning the First World Congress of Herpetology that was to be held in Canterbury (UK) the next year. He was an active member of the executive committee of the congress secretariat. If Soviet herpetologists were to attend the congress, Darevsky was the key, for both the USSR and Soviet bloc countries, and he played his role masterfully, again with the important assist of Ananjeva. Because the Soviets would come as a delegation, they had to be selected and properly funded. It is safe to say that without Darevsky's leadership the congress would not have attracted delegates from as many countries as it did. (A total of 1,368 persons from 61 countries attended, still the largest and most nationally diverse herpetological meeting ever held.) As a personal gesture, Darevsky had commemorative metal badges made—complete with the congress's chameleon logo—which he passed out to the delegates. His role before, during, and after the congress was exemplary of his commitment to international science.

At home, Darevsky was equally devoted to being all-inclusive and open to new developments. His enthusiastic and ebullient personality attracted and inspired the best students, and his staff appreciated his democratic form of administration. He developed his department in Leningrad into his country's major center for the training of young herpetologists, both those who were his own students as well as those from other laboratories. They came from throughout the USSR and Vietnam.

Despite all his official duties for the institute and overseas, Darevsky continued to publish research papers on the reproductive biology and genetics of Caucasian rock lizards. He also authored or edited a large number of books. The most notable was an early summary of his work on rock lizards (1967; English edition 1978). He co-authored, with the conservationist Andrei G. Bannikov and others, the first color-illustrated field guide to the amphibians and reptiles of the Soviet Union (1971; second edition 1977). He wrote the herpetological volume, also with Bannikov, in a series on the animals of the world (1969; second edition 1985). With his department colleagues, Natalia Ananjeva, Leo Borkin, and Emilia I. Vorobjeva, he co-edited a number of volumes of collected papers on the herpetology of the USSR and Mongolia. Darevsky was also committed to amphibian and reptilian conservation and produced two books on the subject (one about the protected territories in the USSR, with Vladimir G. Kreven in 1987, and the other a color-illustrated review of rare and endangered amphibians and reptiles of the world, with Nikolai Orlov in 1988). Darevsky, together with Ananjeva, Borkin, and Orlov, produced a highly useful dictionary of the amphibians and reptiles of the world (1988), a checklist that is cross-indexed in five languages (Latin, Russian, English, German, and French). The same four authors wrote the herpetological volume in an encyclopedia of Russian animals (1998). His last book, written with five co-authors, was a colored atlas of the reptiles of North Eurasia (2004).

Darevsky's ability to conduct field research outside the Soviet Union was severely constrained, unless political reasons made it possible. In 1962, during a short period of Soviet influence in Indonesia, he spent two months in the Lesser Sunda islands as part of the Indonesian-Soviet Zoological Expedition to Komodo and surrounding islands. He worked in Iran in 1974 during a period when the USSR was seeking to improve its relations with Tehran. With the American military defeat in Vietnam in 1975, the new Socialist Republic of Vietnam strengthened its ties with the USSR and in 1982 Darevsky began a completely new line of research, on the amphibians and reptiles of Vietnam. This research was primarily done in collaboration with Nikolai Orlov and other colleagues in Leningrad. Darevsky, who was always an enthusiastic field naturalist, went to Vietnam on almost annual expeditions through 1995. His special interest was the herpetofauna of the offshore islands along the lengthy Vietnamese coast. He and his colleagues discovered many new species there and on the adjacent mainland and the high rate of new species discovery and description continues unabated to this day. Among them were several new all-female species of lizards. At the same time, he extended his work on the Caucasian rock lizards with a long series of genetic studies (molecular evolution of satellite DNA, allelic polymorphism of parthenogenetic populations, and nucleotide sequences of microsatellite loci, to name just a few of them).

Darevsky was seriously ill during his last few years and could not come to the Zoological Institute to work, but he was busy writing his memoirs, tentatively entitled "Herpetology and Life." His life and herpetology were indeed closely entwined, from his boyhood days in Ukraine to the dual pinnacles of Russian and international science. He was passionate about his animals, his country, about herpetology and biology, and about his wide circle of friends and colleagues. And he made a difference for them all.

Final Volume of the Series

BIOLOGY OF THE REPTILIA

Comprehensive Literature
of the Reptilia

Nearly 23,000 references with cross-referenced subject index in 1,400 pages (clothbound)

Pre-publication price to SSAR members: $95

e-mail: jbmurphy2@juno.com

The classic herpetological works produced in Paris around the time of the French Revolution were *Les animaux quadrupèdes ovipares, et les serpens* by Louis-Jean-Marie Daubenton, 1784; *Histoire naturelle des quadrupèdes ovipares et des serpens* by Count de Lacepède, 1788–1789; *Tableau encyclopédique et méthodique des trois règnes de la nature ... Erpétologie* and *Ophiologie* by abbé (Pierre Joseph) Bonnaterre, 1789, 1790; *Histoire naturelle, générale et particulière, des reptiles; ouvrage faisant suite à l'Histoire naturelle générale et particulière, composée par Leclerc de Buffon, et rédigée par C. S. Sonnini. / Par F. M. Daudin*, [1802–1803]; and *Histoire naturelle des reptiles: avec figures dessinées d'après nature / / par C. S. Sonnini et P. A. Latreille*, 1802. In all of these works, illustrated herps are not as naturalistic as those pictured later.

Dr. Ulrich Schuerer, Director of the Wuppertal Zoo in Germany, has alerted me to the existence of a rare publication "Nouvelle Ménagerie des Reptilies au Jardin des Plantes a Paris" by M. J. André, Architecte. Paris Librairie Générale de l'Architecture et des Travaux Publics. Ducher & Cie, 1880. This six-page paper describes the construction of the facility and is accompanied by 10 beautifully drawn plates showing the façade, floor plans, reptile enclosures, and illustrations of the visitor areas. Of particular interest are the drawings depicting the elaborate carpentry and ironwork, support columns for the ceiling, and the large crocodilian exhibit. These are not typical architectural drawings but rather works of art. National Zoological Park librarian Polly Lasker could only find one library listing this work—Bibliothéque Centrale du National d'Histoire Naturelle in Paris.

I have selected an array of interesting plates which reflect the essence of living amphibians and reptiles and the fine artwork created during this period. These are shown mostly in chronological order. All colored originals have been converted to a black-and-white format.

Acknowledgments.—The association of a menagerie of living animals as part of a museum of natural history is unique and provides an important model for cooperation between these entities. The remarkable educational, research and artistic scope in Paris for over 200 years, as described in the important contributions of Patrick David, Jean Lescure, and Michel Thireau, has led to a greater understanding of the proper role between a zoological garden and museum of natural history. I am grateful to these authors for their insight and input.

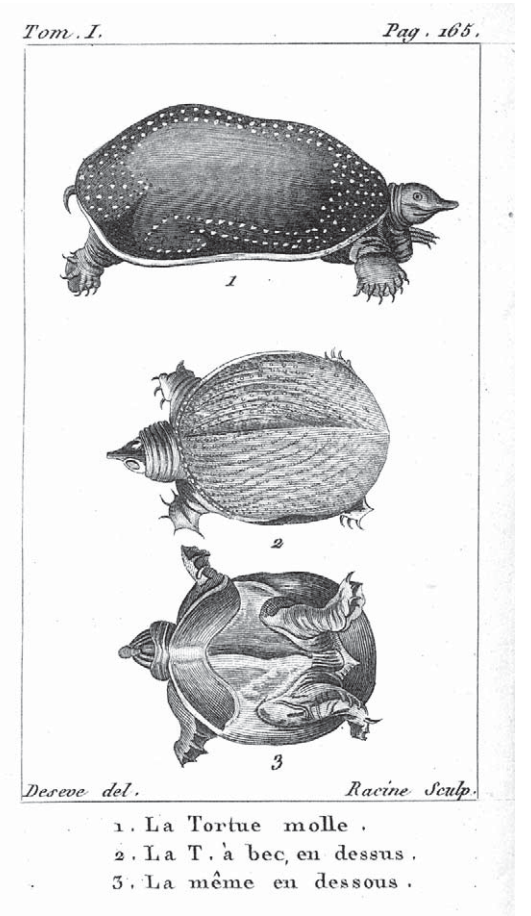
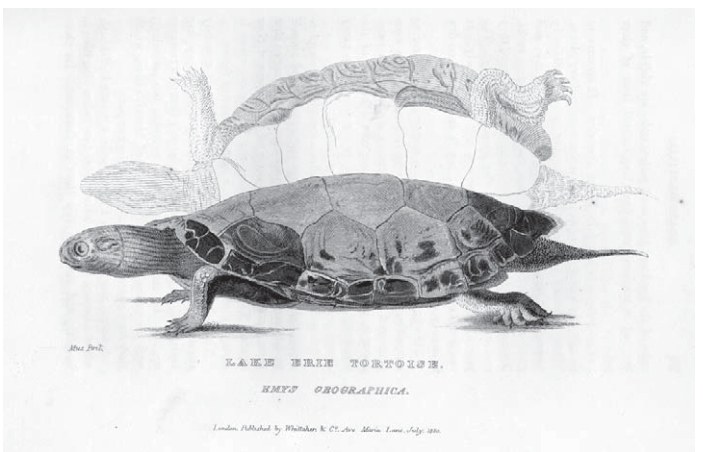
It is remarkable that the rare and elusive cave-dwelling European Olm (*Proteus anguinus*) was displayed at the Ménagerie in 1823. Illustration from Georges Buffon's *Natural History*.



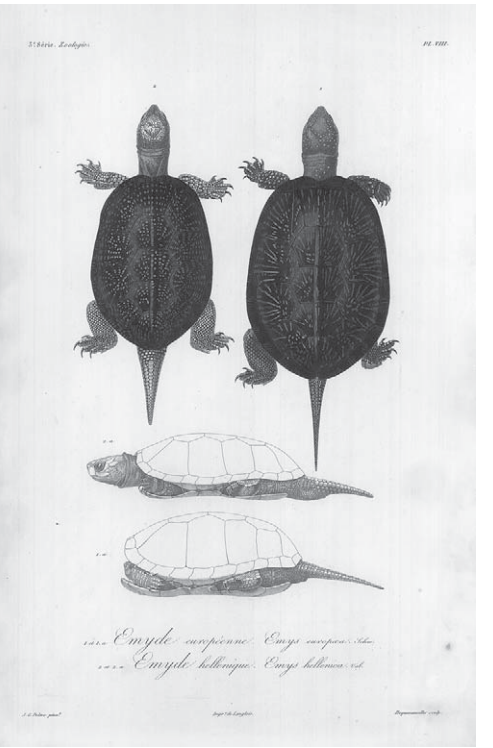
Louis Daubenton (1716–1800) was first director of the museum in 1793 and a colleague of Buffon. Most of the observations on foreign animals that were described by them in the fifteen first volumes of the Natural History were done at the menagerie. Daubenton's *Les animaux quadrupèdes ovipares, et les serpens* was not illustrated so the publisher commissioned Pierre-Joseph Bonnaterre (1751–1804) to oversee the production of the plates and write captions—Daubenton's work and Bonnaterre's *Erpétologie* and *Ophiologie* are often bound together. Shown here are rattlesnakes from Bonnaterre. Credit: Library of Roy McDiarmid.

Except for the aquatic genus *Typhlonectes*, caecilians are rarely kept in zoo collections, likely due to their secretive nature. Shown here is a Ringed Caecilian (*Siphonops annulata*) from *Dictionnaire universel d'histoire naturelle* by Alcide D'Orbigny.



Lovely drawings of Nile Crocodile, and Gavial from *Histoire naturelle des quadrupèdes ovipares et des serpens. Par M. le Comte de la Cepede*. Imprint: Hôtel de Thou, Paris, 1788–89. In the plates, herps are sometimes juxtaposed to humans or manmade objects such as formal gardens, buildings, temples, pyramids, and so on; this was part of the artist visual vocabulary of the time—it was not just random placement. Credit: Collections of Ernst Mayr Library, Museum of Comparative Zoology, Harvard University.

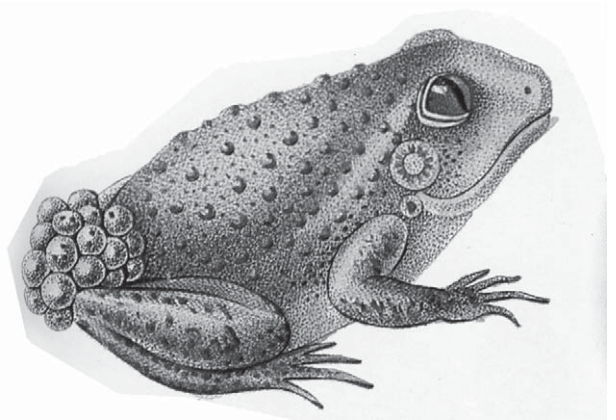
In 1801, Charles-Nicolas-Sigisbert Sonnini de Manoncourt (1751–1812) and Pierre-André Latreille (1762–1833) co-authored the four-volume *Histoire Naturelle des Reptiles*, a comprehensive work covering amphibians and reptiles worldwide. This work was included in Georges Buffon's great encyclopedia, an ambitious attempt to summarize all of natural history. Twenty-five years later, the book was reissued, followed by another edition four years after the second one — all three editions were offered with either 54 plain or hand-colored plates. Shown here from Tome 1 — La Tortue molle. Credit: Collections of the Ernst Mayr Library, Museum of Comparative Zoology, Harvard University.



René Primevère Lesson (1794–1849) clearly thought that painting animals from nature was important, as evidenced by his book title in 1832–1835? and the accuracy of its drawings. This illustration of Le Caméléon Madécasse (*Chamæleo madecasseus*, now *Calumma parsoni*) is from *Illustrations de zoologie, ou Recueil de figures d'animaux peintes d'après nature* (Zoological Illustrations, or Collection of Animal Figures Painted from Nature). Credit: Courtesy of Smithsonian Institution Libraries, Washington, DC.

Common Map Turtle (*Emys geographica*, now *Graptemys geographica*) from *The animal kingdom, arranged according to its organization, serving as a foundation for the natural history of animals, and an introduction to comparative anatomy. / With figures designed after nature: the Crustacea, Arachnides, & Insecta, by M. Latreille. Translated from the latest French ed. With additional notes, and illustrated by nearly 500 additional plates* by Baron Georges Cuvier, 1834–37. G. Henderson, London.

Credit: Collections of Ernst Mayr Library, Museum of Comparative Zoology, Harvard University.



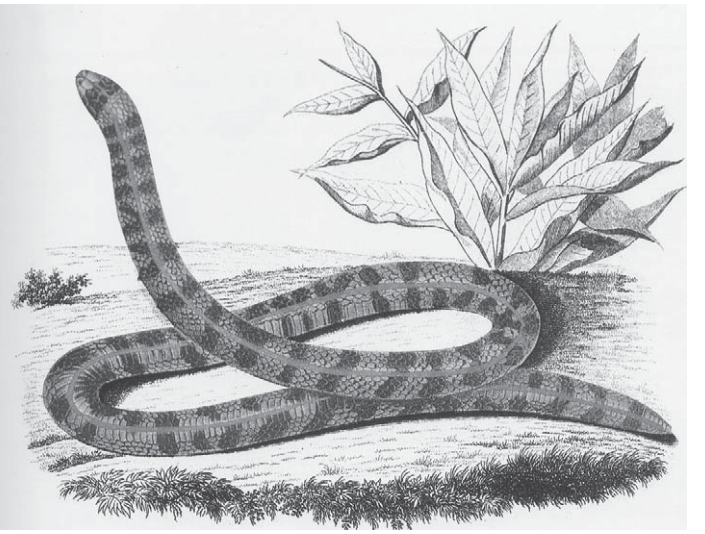
European Pond Turtle (*Emys orbicularis*) from *Expédition scientifique de Morée (1831–1838). Expédition scientifique de Morée. Section des sciences physiques. Zoologie: sect. 1. Des animaux vertébrés*. Imprint: F.G. Levrault, Paris, etc., 1832 [–1836]. This 3 volume set includes contributions by Étienne Geoffroy Saint- Hilaire (1772–1844) and his son Isidore Geoffrey Saint-Hilaire (1805–1861). The elder was the founder of the Ménagerie during the French Revolution and was the director for more than four decades until replaced by his son in 1838. The section on reptiles and fishes was written by G. Bibron and Jean Baptiste George Marie Bory de Saint-Vincent (1778–1846).

The most famous herpetological work by the Geoffroy father and son combination was the amphibian and reptile section in *Description de l'Egypte*, published in 1827 with a second edition two years later. The enormous plates are stunning. Two are particularly impressive: Nile Softshell Turtle and full-sized cobra in a defensive posture with hood extended.

Credit: Collections of Ernst Mayr Library, Museum of Comparative Zoology, Harvard University.

Jean-Théodore Cocteau (1798–1838) worked under Constant Duméril at the museum. His most important herpetological work was the section in Ramón de la Sagra's *Histoire ... de I'Ile de Cuba*, covering turtles, crocodiles, and lizards; Gabriel Bibron wrote the section on snakes and frogs. Pictured here is the False Chameleon (*Chamaeleolis chamaeleonides*, now *Anolis chamaeleonides*), clearly one of the most spectacular herpetological drawings. Credit: Library of Roy McDiarmid.

Midwife Toad (*Alytes obstetricans*) from *Zoologie classique, ou, Histoire naturelle du règne animal* by Félix-Archimède Pouchet (1800–1872) in 1841. Paris, Roret.



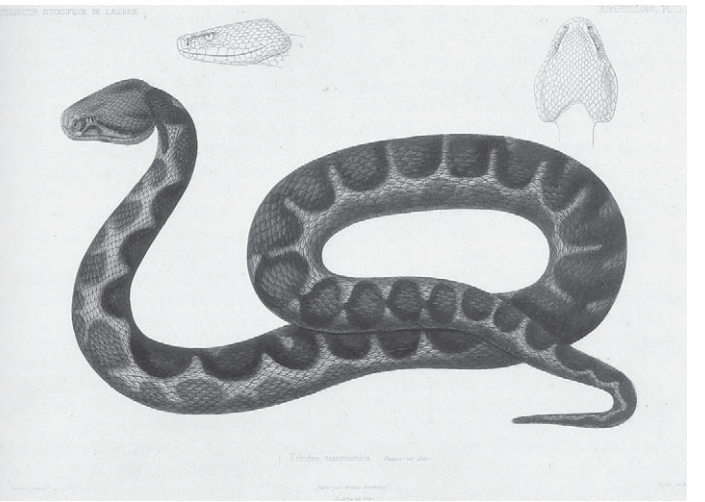


Illustration of Coral Pipe Snake (*Anilius scytale*) from *Dictionnaire universel d'histoire naturelle. Atlas. Zoologie. Reptiles, Poissons et Insectes* by Alcide D'Orbigny. Credit: Library of Roy McDiarmid.

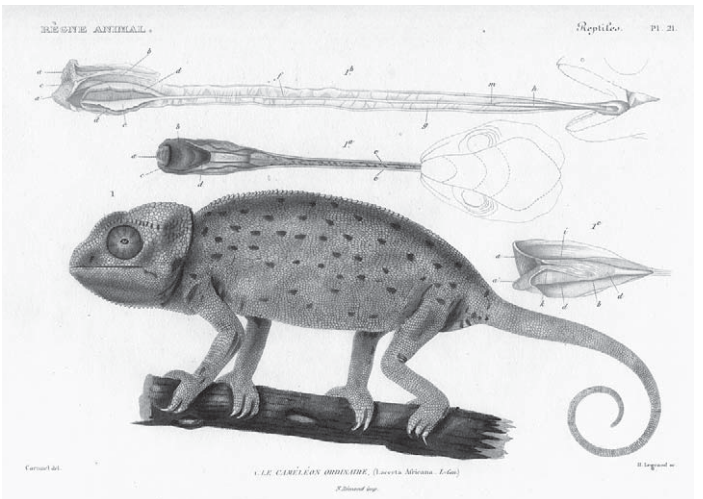
Nile Softshell Turtle (*Trionyx triunguis*) from *Zoologie classique, ou, Histoire naturelle du règne animal* by Félix-Archimède Pouchet.

Alphonse Guichenot's (1809–1876) father was a gardener at the menagerie. Hired as a junior naturalist at the museum, he prepared specimens for examination to be used in the nine volume *Erpétologie générale*. Guichenot published a number of herpetological works on his own, including the one covering the Algerian expedition of 1840–1842; he was a participant in that enterprise. This Moorish Viper (*Echidna mauritanica*, now *Macrovipera mauritanica*) is pictured in *Histoire naturelle des reptiles et des poissons*, 1850.



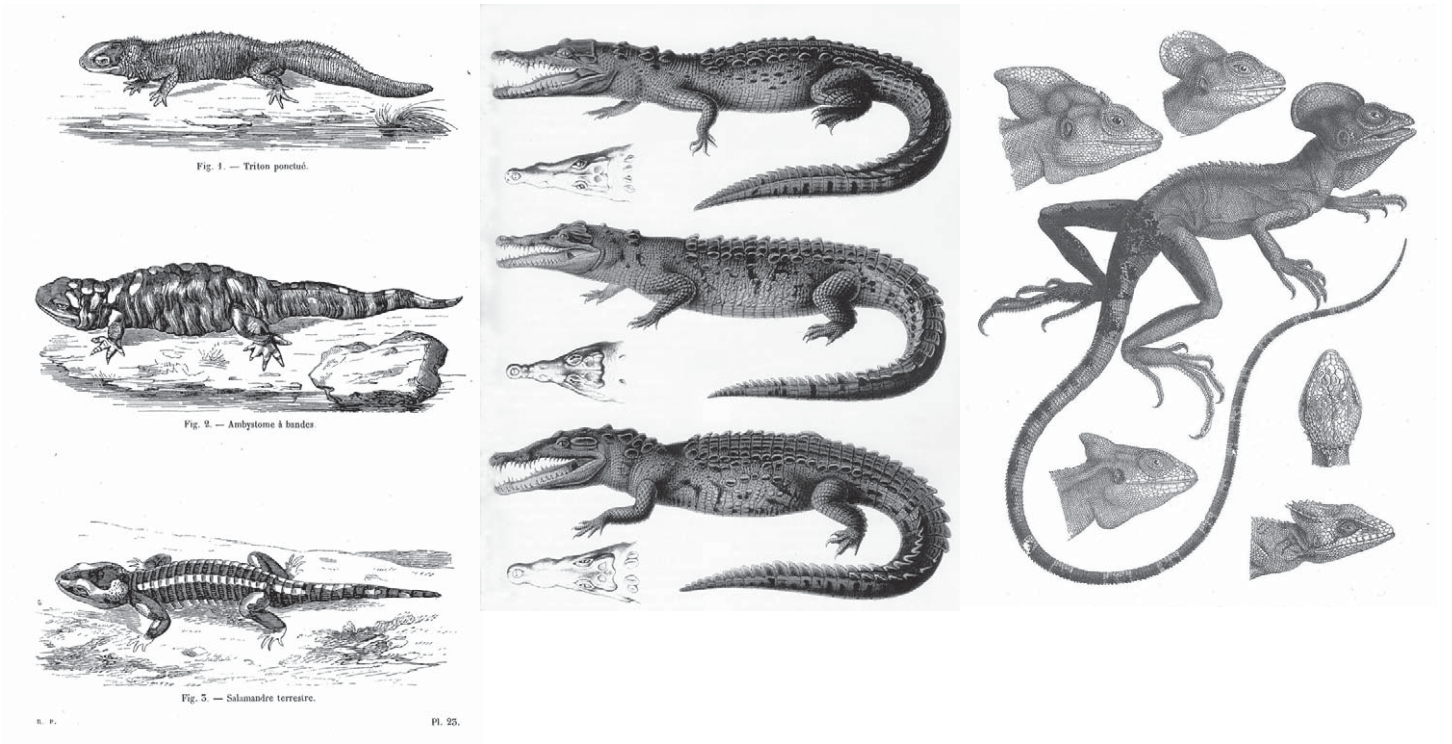


Illustration of African Chameleon (*Lacerta africana*, now *Chamaeleo africanus*) from Georges-Louis Duvernoy's (1777–1855) Disciple edition of the Reptiles volume in *La Règne Animal par Georges Cuvier* in 1842. Many prominent herpetologists who were disciples (students) of the late Cuvier are listed on the title page. Credit: Courtesy of Kraig Adler.

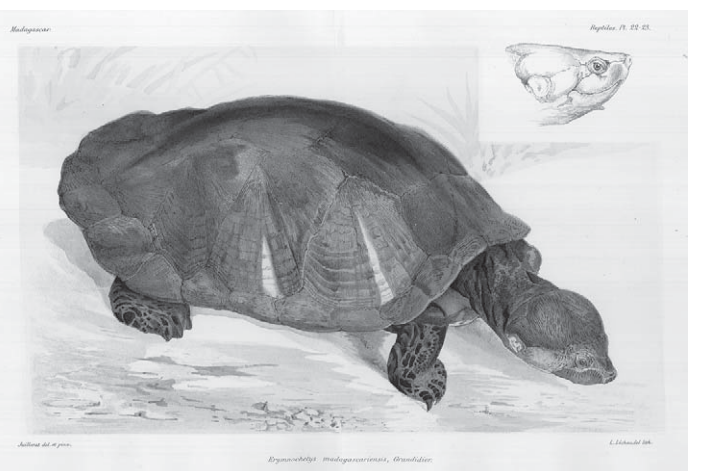

Left. Illustration of Newt and Salamanders from volume 3 of *Encyclopédie d'histoire naturelle; ou, traité complet de cette science d'après les travaux des naturalistes les plus éminents de tous les pays et de toutes les époques: Buffon, Daubenton, Lacépède, G. Cuvier, F. Cuvier, Geoffroy Saint-Hilaire, Latreille, De Jussieu, Brongniart, etc. / Ouvrage résumant découvertes modernes jusqu'à nos jours, par le Dr. Chenu ... Éd. Firmin-Didot et cie* by Jean Charles Chenu (1808–1879), 1856. Imprint: Paris, E. Girard et A. Boitte, [186-?–187-?]. Center. Marie Firmin Bocourt (1819–1904) worked closely with Aug. Duméril on the monumental *Études sur les Reptiles*, one of the seventeen parts of *Mission Scientifique au Mexique et dans L'Amérique Centrale*. The total number of lithographs drawn by Bocourt for this book was 92 and some of them included as many as 50 separate drawings. Shown here from top to bottom are *Crocodilus americanus*, *C. lewyanus*, and *C. mexicanus*. All are now recognized as the American Crocodile (*Crocodylus acutus*). Right. Illustration of Basilisk (*Basiliscus*) and Casqueheaded (*Laemanctus*) Lizards from Aug. Duméril's *Description des reptiles nouveaux ou imparfaitement connus de la collection du Muséum d'histoire naturelle et remarques sur la classification et les caractères des reptiles.* [Arch. Mus. Paris, vol. 8:437–588 (1856)]. These are some of the best plates in herpetology. Credit: Courtesy of Polly Lasker, Smithsonian Institution Libraries, Washington, DC.

Emerald Tree Boa (now *Corallus caninus*) from *Histoire naturelle de Lacépède, comprenant les cétacés, les quadrupèdes ovipares, les serpents et les poissons* by Bernard Germain Etienne de La Ville sur Illon La Cépède (Count de Lacepède**)** in 1860.

Imprint: Paris, Furne, 1860.

One of the rarest species on the planet is nearly extinct: Madagascan Big-Headed Turtle (*Erymnochelys madagascariensis*) shown here from *Histoire physique, naturelle, et politique de Madagascar* in 1910. This book by Léon Vaillant (1834–1914) and Guillaume Grandidier (1873–1957) has spectacular plates of crocodilians and chelonians fashioned by several different artists. Credit: Collections of the Ernst Mayr Library, Museum of Comparative Zoology, Harvard University.

Predicting peak sea turtle nesting can help turtle conservation groups improve their monitoring strategies by planning intensified beach monitoring during the predicted peak nesting periods (Garcia et al. 2003). Currently, few of the factors controlling the emergence of sea turtles on land to lay eggs are understood, and it is unclear whether these factors are consistent among all sea turtle species. Bustard (1979), working on the Atlantic coast, suggested that nesting cycles of sea turtles might be associated with high tides where tidal cycles are pronounced. Frazer (1983) concurred, but demonstrated that this relationship did not hold for Atlantic beaches with similar slopes between high and low tide lines for *Caretta caretta* (Loggerhead). Girondot and Fretey (1996), studying *Dermochelys coriacea* (Leatherback) in French Guiana, also reported peak nesting cycles during high tides associated with spring tides (e.g., during the full and new moon). However, Bernardo and Plotkin (2007) suggested that *Lepidochelys olivacea* (Olive Ridley) nesting cycles in the eastern Pacific likely coincided with the third quarter moon, but admitted that it was unclear how lunar stages related to *L. olivacea* nesting.

Here we contribute to the understanding of *L. olivacea* nesting by confirming periodicity of nesting with lunar cycles, with an inverse relationship between *L. olivacea* nesting abundance and lunar illumination. Our results have both economic and environmental implications because they allow researchers and survey organizers to better predict the likelihood of encountering nesting turtles by calculating the fraction of the moon's visible disk illuminated by the sun. Such predictive power contributes to resource allocation strategies that can improve sea turtle monitoring programs, as well as our understanding of *L. olivacea* nesting behavior in relation to the moon's gravitational effects on tides and actual light (reflected from the sun) available on the beach.

Materials and Methods.—Our study area was Playa Teopa, located on the Pacific coast of Mexico in Jalisco State, part of an area commonly referred to as the Costa Alegre. Playa Teopa is 13 km south of the town of Chamela (19.5°N, 105.1°W). During 2000–2002, trained local volunteers and staff of the Teopa Beach Monitoring Project scanned the beach nightly (from midnight to sunrise) for nesting turtles from mid-July to early December and recorded standard monitoring information such as date, time, nest number and position, and turtle species. In prior years (1986–1992, 1994, 1997) scans were conducted on a less frequent basis. Playa Teopa is ca. 3 km long, undeveloped, and illuminated by celestial light only.

Lunar illumination data were obtained by entering nesting dates into the "Fraction of the Moon Illuminated" astronomical application under *Data Services* at the US Naval Observatory website (http://aa.usno.navy.mil), and recorded as 0 (= 0% illumination) through 100 (= 100% illumination). Although no climatic information (e.g., cloud cover) was recorded directly by observers as part of the Playa Teopa nesting surveys, data for temperature (degrees F), rainfall (inches), and visibility (km) were obtained for the nearby Playa de Oro weather station (19.1°N, 104.6°W) from the NOAA National Climatic Data Center website (http://www.ncdc.noaa.gov/oa/climate/climatedata.html) and incorporated into the dataset. Correlation, linear regression, and ANOVA were used to examine the effects of lunar illumination, a lag of nesting count, temperature, and visibility on nightly turtle nesting counts (rainfall was recorded in the Playa del Oro data for less than 5% of our nesting survey dates, and hence was not included). Statistical analyses were conducted using SAS Version 9.1 for Windows (2003, SAS Institute Inc., Cary, North Carolina).

Results and Discussion. —A total of 1925 nesting observations were recorded for *Lepidochelys olivacea* during this study. The majority of observations (N = 1237) were made during 2000–2002, the years of most intensive and consistent sampling; another 688 observations were made during prior years (1986–1992, 1994, 1997). The peak nesting period occurred from August to October (N = 1781 observations; 93% of total). This peak is consistent with other published reports for *L. olivacea* on this coast (Garcia et al. 2003). Statistical analysis focused on these three peak months. Spearman Rank correlation tests revealed a negative correlation between peak turtle nesting count and lunar illumination in 8 of the 12 study years, two of these being significantly negative (Table 1). Qualitatively similar results were obtained by performing linear regressions, by year, of nesting events against lunar illumination, lag, temperature, and/or visibility (Table 1), although lunar illumination was not significant in these analyses. In an attempt to increase power by combining data for the three well-sampled years 2000–2002, an ANOVA was conducted using all variables, with lunar illumination grouped into classes (1 = 0–19%, 2 = 20–39%, 3 = 40–59%, 4 = 60–79%, 5 = 80–100%). Lunar illumination, lag, and year were significant effects in this model (see Table 2; excluding temperature and visibility yielded comparable results).

These analyses indicate a modest inverse relationship between nesting counts and lunar illumination for *L. olivacea* at the Playa Teopa study site, and conflicts with the suggestion that peak nesting cycles occur during the third quarter moon for this species (Bernardo and Plotkin 2007). In fact, our data suggest that the best time to encounter nesting turtles is surrounding the dark period of the moon, where we recorded the greatest number of nesting events for each year surveyed. The new moon cycle is also consistent with the reported inter-nesting period for *L. olivacea* (e.g., approximately 28

TABLE 1. Relationship between *Lepidochelys olivacea* peak nesting counts and lunar illumination at Playa Teopa, as shown by non-parametric correlation and linear regression. N = number of sampling dates. Model A incorporates lunar illumination and lag of nightly nesting counts as dependent variables; Model B also incorporates temperature and visibility. Coefficients significant at p < 0.5 given in bold.

Year	N	Spearman R	Regression (Model A)	Regression (Model B)
1986	12	-0.33	-1.27	-0.62
1987	45	0.12	0.12	0.11
1988	23	0.11	0.19	0.62
1989	34	-0.20	-0.12	-0.12
1990	30	-0.04	0.08	0.09
1991	25	**-0.46**	-0.48	-0.27
1992	30	0.00	0.19	0.06
1994	30	0.10	0.02	0.12
1997	35	-0.06	-0.01	0.05
2000	85	**-0.19**	-0.32	-0.35
2001	90	-0.10	-0.10	-0.08
2002	92	-0.16	-0.20	-0.23

days), which is longer than most sea turtle species that have been examined (Rostal 2007). Such a pattern of nesting is not unique for turtles. A peak nesting cycle for the aquatic turtle *Podocnemis erythrocephala* has also been reported during the dark phase of the moon (Batistella and Vogt 2008).

Frazer (1983) noted that the advantage to nesting during high tide was a shorter crawl distance between water and nest, thus reducing the time of exposure to predators—darkness can also contribute to a decrease in the visual recognition of turtles by predators. Nesting during the new moon period offers the opportunity for high tides due to the centrifugal force caused by the earth's rotation. Another advantage of nesting during the period of the new moon may be an increase in prey availability to turtles post-nesting. For example, Lang et al. (2005) reported that the availability of katydid prey during the new moon period influenced foraging by their bat predators, resulting in a greater activity of both during the dark phase of the moon. Lunar cycles are also reportedly synchronized with emergence patterns in some invertebrates (Saigusa and Oishi 2000). Wild *L. olivacea* has been reported to feed primarily on crabs (Shaver and Wibbels 2007), which are most active, and forage, in darkness. Playa Teopa is not known to attract *arribadas*, thus the *L. olivacea* females we observed are likely solitary nesters. Solitary nesters are known to use multiple beaches hundreds of kilometers apart during a nesting season (Morreale et al. 2007). Therefore, it seems reasonable to suggest that *L. olivacea* prefers to emerge during the high tide of the new moon to lay eggs, because shorter crawls combined with the availability of prey may improve the likelihood of successful nesting, and subsequent feeding that can help support such travel.

TABLE 2. Analysis of variance of *Lepidochelys olivacea* peak nesting counts at Playa Teopa against lunar illumination, year, lag of nightly nesting counts, visibility and temperature. See text for descriptions of dependent variables. Significant model effects are given in bold.

Effect	df	F	p
Lunar Illumination	4	4.22	**0.002**
Year	2	4.25	**0.015**
Year*Lunar Illumination	8	0.77	0.632
Lag(Nesting Count)	1	30.30	**0.000**
Visibility	1	1.58	0.210
Temperature	1	2.40	0.122
Error	358		

We encourage other researchers to reassess their long-term nest conservation data to test whether the lunar phase results reported here are specific to Playa Teopa and *L. olivacea*, or may be more broadly applicable to sea turtles in general.

Acknowledgements.—This project was funded by a CSU-AAUP grant to T. Pinou. We thank the Centro de Proteccion y Concervacion de Tortugas Marinas, Playa Teopa for the support provided to A. Peña de Niz to monitor nesting, and the Yale Environmental Sciences Fellowship Program for the support provided to Yale students to travel to Mexico and help monitor nesting. We also thank L. Demaree for her earlier assistance in this project, and D. Briggs (Yale University) and two anonymous referees for helpful comments on the manuscript.

The Blanding's Turtle (*Emydoidea blandingii)* is known to nest considerable distances from water (Congdon et al. 1983; Ross and Anderson 1990), and it has been generally assumed that hatchlings travel to wetlands in order to survive their first winter in aquatic environments following emergence in late summer or early fall. The behavior of neonate Blanding's Turtles has been studied in Massachusetts (Butler and Graham 1993, 1995), Nova Scotia (Standing et al. 1997), and Minnesota (Refsnider 2005). All three studies tracked neonates for varying time periods, but not through the first winter. Butler and Graham (1993, 1995) believed emerged hatchlings sought standing water. Standing et al. (1997) tracked hatchlings for a maximum of 11 days and found overall the newly emerged hatchlings avoided water. Refsnider (2005) tracked three hatchlings to burrows in moist microhabitat and monitored hatchlings until either the 21-day battery expired or the hatchling was predated. From our previous years of monitoring *Emydoidea* nests, we have never found hatchlings to successfully overwinter in their nests. In previous years, hatchlings emerged by October or, as in 2004 with unseasonably cool temperatures, hatchlings that did not emerge in the fall were found dead within the nest chamber the following spring (pers. obs.; Refsnider 2005).

This study was part of a larger ecological study of Blanding's Turtles conducted by Three Rivers Park District (Park District) within 2,600-acre Crow-Hassan Park Reserve, northwestern Hennepin County, Minnesota. This study attempted to estimate numbers of adult and subadult turtles and to identify and protect nesting habitat. From 1994–2005, Blanding's Turtle nests located on road shoulders or in the middle of gravel roads were deemed at-risk from road traffic and predation by mammals and were salvaged for artificial incubation at 29°C. After hatching and yolk sacs were absorbed, hatchlings were released into the water at the edge of the wetland closest to the original nest location. Since previous research did not identify hatchling wintering locations, it was unknown if the release sites were appropriate for the hatchlings. This study was initiated to identify hatchling overwintering microhabitat, to assess predation while hatchlings were moving to overwintering sites, and determine overwinter survival at these sites.

Methods.—To determine hatchling survival and microhabitat use, newly emerged hatchling Blanding's Turtles were radio tracked in 2005 and 2006 to what were presumed to be overwintering sites. Seven hatchlings from two field nests in 2005 and seven hatchlings from two field nests in 2006 (including one nest that had been reburied ca 15 m from its original location) were radio tracked. Wire cages were placed over nests to trap hatchlings as they emerged; cages were checked daily. Transmitters weighing 0.48 g (Holohil Systems, Ltd., model BD-2N, battery life of 21–24 days) were affixed with a few drops of 5-minute epoxy on the 2nd and 3rd vertebral carapacial scutes of the largest hatchlings (37–39 mm maximum carapace length) (Fig. 1). Refsnider (2005) working with hatchlings in the Park District with the same transmitters determined the transmitters weighed a maximum of 5.1% of the hatchling's weight. Hatchlings were then released back at the nest sites within 24–48 h of emergence. Transmitters were replaced on seven of the hatchlings after 21–24 days; following replacement hatchlings were then released at the point of capture. Transmitters popped off easily with no apparent injury to the scutes.

Hatchlings were tracked (ATS, Inc. FM100 receiver; 3-element Yagi antenna) daily and were located within 30 cm of actual locations. Locations were flagged and GPS locations were taken with a Garmin 72. Visual observations of the hatchlings were obtained most days, with some exceptions resulting from dense vegetation and a desire not to disturb the animals. Monitoring was sufficient to determine general condition of the hatchling, its activity, condition of the transmitter, and type of habitat. Once the hatchlings had not moved in 2–3 weeks and temperatures dropped to near 0°C at night we assumed they had reached their wintering locations. At that point we caged them to prevent the hatchlings from escaping in spring. Wire cages were 0.6 m in height and 0.6 m in diameter and covered with 1.27 cm hardware cloth attached to 2.54 cm poultry wire and were secured in the ground with sod stakes. None of the caged locations were located in water at the time of caging. The cages were checked every 2 days beginning the following April for appearance of the hatchlings and to determine if any of the hatchlings survived.

Results.—In 2005, seven hatchlings (1930–1933;1938–1940) from two caged nests were tracked for varying periods of time (Table 1). Three hatchlings that were tracked for a total of 42–48 days to what appeared to be overwintering locations were in close proximity to each other. Each of these hatchlings was captured once to replace its radio transmitter. Although the monitoring period continued until batteries expired, no significant change in location was detected after an initial 5–6 days of travel from the nest.

FIG. 1. Hatchling *Emydoidea blandingii* with epoxied radio transmitter.

The hatchlings moved 350–487 m from the nest site. Two of the hatchlings burrowed out of sight into damp leaf litter in a dry drainage gully. A non-radioed hatchling, origin unknown, was also found in this same gully. The third radioed hatchling stopped ca. 15 m north of the gully, on higher ground within a grove of Gray Dogwood (*Cornus racemosa*). It stayed on the surface of the ground for several weeks. None of the three hatchlings were disturbed to remove the transmitters. Their locations were caged in late October, after no movement was detected for several weeks and air temperatures dropped to freezing at night.

Three other hatchlings from the second nest were tracked from 21–24 days into heavy vegetation of sedges (*Carex* spp.) and Reed Canary Grass (*Phalaris arundinacea*) at the edges of three different small, shallow pothole wetlands (<0.5 acres) (Table 1). Since we did not have enough replacement transmitters the transmitters were removed just prior to end of battery life. At the time of transmitter removal, none of the hatchlings had been observed to enter the water of the wetland. Although daytime ambient air temperature was often greater than 21°C and the animals appeared alert on the surface, the hatchlings made no significant change of location once they reached the wetland edge. It is not known in what microhabitat these hatchlings overwintered, since they were still on the surface when the transmitters were removed. However, based on the behavior of the three hatchlings monitored for 42–48 days, it was assumed that these hatchlings had also stopped movement in wintering locations. A fourth hatchling from the second nest was not recaptured prior to its transmitter expiring, but this hatchling traveled 743 m (cumulative daily straight-line distance) in approximately 10 days and was

TABLE 1. Summary of radiotracked *Emydoidea blandingii* hatchling movement from nests 2005–2006.

	Hatchling ID	Emergence date	# Days monitored	Overwinter date (caged)	Cumulative distance (m)	Overwintering site description	Emergence date/fate
2005							
Nest 1	1930	4 Sept 05	42	24 Oct 05	350	15 m upland from wooded gully	Alive in cage 13 Apr 2006
	1931	4 Sept 05	48	24 Oct 05	487	Damp leaf litter in wooded gully	Dead in cage in flooded leaf litter April 2006
	1932	4 Sept 05	48	24 Oct 05	363	Damp leaf litter in wooded gully	Fate unknown, hatchling not relocated
	1933	4 Sept 05	24	N/A	743	Last observed edge of pothole	Fate unknown, transmitter failed
Nest 2	1938	13 Sept 05	21	N/A	488	Last observed on vegetation in pothole	Transmitter removed 4 Oct 05
	1939	13 Sept 05	21	N/A	406	Last observed at edge of pothole	Transmitter removed 4 Oct 05
	1940	13 Sept 05	21	N/A	233	Last observed at edge of pothole	Transmitter removed 4 Oct 05
2006							
Nest 1	1945	25 Aug 06	6	N/A	316	N/A	Transmitter found without hatchling
	1946	25 Aug 06	48	11 Oct 06	346	Burrowed in damp organic soil under *Phalaris*, 5 m from edge of pothole	Hatchling found alive within cage 9 Apr 07
Nest 2	1947	5 Sept 06	42	17 Oct 06	340	Burrowed in damp soil beneath *Phalaris*, 3 m from edge of pothole	Fate unknown, hatchling not relocated in cage
	1948	5 Sept 06	43	17 Oct 06	543	Burrowed under mound of *Phalaris* 0.6 m from edge of 28-acre lake	Fate unknown, hatchling not relocated in cage
	1949	5 Sept 06	14	N/A	412	N/A	Found dead in aquatic vegetation at edge of pothole
	1950	5 Sept 06	12	N/A	378	N/A	Transmitter found without hatchling
	1951	5 Sept 06	42	17 Oct 06	253	6 m from pothole, under prairie grasses within tree saplings	Found dead in 12 cm of water in cage 09 Apr 07

last observed in ca 2 cm of water within *Phalaris arundinacea* at the edge of a shallow wetland adjacent to a woodlot.

Beginning in the first week of April 2006, cages were checked frequently for appearance of the hatchlings. The two cages in the ditch were flooded by the 2nd week in April when water started flowing through the ditch. One hatchling was not relocated within its cage, but the cage had shifted due to frost, leaving gaps at the base. After searching through water and wet leaf litter, the second hatchling was found dead amidst the leaf litter in its cage, which had become flooded about 12 cm deep by fast moving spring snow melt. It could not be determined when the hatchling died or how, but there were floating sticks and vegetation within the cage and over 45cm of airspace above water. The third radioed hatchling that had been caged on the higher ground within the grove of saplings was found moving above ground within the cage on 13 April 2006. The hatchling appeared to have come out of a ca 5 cm burrow-like depression. The hatchling had survived a winter of frequently 0 mm of snow cover with < 5 cm leaf litter and air temperatures of –25.6°C for several days in February.

In 2006, seven hatchlings (1945–1951) were initially fitted with transmitters (Table 1). Two hatchlings were lost because of detachment of their glue-on transmitters. A third hatchling was found dead 14 days after release. It was intact with no sign of physical injury, buried within a thick vegetation mat on the shore of a pothole. This was the only mortality documented for radioed hatchlings during the active season in the 2 years of study.

Four other hatchlings were tracked to what were presumed to be overwintering locations. They were tracked for 42–48 days before their individual locations were caged. Although three of the hatchlings entered shallow water for varying short periods, each later left the water. Each hatchling ended up close to, but not in, the water of a wetland or lake. The hatchlings were estimated to move between 253–543 m. All long distance movement (> 6 m) ceased after 9–26 days. Each hatchling was caged in mid-October. Prior to caging, the radio of one hatchling was removed because the hatchling's carapace was visible from just below the surface of the soil and the hatchling could be quickly retrieved for transmitter removal and returned to its burrow. However, since the other hatchlings had burrowed out of sight, they were not disturbed for transmitter removal.

Hatchlings could not be found the following spring (April 2007) in two of the cages, but these cages had gaps at the base from freezing and thawing. One hatchling whose transmitter had been removed was found intact but dead within its cage in ca 12 cm of water. It was not possible to determine cause of death, but either freezing or drowning was possible. The fourth hatchling was found alive and clinging to woody debris in ca 12 cm of water within its cage on 9 April 2007. In late October, this hatchling had been burrowed down 8–9 cm into rich, very damp, but not saturated, organic soil, containing either shrew or vole tunnels and earthworms ca 5 m south of a pond's edge within a woodlot. The soil in this location was moist in the fall, but flooded in April from melting snow.

Discussion.—Standing et al. (1997) reported newly emerged hatchlings entering water but soon reemerging and heading towards upland habitat. Several of our tracked hatchlings went into a wetland, but later moved out onto land. Once the hatchlings in this study found suitable overwintering locations, almost all movement stopped despite warm, sunny days. The average number of days the turtles moved was 11.9 days (range 5–28 days) over the two tracking seasons. Hatchlings moved from 253–743 m, but this measurement reflected zigzag movement and not straight-line distance. Longest single-day movements recorded were 73.4 m by one hatchling and 104 m by a second on first day of travel. Our 2005–06 findings corroborate those of Refsnider (2005) that hatchlings appear to seek out damp terrestrial areas and eventually burrow under the soil for overwintering (Refsnider 2005). While they may enter water temporarily, probably to hydrate themselves, the hatchlings seem to move out of the water to overwinter. Captive hatchling *Emydoidea* maintained during winter were observed to sleep out of the water on flat rocks in aquaria, rather than in shallow water (ML, pers. obs.)

All but one of the seven caged hatchlings (3 from 2005 and 4 from 2006) chose to overwinter in damp soil on the edge of a wetland or in a dry stream bed that would be subject to winter freezing. All six of these locations in damp soil flooded the following spring. The seventh hatchling was on a more upland site ca. 15 m from a dry stream bed. Two of the seven hatchlings were known to have survived, including the one on the more upland site, two died in the cages, possibly from drowning or freezing, although there was a minimum of 45cm of airspace and considerable floating woody debris within the cages. The remaining three hatchlings were never located, perhaps because they escaped their cages.

There was no way to determine if the hatchlings fed during the first fall, despite warm air temperatures. Some of the turtles never entered water prior to hibernation. Burrowing into moist soil that floods in spring may benefit the hatchlings by placing them in productive feeding areas that warm up quickly, rather than forcing them to move again in spring when they may be in a weakened condition. The survival of one hatchling in an upland site during the winter 2005/06 and one in winter 2006/2007 suggests that Blanding's Turtle hatchlings have the ability to survive a first winter in a terrestrial situation, even without major snow cover and with temperatures dropping to -25°C. Hatchling Painted Turtles (*Chrysemys picta marginata*) are reported to tolerate freezing in the nest chamber during winter (Storey et al. 1988). Standing et al. (1997) speculated that because several of their tracked neonate *Emydoidea* in Nova Scotia survived overnight temperatures of -5.5°C, neonate *Emydoidea* might have the ability to super cool.

Our research results suggest that hatchling Blanding's Turtles that are artificially incubated or collected from relocated nests should not be released in water, but, rather, near the periphery of wetlands that will flood in spring within heavy vegetation with damp substrates so there is opportunity for them to burrow beneath the surface. Hatchlings that are caged at presumed overwintering sites need to be checked daily once wetlands have thawed in the spring because such areas typically flood and present a potential drowning hazard for hatchlings.

Acknowledgments.—The Park District received partial funding from the Minnesota Department of Natural Resources Nongame Wildlife Program through the State Wildlife Grants program. University of Minnesota graduate student Jeanine Refsnider worked on the study 2003–04 and shared her data, analysis, and insights from Murphy-Hanrehan Park Reserve. We thank the Park District's wildlife staff and volunteers who helped track turtles. We thank John J. Moriarty for helpful comments on an earlier draft.

Experimental and field studies have demonstrated that some squamate groups can at least partially compensate for the loss of key sensory capabilities (Aubret et al. 2005; Graves et al. 1993). Among the seven recognized families of gekkotan lizards (Gamble et al. 2008), vision is clearly a key source of environmental information. They have relatively large and well-developed eyes (Greer 1989; Roth and Kelber 2004), respond to visual cues (Marcellini 1977), and at least one study has found that blinding geckos reduces hunting success (Chou et al. 1988). However, it is also clear that olfactory and auditory cues are very important to these lizards (Chou et al. 1988; Marcellini 1977; Schwenk 1993). Herein we document an adult microphthalmic Hooded Scalyfoot, *Pygopus schraderi* (Pygopodidae) that demonstrates the extent to which senses other than sight are developed among at least some gekkotans.

The specimen, SAMA R05386 (SVL 135 mm, original tail 55 mm, regrown portion 80 mm), is an adult male as determined by the possession of elongate hind limbflaps, preanal tubercles, and preanal pores. It was collected from Domagee Mission (17°56'S, 138°49'E) in far northwest Queensland, Australia, in November 1963 by L. Fawcett. No more precise information about the time and locality of collection are given.

Relative to a normal adult *Pygopus schraderi* (Fig. 1A) both the left and right eyes and adjacent scalation on this specimen are severely deformed (Fig. 1B and C). The eye opening is reduced to two small slits on the left hand side, and a small irregular opening on the right hand side. There does appear to be a small dark body internal to both eye slits, which is probably a reduced or poorly developed eyeball.

It is difficult to assess the head morphology of this specimen further without damaging it, however there is no evidence of any mechanical damage. The deformation of the scalation is greatest around the eyes but is also evident on the temporal and parietal region and the lower labials and chin shields. The midline scalation from rostral to the two frontals is relatively normal with some mild irregularities on the right side. The extensive occurrence of asymmetric scale fusions and anomalous scale shapes indicate that the most likely cause of the condition is a developmental anomaly that occurred during embryology. It is possible that the condition was developed post-hatching, as for example via a severe ophthalmic infection that spread to adjacent soft tissues and healed with extensive deformation of the scales. If the deformation is due to pathology, it must have occurred many months or years prior to the collection of the specimen, as the area is fully healed. The visual ability of this specimen is at best likely to have been far worse than a normal *Pygopus*, and it could have been completely blind. Nonetheless, this specimen was an otherwise healthy adult at the time of its collection, having attained sexual maturity, and survived and regrown its tail after at least one autotomy event. Even if damage to the eyes was acquired post-hatching, the lizard was able to maintain itself in good body condition for a significant period of its life.

The ability to at least partially compensate for loss or severe impairment of key sensory capabilities has been demonstrated in some other squamate groups (e.g., Aubret et al. 2005; Chou et al. 1988; Graves et al. 1993), but this is the first evidence of such abilities in a pygopod. The ecology of *Pygopus* is not well documented, but there are suggestions from what is known that chemoreception (olfaction or vomerolfaction) may well be central to foraging in this genus. Patchell and Shine (1986), Pianka (1986) and Kluge (1974) have reported that species of *Pygopus* appear to be arachnid specialists, foraging especially for hole-dwelling prey. Such hidden prey would best be located using chemical as well as visual cues. The existence of fossorial foraging in other pygopods such as *Aprasia* and *Ophdiocephalus* would further support the contention that senses other than sight are very well developed within the Pygopodidae (Greer 1989).

Behaviorally, pygopods differ strikingly from their limbed gekkotan relatives in their regular use of oscillatory tongue flicking while active (pers. obs), an indication that vomerolfaction is important for investigating their surroundings. This contrasts with Schwenk's (1993) evidence that geckos (but not specifically including pygopods) may be olfactory specialists, with vomerolfaction playing a lesser role. Pygopods also possess a nasolacrimal duct between the Harderian gland and the vomeronasal organ. This duct has not been recorded in conventional gekkotans,

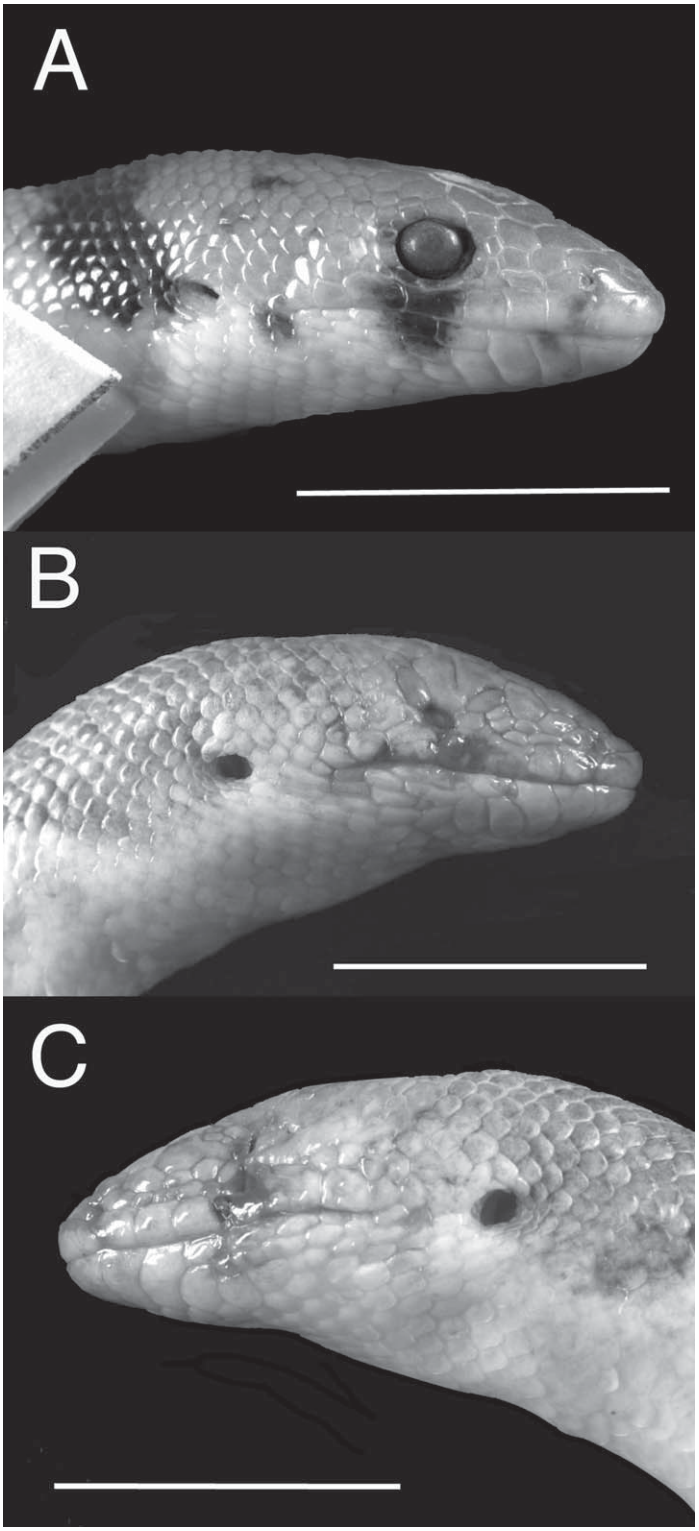

FIG. 1. Left lateral view of head of normal *Pygopus schraderi* SAMA R55293 (A); right (B) and left (C) lateral views of head of microophthalmic *Pygopus schraderi* SAMA R05386. Scale bar = 10 mm. Photographs by M. Hutchinson.

but is present in snakes, and it has been suggested that it may be a convergent adaptation associated with enhanced vomerolfaction (Rehorek et al. 2000). Relative to other gekkotans, pygopods are relatively wide-foraging and show an unusual degree of dietary specialization (Bauer 2007); as a general rule these foraging strategies are both correlated with the best developed abilities of vomerolfaction (Cooper 2007).

Multiple studies have demonstrated that pygopods are nested well inside the extant gekkotan radiation, and are relatively closely related to two other Australasian endemic gecko families; the Diplodactylidae and the Carphodactylidae (Donnellan et al. 1998; Gamble et al. 2008; Han et al. 2004). However, despite their evolutionary relationships, pygopods are strikingly divergent from all other geckos morphologically and ecologically, and remarkably convergent with the most successful limbless squamate radiation, the snakes (Bauer 2007; Greer 1989; Patchell and Shine 1986). The survival of a pygopod with greatly compromised visual ability emphasizes how the divergent evolutionary trajectory of this clade of lizards might have influenced all aspects of their biology.

Gape Width: An Alternative to Snout–Vent Length for Characterizing Anuran Size

KEVIN B. ROGERS
Aquatic Research Group, Colorado Division of Wildlife
P.O. Box 775777, Steamboat Springs, Colorado 80477, USA
e-mail: kevin.rogers@state.co.us

Snout–vent length (SVL) is the most frequently used metric to describe the size of anurans captured in the field (Hammerson 1999; Stebbins 2003). In addition to taxonomy and systematics, SVL has been commonly used in a wide variety of studies including those on age (e.g., Kellner and Green 1995; Schroeder and Baskett 1968), growth (e.g., Quinn and Mengden 1984; Ritke et al. 1991), demography (e.g., Miller 1977; Van Gelder and Rijsdijk 1987), fecundity (e.g., Quinn and Mengden 1984; Reading 1986; Tejedo 1992), mate selection (e.g., Arak 1988; Marco et al. 1998; Olson et al. 1986; Reading 1991), and locomotion (e.g., Daugherty and Sheldon 1982; Navas et al. 1999). Despite the pervasive use of SVL, little has been published on the precision and accuracy of this metric (Blouin-Demers 2003). Users may have recognized the limitations of SVL, but continued to acquire this metric presumably because of its ease of use and lack of a robust alternative. Measuring mass has become increasingly popular as a metric to describe size (Alvarez and Nicieza 2002; Carey 1978), but its properties have also not been well studied and can be more difficult to obtain in the field. Inadequacies in SVL are a direct result of the inherent malleability in the anurans being studied, as amphibian vertebral columns are somewhat flexible (Fellers et al. 1994). Unlike fish where measurements between researchers on the same individual yield functionally equivalent results (Anderson and Neumann 1996), measurements on frogs appear to be highly variable (K. Rogers, personal observation). Perhaps measurement of more rigid structures that are still clearly defined and easy to isolate would provide more consistent results. This study seeks to quantify variation in SVL measurement as well as that in some alternative metrics expected to be more reproducible between researchers.

Methods.—This study examined 100 animals representing three different year classes from nine lots of the Boreal Toad (*Anaxyrus boreas boreas*) brood stock housed at the Colorado Division of Wildlife's Native Aquatic Species Restoration Facility (NASRF) in Alamosa, Colorado. Husbandry practices at NASRF sought to emulate conditions found in the wild where possible and generally followed Scherf-Norris et al. (2002). Brood stock was reared in captivity from eggs collected in the wild. Animals were maintained on a normal circadian pattern with photoperiod matching ambient conditions. Tanks were maintained at a minimum temperature of 20°C, ranging up to 26°C on hot summer afternoons, with a UVA basking light available in each tank. Boreal Toads were fed 3-week old crickets powdered with nutrient supplements (Scherf-Norris et al. 2002) and hibernated from October 1 through May 1 at 5°C in four environmental chambers subdivided into hibernacula that could house up to five individuals each (Scherf-Norris et al. 2002).

Metrics used in this study were obtained by passing animals down an assembly line of six biologists who each measured the SVL, length of the tibiofibula (TF), width of the gape (GW; Fig. 1), and mass for every toad. Lengths were measured in mm with digital calipers, while mass (g) was obtained with digital balances tared before each measurement. An ANOVA was used to evaluate differences between readers. The coefficient of variation (CV) between readers for each Boreal Toad was also calculated, and a mean CV for all 100 toads for each body metric was determined. Differences between mean CVs were also evaluated with an ANOVA followed by Bonferroni's multiple comparison test with simultaneous 95% confidence intervals.

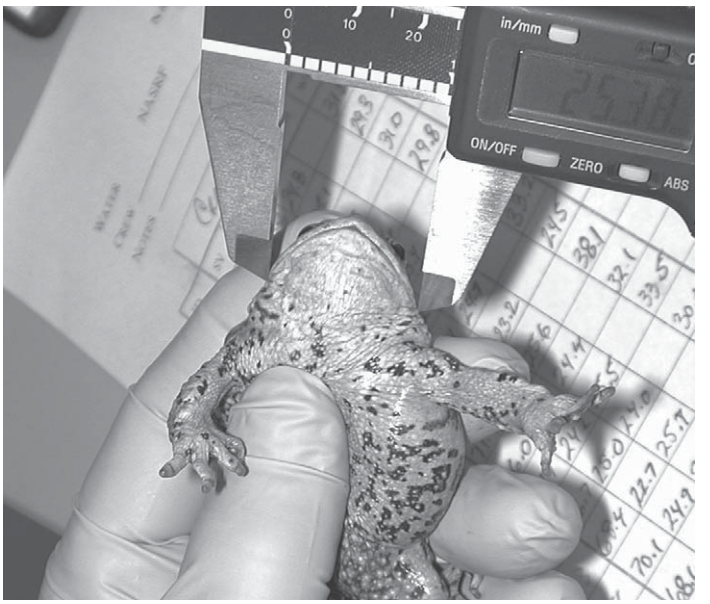

FIG. 1. Gape width measurements were taken with a digital caliper from the corners of each Boreal Toad's mouth.

Results.—There was considerable variation between readers ($P = 0.029$) in the average SVL calculated for all 100 toads measured (Fig. 2). In fact, measurements varied by as much as 30% of the calculated mean SVL for a given toad, with a mean of 12% (95% CI from 11–13%). Significant variation occurred between readers measuring TF as well ($P = 0.035$). Differences between biologists were not evident for GW ($P = 0.081$) or mass ($P > 0.999$).

Coefficients of variation were greatest for SVL and TF and least for mass (Fig. 3). Gape width did provide significantly more precision than SVL and TF, but not mass. As captive Boreal Toads used in this study were of known age, correlation of the various metrics with age was possible. Animal age ranged from 16–40 months. All metrics were positively correlated with age, with highly significant regressions ($P < 0.001$). However, mass was least predictive with an $r^2 = 0.76$. SVL and TF were intermediate, while GW showed the highest correlation with age ($r^2 = 0.85$; Fig. 4)

Discussion.—Variation in mean SVL measurements was considerable, and potentially a function of how aggressively Boreal Toads were handled during the measurement process. Body parts easily isolated for measurement produced consistent results, while those that required holding the animal in uncomfortable positions induced movement, and therefore more measurement error. It was expected that measurements of body parts less flexible than the anuran vertebral column would be more reproducible between readers. It was surprising therefore that the TF measurement was

no better than SVL for repeatability as the tibiofibula bone is rigid and should have yielded more consistent results. Perhaps subject movement induced by the awkward holding position required to measure TF played a role in the relatively large mean coefficient of variation seen for this metric (Fig. 3). GW was significantly less variable between readers. In fact this assessment is probably conservative, as much of the variation observed was due to contributions from only one of six biologists (Fig. 2). Consistency in GW measurement was facilitated by mouth corners being well defined and easily located by most readers. In addition, Boreal Toads could be held in a comfortable position while acquiring this dimension; reducing writhing that can complicate measurement of SVL and TF. This benefit was also conferred to measurement of mass. It was also not surprising that mass was the most repeatable measure used in this study, as it is the least subject to interpretation as implemented here with top-loading digital scales. Mechanical tube scales commonly used in field surveys might introduce additional measurement variation, but mass will remain a valuable metric for describing Boreal Toad size.

Perhaps the most useful aspect of measuring the width of the gape is that in addition to being very repeatable between measurers, it gave the tightest correlation with age over the size ranges examined here—a function that mass was not able to consistently achieve. While condition or plumpness of an individual can greatly affect the mass of a Boreal Toad, it often

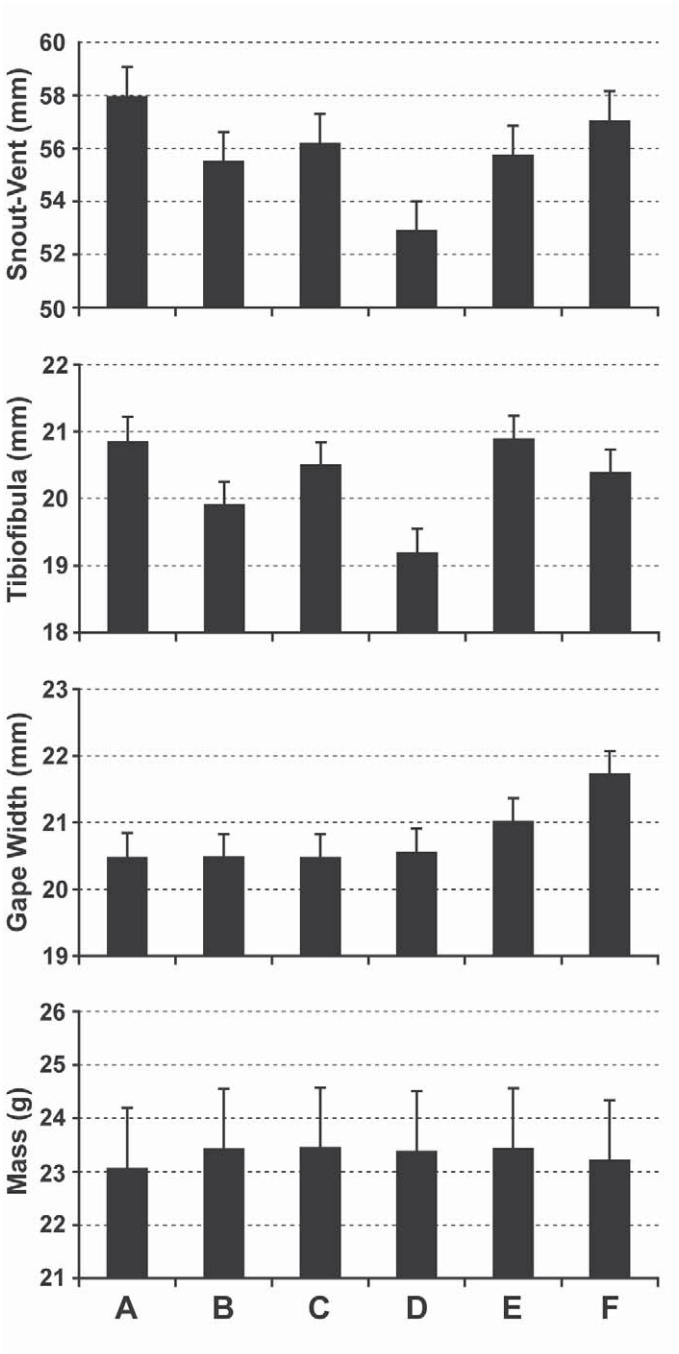

FIG. 2. Average snout–vent length (mm), average tibiofibula length (mm), average gape width (mm), and average body mass (g) for 100 Boreal Toads measured by each of six biologists (A–F) with associated standard errors.

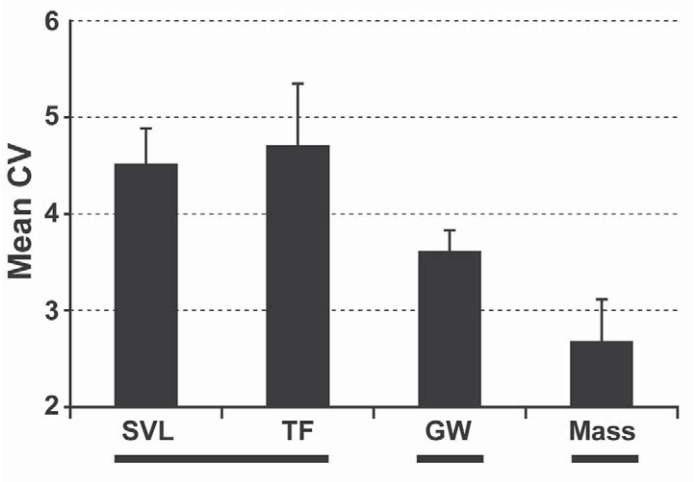

FIG. 3. Mean coefficient of variation (CV) calculated from 100 CVs generated across six biologists for snout–vent length (SVL), tibiofibula length (TF), gape width (GW), and mass with associated 95% confidence intervals. Bars sharing the same bold line below the x-axis are not significantly different ($\alpha = 0.05$).

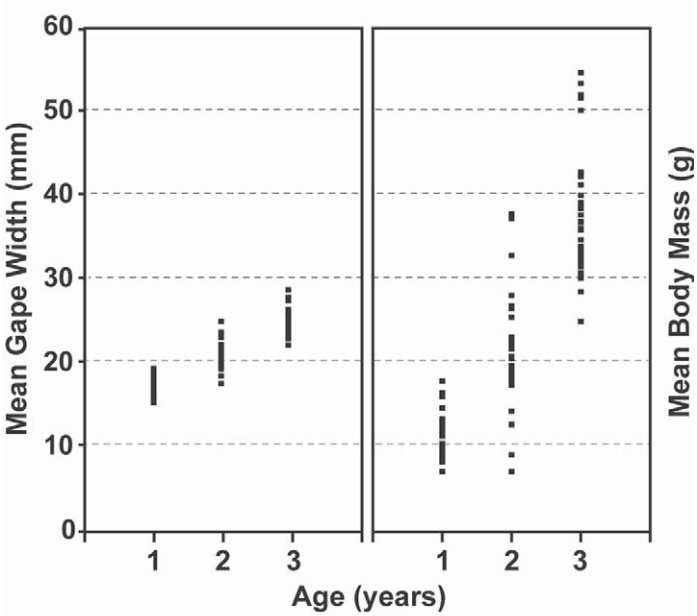

FIG. 4. Mean values for gape width (mm) and mass (g) calculated across biologists as a function of toad age.

has little to do with age. GW on the other hand is intimately tied to the animal's more rigid cranial dimensions. Though others have documented a poor relationship of SVL or mass to age in sexually mature amphibians (Halliday and Verrell 1988; Reading 1991; Wake and Castanet 1995), cranial dimensions in the first several years of a Boreal Toads life appear to more closely reflect age of the individual than mass, at least in the captive Boreal Toads used in this study. Although environmental conditions at NASRF were matched to ambient conditions, the steady diet furnished to these captive Boreal Toads might have provided for more consistent growth than would be realized in the wild. An additional study on known age wild Boreal Toads would be required to confirm the tight link between gape width and age in natural populations.

Indeed, for many analyses where only a rough index of size is required, SVL is probably adequate even with variation between readers. Certainly some of this variation can be mitigated if the same biologist acquires all of the readings. However, if precision is critical to the outcome of the study, or if a metric that is more closely correlated with age is required, then using GW is recommended.

Acknowledgments.—My gratitude is extended to J. Logan (B), T. Banulis (C), J. Eichler (D), T. Jungwirth (E), and C. Fetkavich (F) who indulged my desire to explore an alternative, and took a day to measure toad parts along with D. Schnoor for shuttling toads to the assembly line. The staff at NASRF is thanked for maintaining the population of adult toads that make this sort of study possible. M. Mahoney provided a thorough review that greatly improved the manuscript. All applicable institutional animal care guidelines were followed during the implementation of this project.

Amphibian and reptile communities are difficult to sample as many species are cryptic organisms with variable life histories and habitat requirements. One method for sampling herpetofauna is by searching under or within natural cover objects; however, this method is time intensive, non-standardized and can result in the destruction of microhabitat sites (Davis 1997). Consequently, many alternative census techniques are used (e.g., Bishop et al. 1997; Gibbons and Semlitsch 1982; Grant et al. 1992; Shirose et al. 1997; Todd et al. 2007). Ryan et al. (2002) used various sampling techniques (i.e., drift fence, coverboard arrays [i.e., ACOs] and time-constrained searches) and concluded that coverboards effectively measured herpetofauna presence-absence and revealed species not detected by drift fences and time-constrained surveys. Many researchers in North America have used ACOs to sample salamanders (e.g., DeGraaf and Yamasaki 1992; Moore 2005), snakes (e.g., Engelstoft and Ovaska 2000; Kjoss and Litvaitis 2001) and lizards (Ryan et al. 2002). Though various ACOs are commonly used, more research is needed that compares different materials for sampling herpetofauna (Grant et al. 1992; Moore 2005).

In this study, we used two ACO materials (wood and carpet) to sample herptetofaunal communities in oak-hickory forests of the upper Ozark Plateau, Missouri. This area supports more than 30 species of amphibians and reptiles, many of which are common through much of the eastern United States; therefore, the results of this study have specific applications to Midwest herpetofauna as well as other areas throughout eastern North America.

Methods.—Research was performed at three sites within the 1424 ha Daniel Boone Conservation Area, Warren County, Missouri (38.77°N, 91.38°W). The study site is dominated by a mature, secondary growth oak-hickory forest (*Quercus* spp. and *Carya* spp.) and has a rolling hill geomorphology categorized by ridge top to rock ravine with local relief (i.e., elevation change within 2.59 km^2) ranging from 46–76 m (Rittenhouse and Semlitsch 2007). A pond (160–330 m^2) centers each study site.

Artificial cover objects (ACOs) were placed at sites in April–May 2006. All transects were perpendicular to the pond edge. There were eight transects per site, primarily in second growth oak-hickory forests but extending into some sites that had been recently logged or logged and burned. Each transect was 110 m long with paired ACOs every 10 m (11 paired ACOs per transect; total of 264 paired ACOs). We used two types of ACOs, a solid untreated wood board measuring ~ 90 × 30 × 2.5 cm, and an undyed Berber style carpet slab of equal length and width, but ~1.5 cm depth. These ACOs were placed side by side, less than 10 cm apart, parallel to the transect at each 10 m interval. The soil beneath each ACO was cleared of any litter, debris, and/or large rocks to ensure that each ACO lay flat. Carpet ACOs were placed carpet side down.

ACOs were monitored from 6 June to 25 August 2006, and again from 11 April to 13 September 2007. We randomized the order in which each site was checked on collection dates. ACOs were checked during daylight hours, between 0900 and 1800 h and approximately every 10 days during the monitoring period. In order to minimize disturbance of microhabitats, ACOs were never checked more than once every seven days (Marsh and Goicochea 2003). All vertebrates beneath ACOs were recorded. Additionally, we measured salamander mass using a 20 g Pesola® (accuracy ± 0.1 g) spring scale and snout–vent length (SVL) with a hand ruler.

We recorded microhabitat variables during the weeks of 23 August 2006, 17 May 2007, and 24 July 2007. We used an infrared laser thermometer (Raytek, MT4) to measure surface temperature and a 4-prong moisture meter (Aquaterr, M-300) to measure moisture content under each ACO. We measured litter depth by inserting a metric ruler into the litter at three randomly chosen spots, 1 m from ACOs. Canopy cover was determined using a concave spherical densiometer held 1 m directly over the ACOs.

We used binomial exact tests to determine if captures were equal under wood and carpet ACOs for each species with greater than ten total captures. A bonferroni adjustment was used for comparisons ($\alpha < 0.007$). Tests were performed using SAS v9.1.3 (SAS Institute Inc.) with the exact binomial option in PROC FREQ. We were also interested in size differences among salamanders using the different ACOs. We used a T-test to compare SVL of *P. albagula* found under the two types of cover objects.

To test for microhabitat differences under wood and carpet ACOs, we descriptively compared mean temperature and moisture values for three sampling periods, fall, summer and winter. Due to differences in slope, aspect, and microhabitat, we considered each pair of coverboards to be independent.

Results.—Of the 31 possible amphibian and reptile species found within our study area, 58% (18/31) of potential herpetofauna species were captured using both types of ACOs. However, the sampling effectiveness between ACO types in detecting the most species present in our study area was not equivalent as 17 of 31 potential species were captured by wood ACOs whereas 11 of 31 species were captured using carpet. Though 18 species were captured in total, 11 species contained low total captures for our two year period (<10 captures). Within our study area, both ACO types detected the presence of 67% (4/6) of salamanders, 20% (2/10) of anurans, 75% (3/4) of lizards, and 82% (9/11) of snakes.

More amphibians and lizards were captured under wood ACOs than carpet, whereas few differences in snake captures existed between ACO types (Table 1). Of the 18 species captured using both ACOs, five of the 18 species had high captures for wood ACOs. No

species in this study were captured significantly more under carpet than wood ACOs (Table 1). *Plethodon albagula* and *Bufo americanus* were the most captured amphibian species, two snake (*Carphophis vermis, Lampropeltis triangulum*) and two lizard species, (*Eumeces fasciata, Scincella lateralis*) were also frequently captured, all of which were captured more under wood ACOs than carpet. *Diadophis punctatus* and *Virginia valeriae* were the two most captured snake species; however, captures were not particular to either ACO type. There was no significant difference in *P. albagula* SVL among the ACO types (t = -1.42, df= 3 P = 0.2511). Additionally, there were no apparent differences in soil temperature or moisture between ACO types and sampling periods.

TABLE 1. Total captures of all amphibians and reptiles. Binomial exact tests for species with greater than ten captures to evaluate if captures were equal under wood and carpet artificial cover objects. Significant *P*-values are in bold (Bonferroni adjustment for multiple comparisons $\alpha < 0.007$). "Unknown sp." represents species that escaped before identification.

	Cover Object Type			
Species	Carpet	Wood	Total	*P*
Plethodon albagula	47	256	303	**<0.0001**
Ambystoma annulatum	2	2	4	
Ambystoma opacum	0	1	1

Storeria occipitomaculata	2	1	3	
Thamnophis proximus	0	1	1	
Virginia valeriae	10	8	18	0.8145

Discussion.—Wood and carpet ACOs confirmed the presence of all known fossorial snake species in our study area. Similarly, Willson and Dorcas (2004) used plywood ACOs to sample fossorial snakes in North Carolina and detected all five species present within their study area. In particular, we captured *C. vermis* more often under wood ACOs than carpet, and both ACO types had high captures of *V. valeriae* and *D. punctatus* compared to other snake species in our study area. Wood also detected the presence of other cryptic species such as *L. triangulum.* Size of ACO may have affected our low detection of larger snake species such as *Thamnophis* spp. and *Coluber* spp., as the majority of snakes captured by ACOs were small bodied species.

In our study, we had higher lizard captures under wood over carpet ACOs and caught three of four possible species. *Sceloporus undulatus* is present in our study site but was not captured by either wood or carpet ACOs. Our study, as well as studies from different geographical regions (i.e., Grant et al. 1992; Tietje and Vreeland 1997; Hampton 2007), indicates that wood ACOs could be used across North America to sample skink species (*Eumeces* and *Scincella* spp.); however, our methods did not capture *S. undulatus* in our Midwestern study site, whereas both *S. occidentalis* and *S. undulatus* were sampled using ACOs in the East and West (Grant et al. 1992; Tietje and Vreeland 1997). Further research is needed to definitively decipher the regional effectiveness of sampling methodologies for herpetofauna guilds.

Similar to other studies of plethodontid salamanders (see review by Moore 2005 and Grant et al. 1992), Western Slimy Salamander (*P. albagula*) accounted for 94% (303/322) of all amphibians captured in our study. *B. americanus* was the only other amphibian species that was sampled in high numbers via wood ACO. Six salamander species were captured using drift fences in our study area (Hocking et al. 2008) and we caught four of the six using ACOs. However, drift fences often resulted in *P. albagula* mortality in our study area (RDS, unpublished data). Both ACOs detected the presence of six of 16 amphibian species present in our study area; however, captures for all but *P. albagula* and *B. americanus* were low in numbers. We, therefore, suggest using wood ACOs to sample for *Plethodon* salamanders because of high *P. albagula* captures compared to carpet ACOs and wood ACOs caused no mortality compared to drift fences.

In our study, as well as Houze and Chandler (2002), body size did not affect choice of ACO type by slimy salamanders (*P. albagula* and *P. ocmulgee*, respectively). In contrast, salamander (*Plethodon cinereus*) size class influenced the use of artificial and natural cover objects in Virginia (Marsh and Goicochea 2003), whereas Monti et al. (2000) found that body size class did not influence the use of artificial and natural cover objects by *P. cinereus* in Maine. A species use of ACO may vary by habitat type, regional temperatures and climate, and natural history of target organism (Davis 1997), thus sampling techniques that use ACOs may regionally differ among similar taxa. Further research is needed to definitively decipher the regional effectiveness of sampling methodologies for herpetofauna guilds, particularly those in the Midwest.

Various materials have been previously deployed as an ACO, however, no studies to date used carpet to sample herpetofauna. Overall, wood was more effective than carpet in detecting the most species in our study area. However, carpet type should be selected with caution as many carpets contain chemicals that may affect use by some taxa. One potential benefit for using carpet may be the cost of carpet over wood ACOs. We purchased wood at a cost of $7.05 per ACO whereas the cost of carpet was $2.88 per ACO. However, we were only able to conduct this comparative study for two years as carpet significantly degraded by the third sample

season whereas wood ACOs had minimal degradation. Therefore, the initial costs of carpet, though less expensive, may not be as economical in a multiyear study when compared to the initial costs and extended life span of using wood.

Acknowledgments.—We thank E. Wengert for assistance with field work. We appreciate the support and permissions provided by G. Raeker, J. Briggler, and the Missouri Department of Conservation. This project was funded by the National Science Foundation (DEB-0239943). All procedures were approved by the University of Missouri Animal Care and Use Committee (protocol # 3368).

In recent years, the use of elastomers to mark amphibians has been gaining acceptance. Several studies have reported the use of injected tags such as Visual Implant Elastomers (VIE) and Visual Implant Alpha (VIAlpha) tags (Northwest Marine Technologies, NMT) for marking individual amphibians in the field and laboratory (e.g., Gower et al. 2006; Moosman and Moosman 2006; Nauwelaerts et al. 2000). VIAlpha tags are small medical grade elastomers available in a variety of fluorescent colors. Each tag is stamped on one side with a letter (A–Z) and a number (00–99). Use of a UV light aids in detection and readability of tags. VIAlpha tags have been shown to be safe for amphibians (Buchan et al. 2005), and lack the drawbacks that may be associated with toe-clipping, such as reduced survivorship, behavioral changes, or inflammation (Golay and Durrer 1994; Lemckert 1996; McCarthy and Parris 2004). In addition, VIAlpha tags are relatively inexpensive.

VIAlpha tags are not without disadvantages. One disadvantage is the difficulty of marking frogs with loose skin. Developed for tagging fish, the injector available from NMT is not well-suited to species with skin that easily slides on the body (pers. obs.). Moreover, in amphibians, tags may migrate once injected. The webbing between toes is a stable place for elastomer tags in some amphibians (Nauwelaerts et al. 2000), but the small size of many species make this a difficult undertaking. Indeed, many studies using VIAlpha tags have involved ranid frogs, and few have focused on the viability of using tags in smaller frogs (but see Buchan et

al. 2005). Tag retention also may vary among species. Finally, VIAlpha may not be suitable for use in heavily pigmented species because the skin may obscure the tag.

We tested the use of VIAlpha tags in the neotropical treefrog *Dendropsophus microcephalus* (Hylidae). Our objectives were to: 1) test a new technique for injecting VIAlpha tags in *Dendropsophus microcephalus*, a small species with loose skin, wherein we grasp the skin with forceps, make a small incision in the skin, and then inject the tag; 2) determine whether dorsal application of tags is suitable in this species; and 3) assess whether marked frogs can be individually identified without recapture.

We marked and observed 87 male *Dendropsophus microcephalus* in the field between June and August 2008 at nocturnal breeding aggregations in the Chiquibul Forest Reserve, Belize. Frogs were hand-captured and subset was measured using photographs and ImageJ (National Institutes of Health, Bethesda, MD). Frogs averaged 24.7 mm snout-vent length (SVL) with anterior phalange length averaging less than 3 mm, precluding the use of toe clipping. All individuals were marked using red VIAlpha tags with black lettering (size = 1.0 × 2.5 mm).

Frogs were prepared for marking by grasping the loose skin of the dorsum caudal to the sacrum, close to the articulation of the femur and pelvis, with forceps and cutting a 2–3 mm slit using a pair of surgical scissors. The use of forceps provided an advantage over other techniques by preventing displacement of the incision. The tag could then easily be placed into the slit using the injector provided by NMT, with the procedure generally taking less than one minute. No anesthesia or veterinary glue was used and frogs did not demonstrate excessive signs of discomfort typical of restraint. Frogs were placed in air-filled plastic bags and monitored for several minutes, often until they began calling again, before release at the site of capture.

From the day we marked the first individual, the study ran for 50 d, with ponds checked nightly. Frogs were marked throughout the course of the study. Of 87 individuals marked, we recaptured 71 (81%) individuals. In addition, 60/89 (67%) frogs were recaptured more than once suggesting that stress of handling did not discourage individuals from returning to breeding aggregations. One individual sustained minor injury during the marking process but was observed calling the following night. No evidence of infection was observed in the marked individuals.

Our second goal was to observe the stability of tags placed at the caudal end of the dorsum, where the femur articulates with the pelvis. Few tags remained in place, generally migrating ventrally on the body. In one case, a tag was found under the chin of an individual. Tags also inverted within the frog easily, so that the printed side was no longer facing out. We were able to restore tags to the correct orientation by prodding with fingers, but the need to do so was common enough (sometimes more than one recapture per night) that the inconvenience would be substantial over time or with larger numbers of frogs. In addition, some tags were expelled from the incision site during handling, and some individuals lacked tags, but were recognized by unique markings or by the presence of the surgical site. Moreover, tags migrated in two recaptured individuals resulting in frogs being marked twice. In cases where VIAlpha tags are not easily detected, this could lead to extra incisions on the animals and wasted resources. The additional handling as a result of tag migration may have adverse effects on research, such as behavioral changes due to handling stress, although we did not see any evidence of such effects in this study.

Our final goal was to assess the use of VIAlpha tags as a marking technique that would not require recapture of individuals. The only candidate site for marking that is visible from a distance is the dorsum. While Moosman and Moosman (2006) had no migration in midbody dorsal markings in *Rana sylvatica*, the small size and lack of loose skin at midbody on our animals precluded midbody markings. We found that when tags did remain in place, they were difficult or impossible to read without the frog in hand. The light yellow pigmentation in the dorsum obscured the numbers sufficiently, even with the UV flashlight provided by NMT, that capture was necessary. Even if hand capture wasn't necessary, we would have had to approach the frog with a UV light for proper identification, and still would have risked disturbing it or affecting its behavior. In all cases we were able to discern alphanumeric identity with individuals in hand.

VIAlpha tags are appealing because of the relatively low cost (approximately US $1 per tag plus cost of injector and LED tag reading light, US $250 total), and because the tagging is relatively non-invasive. The problem of tag expulsion may be solved by the application of veterinary glue to the wound; however tag migration may remain a problem in some species and with some injection sites. By developing and implementing this new insertion technique, we successfully tracked the majority of 87 tagged frogs for almost two months. This suggests that while VIAlpha tags did not meet the goal of identifying individuals from a small distance, they did provide a marking technique that was easy to implement, fast, safe, and usually, but not always, easy to detect.

Acknowledgments.—Logistical support in the field was provided by Las Cuevas Research Station. Work was conducted under permit number CD/60/3/08(36) from the Belize Forest Department and was approved by the UCLA Institutional Animal Care and Use Committee. M. J. Mahoney and D. L. Moosman gave exceptionally helpful comments on the manuscript. This work was funded by the Columbus Zoo and Aquarium.

Amphibian trapping techniques are designed to exploit various behaviors; as knowledge regarding the behavior of the target taxa increases, sampling techniques must be adapted accordingly. Refinement of the technique increases effectiveness and reduces capture biases that might influence detection probability. Equal detectability is a critical assumption of many mark-recapture models, and unequal, imperfect, or inconstant detectability will affect estimates of population size, species richness, and site occupancy (Mazerolle et al. 2007). Therefore, it is critical that researchers consider potential sources of variation when planning studies in order to reduce capture biases, and select models for data analysis that incorporate estimates of detection probability (Mazerolle et al. 2007).

In recent years, researchers have begun to take advantage of the propensity of hylid treefrogs to use cavities as diurnal shelters (McComb and Noble 1981; Ritke and Babb 1991; Walters and Kneitel 2004) by deploying artificial refuges that mimic natural cavities to sample hylid populations (Meshaka 1996; Moulton et al. 1996). Polyvinyl chloride (PVC) pipe refuges are perhaps the most popular method for studies of hylid population ecology and ongoing monitoring efforts (e.g., Boughton et al. 2000; Campbell et al. 2009; Hirai 2006; Johnson et al. 2008; Moulton et al. 1996; Pittman et al. 2008; Smith et al. 2006; Zacharow et al. 2003). The PVC refuges are more effective for hylid sampling than traditional drift-fence arrays, and passively attract (rather than trap) frogs. As this effectively eliminates trap mortality, there is no need to remove or close "traps" between sampling periods, making PVC sampling less labor-intensive than many trapping methods. Sampling can be conducted throughout the day without fear of heat stress to "captured" animals. This method is also potentially less biased than call surveys as it facilitates year-round sampling of both genders (but see Pittman et al. 2008), and it allows identification of individual frogs for mark-recapture studies.

However, a wide variety of factors affect use of PVC refuges by hylids and can result in capture bias and influence detection probability. Although vegetative cover does not influence captures of some hylids (Moulton et al. 1996), hylids may prefer refuges in close proximity to breeding sites (Boughton et al. 2000; Pittman et al. 2008). Arboreal placement of refuges and tree type (hardwood vs. pine) may also influence the composition of the hylid sample (Boughton et al. 2000; Johnson et al. 2008; Myers et al. 2007; Townsend 1989). Capture rates may also be influenced by refuge design (i.e., pipe diameter or length, T-shaped or straight, end caps to hold water), age of pipes (i.e., outgassing of new pipes), or other variables that affect the microclimate within the PVC refuge (Bartareau 2004; Boughton et al. 2000; Buchanan 1988; Moulton et al. 1996; Zacharow et al. 2003). Season, temperature, humidity, and rainfall may also influence refuge use (Johnson et al. 2008; Pittman et al. 2008; Zacharow et. al. 2003). Some field data suggest that interspecific variation in refuge use may exist (Boughton et al. 2000; Zacharow et al. 2003), but this potential source of bias has not been explicitly investigated.

In order to unequivocally evaluate interspecific variation in PVC refuge use, it is necessary to determine the location of each study frog during each sampling period, even when frogs choose an alternative refuge (i.e., they choose natural cover rather than a PVC refuge). This can only be achieved by controlled behavioral trials or radio telemetry field studies. However, size of available radio transmitters precludes telemetry of smaller hylid species for any length of time, and the arboreal nature of some hylids makes it difficult to pinpoint diurnal refuges (Johnson 2005; M. E. McGarrity, unpubl. data). Therefore, we conducted refuge choice trials to evaluate interspecific variation in refuge preference among four species of hylids in a controlled setting in order to provide insights on potential variation in detection probability of these species in the field. As previously mentioned, numerous factors can influence variation in PVC pipe refuge use, including weather and microclimate of the PVC refuge. By conducting a laboratory study, we were able to control for many of these sources of variation and focus on behavioral variation among species. We then analyzed original field data from several of our field sites and published data from one field site (Zacharow et al. 2003), and compared laboratory and field data to evaluate the relevance of trends seen in the laboratory study.

Methods.—We collected frogs for laboratory trials during June–July 2007 from multiple urban and rural sites in Alachua, Hillsborough, and Polk Counties, Florida, USA, using PVC refuges and hand collection. Collection sites included natural marshes and swamps, retention ponds, parks, roadside and agricultural ditches, paved roads, and buildings. We conducted laboratory experiments at the University of Florida/IFAS Gulf Coast Research and Education Center (Wimauma, Florida, USA) in rooms equipped with individual climate and lighting control systems. We maintained frogs in individual 0.75 L clear plastic containers with 3 mm air holes for a maximum of 18 days; containers were disinfected between frogs. We fed all frogs crickets *ad libitum* during captivity. We set temperature to 24°C during the day (the maximum the system would allow); temperature fell to a minimum of 21°C during the night. We used a 14-hour light cycle (0630–2030 h) to approximate the natural photoperiod in central Florida during the study (June/July).

We evaluated refuge preferences in a controlled setting for four species of hylids commonly encountered in PVC refuges in the

southeastern USA: *Hyla cinerea* (Green Treefrog), *H. squirella* (Squirrel Treefrog), *H. femoralis* (Pine Woods Treefrog), and *Osteopilus septentrionalis* (Cuban Treefrog, nonindigenous). We conducted 30 individual trials per species to evaluate refuge preference; each frog participated in only one refuge choice trial. We placed each frog into a 38 L aquarium with a wet sand substrate and screen lid. Since we were unable to regulate humidity in the room, we used the wet sand substrate to increase relative humidity in the aquarium to approximately 65% to prevent desiccation and minimize variation. We offered the frog a choice of two refuges placed at opposite ends of the aquarium: a PVC pipe installed vertically in the sand (3.8 cm diameter, 20 cm tall) and an herbaceous plant (*Vinca* sp., ~20 cm tall). We alternated the placement order of the two refuges within the aquarium to control for potential directional bias in refuge choice. Although the plant was not a native Florida species, all hylid species in this study readily used it when it was the only refuge provided and it closely mimicked the structural complexity of small, native shrubs. We initiated trials at 2000 h and recorded refuge choice (i.e., PVC pipe, plant, other location) at 1000 h the following day, by which time frogs in natural habitats would likely have sought diurnal shelter. After completion of each trial, we marked indigenous hylids with visible implant elastomer to prevent re-capture (and re-testing), and released them at the site of capture. Since *O. septentrionalis* is an invasive, nonindigenous species in Florida, we euthanized these frogs immediately after trials by applying 20% benzocaine to the skin of the ventral surface followed by freezing for 48 hrs. Frog collection techniques, captive maintenance, experimental trials, and euthanasia procedures were approved by the Institutional Animal Care and Use Committee of the University of Florida (protocol E870).

We evaluated frequency of refuge use in the field with data we collected during several previous studies using PVC pipe refuges. We deployed ground-based PVC pipe refuges in 100 × 100 m grids of 121 pipes each in flatwoods habitat at sites in the Lower Suwannee National Wildlife Refuge (LSNWR, Chiefland, Florida, USA; August 2003–July 2004), Wekiwa Springs State Park (WSSP, Apopka, Florida, USA; July 2006–February 2007), and Flatwoods Wilderness Park (FWWP, Thonotosassa, Florida, USA; August 2006–June 2007). We monitored these PVC refuges at 3–4 week intervals, and individually marked each frog by toe clipping (LSNWR) or using a combination of visible implant elastomer with toe clipping (WSSP, FWWP; Hoffmann et al. 2008). We also evaluated frequency of refuge use from data in a published study that used transects of ground-based PVC refuges to sample hylid populations (at weekly intervals) at sites between breeding ponds and mesic hardwood hammocks (Gainesville, Florida, USA; August 2001–April 2002; Zacharow et al. 2003). We calculated capture frequency (i.e., number of individually marked frogs captured once, twice, etc., *not* frequency of presence/absence of any frog in a given pipe) and mean number of captures per frog for each species at each site. Since frogs were individually marked, we were able to determine frequency of capture for each frog.

We evaluated variation among species in frequency of refuge use during controlled behavior trials using a Pearson Chi-square test (SYSTAT 10.2, SYSTAT Software Inc., Richmond, California, USA; $\alpha = 0.05$). We evaluated variation among species in frequency of refuge use at our field sites (number of captures per individually marked frog) using ANOVA with *a priori* contrasts ($\alpha = 0.05$).

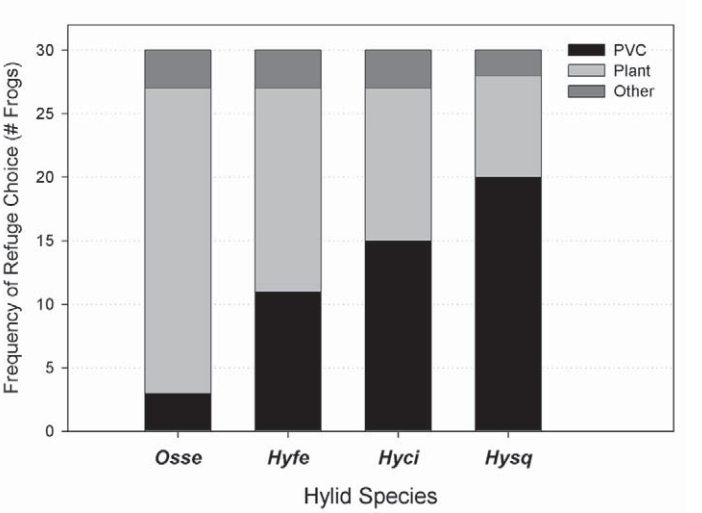

FIG. 1. Frequency of refuge choice for four hylid species (N = 30/species): *Osteopilus septentrionalis* (*Osse*; Cuban Treefrog), *Hyla femoralis* (*Hyfe*; Pine Woods Treefrog), *H. cinerea* (*Hyci*; Green Treefrog), and *H. squirella* (*Hysq*; Squirrel Treefrog). "PVC" indicates vertical PVC refuge, "Plant" indicates *Vinca* sp. plant, and "Other" indicates other (exposed) resting places in the aquarium.

Results.—Frequency of refuge use during controlled behavior trials differed significantly among species ($\chi^2_{0.05, 6} = 21.61$, $P = 0.001$; Fig. 1). *Osteopilus septentrionalis* chose to rest in the plant eight times as often as the PVC pipe, whereas *Hyla squirella* chose the PVC pipe more than twice as often as the plant. The remaining two species, *H. femoralis* and *H. cinerea*, did not exhibit an obvious refuge preference. Individuals of all species preferred to use PVC pipe and plant refuges as diurnal shelters, as opposed to more exposed areas of the aquarium (Fig. 1), and rarely chose to rest elsewhere (i.e., on sand substrate, on glass walls, or under edge of lid).

Frequency of capture in PVC refuges in the field also varied among species (Table 1). When data from our field sites (LSNWR, WSSP, FWWP) were subjected to ANOVA, mean number of captures (per individual frog) differed greatly among species ($F = 12.173$; $P < 0.001$). Mean number of captures of *H. squirella* and *H. femoralis* at our field sites were similar ($P > 0.1$), and were significantly higher than the mean number of captures per *O. septentrionalis* ($P < 0.001$). Mean number of captures of *H. squirella* differed by 33% (Table 1) between our study site and the site used by Zacharow et al. (2003); however habitat also differed greatly between these sites (respectively, flatwoods vs. breeding ponds and surrounding hardwood hammock). Across all sites (including Zacharow et al. 2003), native *H. femoralis*, *H. squirella*, and *H. cinerea* were at least 1.5 times more likely to be recaptured than *O. septentrionalis*.

Discussion.—We identified significant interspecific variation in artificial refuge use that may present a significant source of bias when using PVC refuge sampling. Our laboratory trial setup provided the advantage of controlling for climatic, microclimatic, seasonal, and other variables that might obscure interspecific variation in frog behavior in the field, and yielded insights to

TABLE 1. Frequency of capture at field sites for four hylid species: *Osteopilus septentrionalis* (Cuban Treefrog), *Hyla femoralis* (Pine Woods Treefrog), *H. cinerea* (Green Treefrog), and *H. squirella* (Squirrel Treefrog). Data are shown as the number of frogs captured *x* times at a given site, followed in parentheses by the percent of total frogs of that species captured *x* times. Sources correspond to abbreviations in study area descriptions (ZACH corresponds to Zacharow et al. 2003).

Number of captures / frog	*O. septentrionalis*		*H. femoralis*		*H. cinerea*	*H. squirella*	
1	65 (71%)	77 (71%)	205 (45%)	53 (52%)	106 (58%)	84 (60%)	70 (39%)
2	23 (25%)	22 (20%)	97 (21%)	14 (14%)	42 (23%)	17 (12%)	39 (22%)

guide future field studies. However, these laboratory trials were limited, in that they restricted the refuge choices available to the frogs, rather than mimicking the natural conditions where many natural refuge choices are available around each artificial PVC refuge. Therefore, we used data from field studies to evaluate the applicability of our laboratory results to more natural settings. Capture frequencies from PVC sampling field studies have been used to make comparisons of interspecific variation in site fidelity (Zacharow et al. 2003), and may also be good descriptors of fidelity to PVC refuges, or the propensity of a species to seek shelter in them. Theoretically, individuals of a species that prefers PVC refuges to more natural shelters will be recaptured in the PVC refuges more frequently. Factors including interspecific differences in physiology, seasonal habitat use, site fidelity, susceptibility to predation, and microhabitat preferences likely contribute to variation in PVC refuge use among species.

Capture frequencies from field studies are consistent with the results of our controlled behavioral trials. During behavioral trials, *Hyla squirella* showed an obvious preference for PVC pipes over plant refuges (Fig. 1). In the field, *H. squirella* had the highest documented number of captures per frog (Table 1; Zacharow et al. 2003), in keeping with the demonstrated tendency of this species to choose PVC refuges under controlled laboratory conditions. In addition, *H. squirella* were nearly seven times more likely to choose a PVC refuge during behavioral trials than *Osteopilus septentrionalis*, which preferred to seek refuge in the plant as opposed to the PVC pipes. Similarly, *O. septentrionalis* at our field sites were much less likely to be recaptured in PVC refuges than native hylids; only 28% of *O. septentrionalis* were captured more than once. This suggests that, although this species is well known to use PVC refuges in the field, they may use these shelters less frequently than other species, especially when alternative refuges are available. Overall, native hylids were 1.4–2.1 times more likely than *O. septentrionalis* to be recaptured in the field. Capture frequencies and mean number of captures per frog were similar for each species between field sites (Table 1), with the greatest amount of variation seen for *H. squirella* between sites in different habitat types.

Although artificial PVC refuges are the most effective method for sampling hylids currently available, sources of potential capture bias must be carefully considered in order to minimize bias, increase detectability, and reduce effects on population estimates inferred from these studies. We have identified interspecific differences in PVC refuge use as a major source of variation that could mask the difference between low abundance and low capture rate. We suggest that researchers consider behavioral differences, including diurnal refuge use, of all target species when planning PVC refuge sampling studies. When data for a given target species are not readily available in the literature, a small laboratory pilot study might be advisable to identify potential interspecific variation in refuge use and thus detectability. Furthermore, our results suggest that researchers should consider using mark-recapture methods rather than point counts to estimate population parameters, as interspecific variation in PVC refuge use may be misinterpreted as variation in relative abundance.

The implications of this interspecific variation in PVC refuge use are particularly important with regard to efforts to monitor and manage invasive species such as *O. septentrionalis*. This nonindigenous hylid is believed to impact native hylid populations through predation and competition (Knight et al. 2009; Meshaka 2001; Rice et al. 2003; Smith 2005). Management efforts to date largely consist of point-counts and removal of *O. septentrionalis* from PVC refuges used to monitor hylid populations. However, our results show that only a small portion of the population is likely to be captured using this method. The preference of *O. septentrionalis* for natural refuges, shown in this study, reduces detectability and suggests that even small numbers of *O. septentrionalis* in point-count PVC monitoring studies may be indicative of a significant infestation. Furthermore, the highly arboreal nature of this species (McGarrity and Johnson, *in press*) indicates a need for evaluation of optimal placement of PVC refuges (e.g., arboreal vs. ground-based). Until the PVC sampling method is further refined in order to maximize capture, when possible, managers should not solely rely on point-counts using ground-based PVC refuges to monitor and remove *O. septentrionalis*. Other techniques, including mark-recapture and dip netting of larvae or hand capture of breeding adults, should be considered to enhance monitoring and removal efforts that rely on PVC pipe refuges.

Acknowledgments.—We thank R. Dorazio, K. Krysko, and M. Moulton for their valuable insights, and thank J. Rechcigl, J. Price, P. Elliott, and Plant Adoption Landscapes for facilitating this study. We also thank E. Brown, T. Blunden, M. Dykes, C. Esmel, R. Haring, Y.

Kornilev, E. Roznik, C. Sunquist, and J. Watson for field assistance with frog collection, and thank T. Raffel, J. Staiger, and M. Mahoney for their comments on an earlier version of this manuscript. All research was conducted in compliance with University of Florida IACUC protocol E870.

The Western Toad, *Anaxyrus boreas*, ranges throughout the western United States, exclusive of the desert southwest (Goebel et al. 2009; Hammerson 1999). In the southern Rocky Mountains, *A. boreas* breeds in slow moving water, such as wetlands, marshes, ponds and lakes, in subalpine forest at high elevation, 2000–3500

m (Hammerson 1999). The species has been experiencing population declines in the southern Rocky Mountains since the 1970s (Carey 1993), leading to listing as a state endangered species in Colorado in 1994 (Loeffler 2001). Population declines of *A. boreas* have been linked to infection by the pathogenic chytrid fungus, *Batrachochytrium dendrobatidis* (*Bd*), which also has been implicated in causing amphibian declines throughout the world (Carey 2006; Muths et al. 2003; Scherer et al. 2005). In Colorado, there are currently 80 known breeding sites, making up 44 populations of *A. boreas*. A single population may consist of multiple breeding sites. Of the 44 populations, only one is considered viable by the Colorado Division of Wildlife (Jackson 2008). Twenty two breeding sites, from 19 populations, have tested positive for *Bd*, 35 breeding sites tested negative, and 23 breeding sites have not been tested (Jackson 2008). Two of the known *A. boreas* populations in Colorado occur within the Rio Grande National Forest of the San Juan Mountains (Jackson 2008). Our study objective was to survey areas of the Rio Grande National Forest in the San Juan Mountains for A. *boreas* populations and to determine if these populations are infected by *Bd*.

We conducted amphibian surveys from 11 to 14 August 2008 at ponds in the upper Squaw Creek drainage (~3200 m elevation), high elevation kettle ponds (~3800 m) at the base of Chief Mountain, and a pond (~3100 m) within the Little Squaw Creek (LSQ) drainage in Hinsdale County, Colorado, USA. We made a second trip to the Little Squaw Creek drainage on 4 September 2008 to resurvey the original pond (south LSQ pond) and survey an additional pond (north LSQ pond; ~3000 m). Both ponds in the Little Squaw Creek drainage are downstream (north) of the Fern Creek Trail crossing. We conducted visual encounter surveys for adult toads, juveniles, tadpoles, and egg masses in the pond and for juvenile and adult toads around the margins of the pond. Prior to approaching each pond and after each survey we sterilized all equipment, including boots, with a bleach solution, following the Colorado Division of Wildlife protocol (Livo 2004), to limit the possibility of transferring *Bd* among sites.

When toads were encountered we used sterile technique in the capture and handling of animals, following the Colorado Division of Wildlife protocol (Livo 2004), to prevent transfer of *Bd* among individuals. At the point of capture we determined sex (males possessed a nuptial pad and emitted a release call), age (metamorph, juvenile, adult), swabbed for *Bd* testing, and took digital photographs for future identification. We swabbed toads by running a sterile cotton swab over the ventral surface of the toad, including the groin, inner thighs, chin, chest, and abdomen. Swabs were stored in 70% ethanol and sent to Pisces Molecular (Boulder, Colorado, USA) for *Bd* testing using PCR analysis. All Bd analyses were conducted within three months of sample collection.

We observed no evidence of *A. boreas* at the 12 overflow ponds at the upper Squaw Creek drainage or at the kettle ponds at the base of Chief Mountain. During the first survey (14 August 2008) of the Little Squaw Creek drainage we located *A. boreas* at the pond immediately north (downstream) of the Fern Creek Trail crossing (south LSQ pond), and captured 4 (3M:1F) adults. The three male toads tested positive for *Bd*. No tadpoles or egg masses were observed, but five metamorphs were discovered during the second visit (4 September), although no metamorphs were tested for *Bd*.

During the second survey (4 September 2008) of the Little Squaw Creek drainage, we surveyed north LSQ pond, which was further north (downstream) from south LSQ pond. At this site we captured 4 adults in the pond, with a fifth toad discovered immediately west of the pond. Of the 5 toads (4M:1F), 3 of the male toads tested positive for *Bd*. No egg masses or tadpoles were observed at this site.

The Little Squaw Creek drainage site where toads were observed represents a new locality for *A. boreas* within the Rio Grande National Forest. Anecdotal reports of toads in the area had been made to the US Forest Service previously (D Gomez, pers. comm.). Based on the presence of metamorphs during the second survey of the south LSQ pond, we designate this site as the third known breeding population of *A. boreas* in the San Juan Mountains. The closest known breeding population of *A. boreas* to the LSQ drainage is ~ 11 km east in Jumper Creek and Trout Creek, Mineral County, Colorado (Jackson 2008). The observed male-biased sex ratio is typical of *A. boreas* late in the active season because males remain closer to ponds, while females typically travel further from ponds (Bull 2006; Muths 2003).

Bd analyses revealed that 6 of 9 (67%) toads (all male) exhibited a "strong positive" signal, indicating that the infection could be potentially lethal (L. Livo, pers. comm.; Carey 2006). Six of seven male toads tested positive for *Bd*, while no females tested positive. Male toads have been shown to die off from sites earlier than females (Muths et al. 2003). Differences in life history between males and females may make males more susceptible to chytrid infection because males spend longer periods of time at breeding ponds than females, allowing for greater chance of infection. Uninfected *A. boreas* at the LSQ sites, particularly males, are likely to become infected with *Bd* due to interactions with infected toads and infected habitat. Male toads may spend less time away from water sources than females, making them unlikely to leave the pond and thus avoid contracting *Bd* (Muths et al. 2003; Muths 2003).

Although the Little Squaw Creek drainage represents an additional population of *A. boreas* in Colorado, the level of *Bd* infection in the population is discouraging given that previous declines in this species have been linked to chytridiomycosis. However, the relatively high elevation of the LSQ sites correlates with a lower mean daily maximum temperature, which falls within the "reduced growth zone" of *Bd*. The lower mean daily maximum temperature may limit the success of *Bd* at the LSQ sites (Muths et al. 2008). In addition, infected toads have been shown to clear infection in the wild (Corn 2007). Further survey and *Bd* testing of the population need to occur during the breeding season to maximize captures of adults and to determine the level of reproduction that is occurring within the populations.

Acknowledgments.—This study was supported by Truman State University and the Colorado Division of Wildlife. We also thank the Colorado Division of Wildlife and the Rio Grande National Forest for their help with survey protocol and logistical support.

In recent years mass die offs and declines of amphibian populations in many parts of the world have been linked with the emerging disease chytridiomycosis, caused by the fungal pathogen *Batrachochytrium dendrobatidis* (*Bd*) (e.g., Carey et al. 2003; Daszak et al. 1999; Johnson 2006). Although *Bd* is not specifically linked with any amphibian population declines in the Midwest US, effects of this pathogen on amphibian populations in other parts of the world make it a potential threat that should not be ignored. In much of the agriculturally dominated Midwest landscape, amphibians may be especially susceptible to disease given that they are subject to a number of other stressors such as habitat loss and fragmentation, and exposure to pesticides and excessive aquatic nutrient levels. Ouellet et al. (2005) discovered *Bd* in preserved museum specimens from Minnesota, Wisconsin, Missouri, and Indiana. Green et al. (2002) diagnosed *Bd* presence in Northern Leopard Frogs (*Rana pipiens*) collected from a mortality event in North Dakota. *Bd* was detected at low prevalence levels in populations of Wood Frogs (*Lithobates sylvaticus*) in Michigan (Zellmer et al. 2008). Steiner and Lehtinen (2008) reported detection of *Bd* on samples collected from Blanchard's cricket frogs (*Acris crepitans*) in several Midwestern states, including a single detection from 17 samples collected in four southern Iowa counties. We conducted a more intensive survey for *Bd* in northern Iowa where there have been no previously reported studies.

Methods.—We sampled Northern Leopard Frogs in 22 randomly selected semi-permanent wetlands in north-central Iowa (Fig. 1) in 2006 and 2007. Wetlands were located in the Winnebago River watershed, an area within the Prairie Pothole Region that is dominated by row-crop agriculture. Sampling was conducted on both public (9 sites) and privately owned (13 sites) lands.

We captured leopard frogs for sampling by hand, with a net, or in funnel traps. All field equipment was scrubbed and soaked in bleach and/or allowed to completely dry before use in another site. In 2006 we sampled tadpoles because this stage of development is sensitive for assessing the presence of *Bd* (Berger et al. 1999). We attempted to sample 60 tadpoles per wetland in order to detect at least one affected animal, with 95% confidence, given the assumption that *Bd* prevalence in the population was 5% (DiGiacomo and Koepsell 1986). We also sampled any adult leopard frogs that were captured in the funnel traps, and we sampled metamorphs at sites where tadpole sample sizes were low, capturing them by hand or with nets. In 2007 we conducted less extensive sampling and did not focus on a particular life stage.

We used sterile fine tip swabs (Medical Wire MW113) to collect skin tissue samples. Samples were collected from tadpoles by swabbing their mouthparts (Retallick et al. 2006). The swab was rubbed over and between the teeth rows. We collected samples from adult and metamorph leopard frogs by swabbing the ventrum 30 times. The 30 strokes were allocated to 10 on each of the left and right sides of the underside of the frog and 5 on each foot. We air dried all swabs for 5 minutes, avoiding direct sunlight, and placed them in pre-sterilized microcentrifuge tubes (Fisher 05-669-17). Swabs were stored dry, as recommended by Hyatt et al. (2007). We transported the samples in a cooler and stored them in a freezer before laboratory analysis.

For samples collected in 2006 we used quantitative real-time Taqman PCR assay (Boyle et al. 2004) at the USGS National Wildlife Health Center in Madison, Wisconsin, USA, to test for the presence of *Bd* on swabs. This technique has been found to have a higher degree of sensitivity and specificity than other diagnostic assays (Boyle et al. 2004; Hyatt et al. 2007). To quantify the amount of *Bd* on the swabs we included six standards in every plate: two wells each of 10, 1, and 0.1 genome equivalents (zoospores) of *Bd*. We ran initial assays of DNA samples from two swabs pooled together. When *Bd* was detected in a well, we ran samples in triplicate for each of the individual swabs from this well. We considered samples to be positive if *Bd* was detected in all three wells. For those with equivocal results, in which *Bd* was detected in only one or two wells, we ran the sample in triplicate an additional time and considered it to be positive if *Bd* was detected in at least three

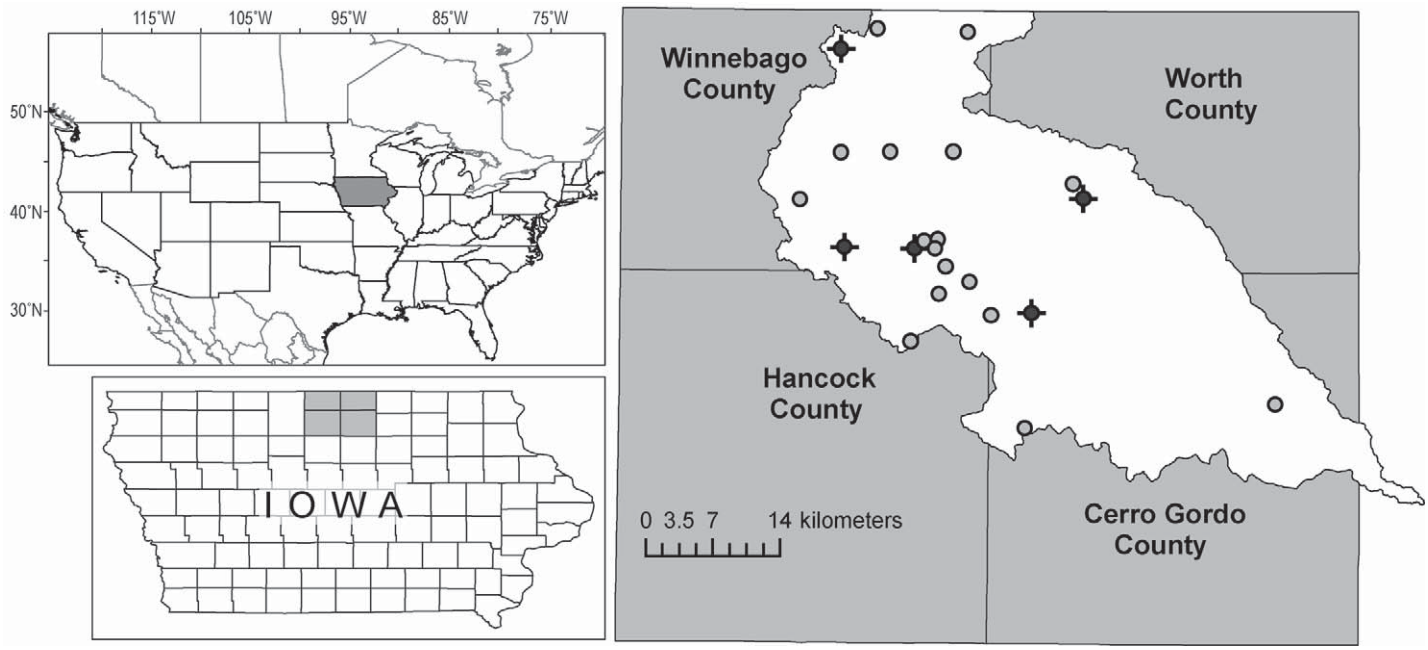

FIG. 1. Location of study sites in the Winnebago watershed of Iowa, USA, where Northern Leopard Frogs (*Rana pipiens*) were sampled for *Batrachochytrium dendrobatidis* (*Bd*). "+" indicates *Bd* detection; "•" indicates no *Bd* detection.

wells from all runs. In 2007, we pooled samples into groups of 3–8 swabs and sent them to Pisces Molecular (J. Wood, Boulder, Colorado) for PCR analysis (Annis et al. 2004).

Results.—In 2006 we collected swabs from 720 tadpoles, 25 metamorphs, and 10 adults from 22 sites. We achieved our target sample size (N = 60) in only 10 of the 22 wetlands due to inadequate trapping success. We detected *Bd* on five swabs from adults and did not detect *Bd* on tadpoles or metamorphs (Table 1). We collected each of the positive swabs from a different site, for a detection of *Bd* at 23% of all sites sampled. These five sites are located in three counties: Cerro Gordo, Winnebago, and Worth (Fig. 1). Less than 1% of all swabs were positive for *Bd*, although 62% of sites with adult samples were positive. The mean amount of *Bd* detected on the positive swabs ranged from 0.241 to 33.370 genome equivalents of *Bd*. In 2007, we collected 200 swabs from 10 sites. These samples were taken from 58 tadpoles, 141 metamorphs, and 1 adult (Table 1). None of these samples tested positive for the presence of *Bd*.

Discussion.—Although we detected *Bd* in this Iowa watershed, the overall prevalence of the pathogen was less than 1%. Because detections were not concentrated in one area, and one positive sample was collected from a fairly isolated wetland, this pathogen is likely present throughout the watershed, although at low levels. We also note that small sample sizes at many of our wetlands substantially reduced our probability of detecting *Bd* at low prevalence levels. Other field studies in the USA have reported higher prevalence rates. Pearl et al. (2007) detected *Bd* on 28% of samples, collected from all life stages of multiple species of amphibians in the Pacific Northwest. In the Northeast, Longcore et al. (2007) found 19.8% of sampled adults and metamorphs to be infected with *Bd*, including 25.7% of Northern Leopard Frogs. However, Zellmer et al. (2008) found a low prevalence of *Bd* (0.8%) in Wood Frog populations in southeastern Michigan and Woodhams et al. (2008) estimated a prevalence of 0-6.49%, with 95% confidence, of *Bd* in Northern Leopard Frogs from a site in Michigan. Although it appears likely that *Bd* is geographically distributed throughout the USA, reported prevalence varies substantially at both local and regional scales.

All of the positive samples were collected from adults, despite the small number of adult samples. This result may have been related to temperature because all of the adults were sampled earlier in the season when the temperatures were cooler. Several studies have documented higher infection levels of *Bd* at lower temperatures (Drew et al. 2006; Kriger and Hero 2006; Longcore et al. 2007; Pearl et al. 2007; Retallick et al. 2004; Woodhams and Alford 2005). It is also possible that there are differences in the prevalence of the pathogen at different life stages of a species. We note that no metamorphs or larvae were positive in either 2006 or 2007. In a field survey of the Pacific Northwest, *Bd* was found on all life stages of amphibians but at different levels of detection; adults had the highest percentage of positive samples (Pearl et al. 2007). Northern Leopard Frog tadpoles experimentally infected with *Bd* had lower activity levels than uninfected tadpoles (Parris et al. 2006). This may have caused our sample to be biased against capturing infected tadpoles since funnel traps are more likely to catch active tadpoles. Based on our results, we suggest that future studies should attempt to examine a large number of samples from multiple life stages in order to gain a more accurate assessment of the presence of *Bd* and to contribute to a better understanding of its distribution and potential population effects.

Acknowledgments.—Funding was provided by the USGS National Wildlife Health Center (NWHC), the Iowa Department of Natural Resources (DNR), and the Department of Natural Resource Ecology and Management at Iowa State University. We thank the Iowa DNR, the Cerro Gordo County Conservation Board, the Winnebago County Conservation Board, and the many private landowners for allowing us to access their properties. Susan Kwak assisted with field sampling. Vince Evelsizer and Matt Fisher, both of the Iowa DNR, helped with logistics. Rebecca Cole

NATURAL HISTORY NOTES

Instructions for contributors to Natural History Notes appear in Volume 40, Number 1 (March 2009, p. 66) and also are available online at: http://www.ssarherps.org/pages/HRinfo.php

CAUDATA — SALAMANDERS

CHIOGLOSSA LUSITANICA (Golden Striped Salamander). **LEECH PARASITISM**. Leeches are known to parasitize many freshwater species including amphibians (Romano and Di Cerbo 2007. Acta Zool. Sinica 53:750–754) and turtles (MacCoy et al. 2007. Southeast. Nat. 6[2]:191–202). Trophic relationships with amphibians are very complex, leeches predate or parasitize all life stages of amphibians, including eggs (Romano and Di Cerbo 2007, *op. cit.*), larvae (Gunzburger and Travis 2005. J. Herpetol. 39:547–571), and adults (Merilä and Sterner 2002. Ann Zool. Fennici 39:343–346). Here, leech parasitism of *Chioglossa lusitanica* in NW Spain is reported.

Chioglossa lusitanica is a streamside salamander endemic to the northwestern corner of the Iberian Peninsula (Salvador and Garcia-Paris 2001. Anfibios Españoles. Canseco Eds. 270 pp.) where it inhabits brooks, streams, and caves. Its range is well defined by precipitation, inhabiting regions with more than 1000 mm per annum, and not exceeding 1500 m elevation (Arntzen 1981. Amphibia-Reptilia 1:187–203).

Our observation was made on 20 May 2008 during herpetological monitoring of the Rio Barosa area, Barro, Spain (42.55638°N, 8.62944°W; WGS 83). This is a recreational area, due to the Barosa River cascades and adjacent channels, with some small, fast-flowing streams of high gradient. Under a stone in this area we found a large male *C. lusitanica*. During manipulation of the specimen we detected a small leech (*Batracobdella* sp.) attached to the salamander. These leeches are common ectoparasites of amphibians in Spain, having been detected on Iberian Brown Frog (*Rana iberica*) and Iberian Painted Frog (*Discoglossus galganoi*) from NW Spain (Galán and Fernandez Arias 1993. Anfibios e Réptiles de Galicia. Edicions Xerais, Lugo, España). However, to our knowledge there are no reports of leech parasitism on urodeles in NW Spain (Galán, pers. comm.), although there are reports of parasitism from other areas (see Merilä and Sterner 2002, *op. cit.*). Further studies will be necessary to assess the degree of parasitism by leeches on *C. lusitanica*.

ANURA — FROGS

ENGYSTOMOPS PUSTULOSUS (Tungara Frog) and ***HYBSIBOAS CREPITANS*** (Colombian Tree Frog). **PREDATION ON ANURAN EMBRYOS.** Fish and invertebrates are well known predators on aquatic anuran embryos (Smith et al. 2005. Copeia 2005:169–173) whereas terrestrial eggs are eaten by a variety of insects, including carabid and tenebrionid beetles (Duellman and Trueb 1994. Biology of Amphibians. Johns Hopkins University

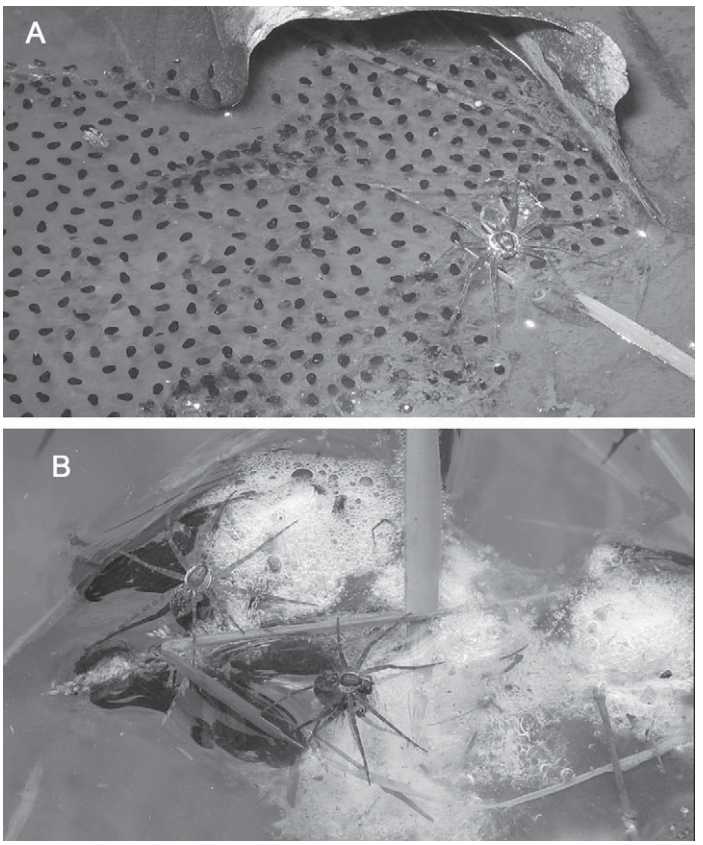

FIG. 1. Water spiders (*Trechalea* sp.) eating the embryos of *Hypsioboas crepitans* (1A) and *Engystomops pustulosus* (1B) at the same pond.

Press, Baltimore. 670 pp.). Here we report predation of Gosner Stage 10 embryos (Gosner 1960. Herpetologica 16:183–190) in the aquatic foam nest of *Engystomops pustulosus* and of aquatic embryos in Gosner Stage 17 of *Hypsiboas crepitans* by a water spider, *Trechalea* sp., family Trechaleidae (Flórez 1996. Arañas del Valle del Cauca-Colombia. p. 54 Inciva-Colciencias; Carico 2005. Trechaleidae. *In* Ubick et al. [eds.], Spiders of North America, p. 229. AAS). During fieldwork in a small temporary pond near the Coello River in Tolima, Colombia (4.25ºN, 75.3166667°W; WGS 84), on several occasions we observed water spiders (ca. 10 mm) eating the embryos of these two species (Figs. 1A, B). These observations occurred between 0915–1100 h on 15 May and during July 2007, within the rainy season and explosive reproductive period of these species.

We thank D. E. Alape for the identification of the spider. MHB acknowledges COLCIENCIAS for the PhD fellowship. Field work was supported by Fondo de Investigaciones Universidad del Tolima

LEPTODACTYLUS FUSCUS (Rufous Frog). **PREDATION**. Amphibians are common prey for a great variety of vertebrates, arthropods, and even carnivorous plants (Duellman and Trueb 1986. Biology of Amphibians. McGraw-Hill, New York; Pough et al. 1998. Herpetology. Prentice-Hall, New Jersey). *Leptodactylus fuscus* are frogs of medium size (Martins 1988. Rev. Bras. Biol. Rio de Janeiro 48[4]:969–977), found throughout much of South America in open and disturbed habitats (Heyer and Reid 2003. An. Acad. Bras. Cienc. 75[1]:39–54). Here we report the predation of an adult *L. fuscus* by an adult Common Water Snake, *Liophis miliaris*.

On 21 Oct 2007 at 2100 h, in a temporary pond in a pasture area, municipality of Tangará da Serra, state of Mato Grosso, Brazil, an adult *Liophis miliaris* was observed preying upon an adult *L. fuscus*. The snake was observed grasping the frog from the inguinal region. The snake and frog were photographed (Fig. 1). The specimens were collected and deposited at the Coleção Zoológica Unemat, in Departamento de Ciências Biológicas, Universidade do Estado de Mato Grosso, campus Tangará da Serra, municipality of Tangará da Serra, state of Mato Grosso, Brazil (MZT 15: snake, MZT 200: frog). To our knowledge this is the first report of *L. fuscus* being preyed upon by *Liophis miliaris*. We thank Paulo S. Bernarde for comments on this manuscript.

TESTUDINES — TURTLES

ACTINEMYS* (= *CLEMMYS*) *MARMORATA (Pacific Pond Turtle**). NESTING / DEPREDATION.** Although *Actinemys marmorata* is known to travel intermittently between aquatic and terrestrial habitat for upland aestivation and hibernation, dispersal, and nesting (Reese and Welsh 1997. *In* J. Van Abbema [ed.], Proceedings: Conservation, Restoration, and Management of Tortoises and Turtles—An International Conference, pp. 352–357. New York Turtle and Tortoise Society), females are thought to expose themselves to heightened risks during nesting activity. This vulnerability may play a significant role in reproductive failure and limited recruitment if either the gravid female or her eggs or offspring are depredated. Here we report the discovery of the remains of a gravid female *A. marmorata* depredated during an upland nesting foray and an observation of a Gray Fox (*Urocyon cinereoargenteus*) attempting to prey upon a gravid female in the process of nest construction.

On 31 May 2008, the depredated remains of a gravid female *A. marmorata* were found by MPB in a clearing approximately 100 m N of a vernal lake in Lake County, California. The remains consisted of a predominantly intact shell and partial skeleton found in a clearing surrounded by mixed evergreen forest and manzanita. The shell (153 mm straight-line carapace length) was situated upside down with the plastron exposed and appeared to be in an advanced stage of decomposition; post-mortem signs of desiccation and sun-bleaching were evident on both the plastron and carapace in the way of discolored epidermal scutes detached or blistering from the underlying dermal bone. Three brittle eggs remained within the abdominal cavity; one was intact, while the remaining two eggs were between 50–75% intact. Beginning in 2004 and 2005 (Bettelheim et al. 2006. Herpetol. Rev. 37:213–215) and continuing into 2008, evidence of *A. marmorata* nesting and nest depredation have been reported in an approximately .202-ha exposed clearing along the lake's western shoreline. During the summer 2008 investigation of nesting patterns at this site, nesting activity was first observed on 06 June and continued through 29 June, when nesting activity appeared to taper off and the study ended. Based on the shell's advanced stage of decomposition and the observed start of nesting activity in 2008, this female was most likely depredated during a previous year's nesting season.

Two known predators of *A. marmorata* nests, Striped Skunk (*Mephitis mephitis*) and Gray Fox (Holland 1994. The Western Pond Turtle: Habitat and History. Final report, U.S. Dept. Energy, Bonneville Power Admin. 303 pp.), were confirmed inhabiting the study area in 2008; other known predators – coyote (*Canis latrans*), raccoon (*Procyon lotor*), and opossum (*Didelphis virginiana*) (Holland, *op. cit.*) – have been seen by the authors in the vicinity (coyote) or are likely residents of the area. Any of these species may be responsible for both nest depredation and predation upon gravid females during upland nesting forays.

On 06 June 2008, AZD made the following observations during an investigation of nesting patterns from the vantage point of a camouflaged hunter's tree stand, ca. 5.2 m off the ground. At approximately 1700 h, while surveying the 0.202-ha shoreline where *A. marmorata* nesting activity appears to be concentrated, a Gray Fox was observed approaching a female turtle ca. 10 minutes into a nesting attempt. The female had trampled the surrounding dead vegetation and begun to hollow out a nest chamber when the fox began smelling the posterior end of the turtle and the nest chamber. Before this encounter could progress further, the fox became aware of the observer and left within one minute of the initial observation. The *A. marmorata* remained completely still for ca. 5 min. after the encounter before resuming nesting activity. Ultimately the female abandoned the nesting attempt and returned to the water; this abandonment was later attributed to the presence of a rock that may have obstructed the construction of the nest chamber. The following morning NRG located two freshly depredated nests surrounded by eggshell fragments within 10 m of the previous day's fox/turtle encounter.

Special thanks are in order to the California Department of Fish and Game, The Nature Conservancy, Sonoma State University, and Zoo Oakland for providing supporting staff for field monitoring and initial funding, Nicole Karres, and Vanessa Farnham for observation and identification of potential *A. marmorata* predators.

BETTELHEIM**, URS Corporation, 1333 Broadway, Suite 800, Oakland, California 94612, USA (e-mail matthew_bettelheim@urscorp.com); **NICK GEIST**, Sonoma State University, 1801 E. Cotati Avenue, Rohnert Park, California 94928, USA (e-mail geist@sonoma.edu); **ALEXANDRA ("ZANNIE") DALLARA**, Sonoma State University (e-mail dallara@sonoma.edu); and **REBECCA GORDON,** Sonoma State University (e-mail siskel14@hotmail.com),.

GLYPTEMYS INSCULPTA (Wood Turtle). **DIET.** *Glyptemys insculpta* is an omnivorous, semi-terrestrial species known to consume a variety of plant and animal material. Fungi, fruits, green leaves, flowers, and invertebrates factor prominently in reported diets (Ernst et al. 1994. Turtles of the United States and Canada, Smithsonian Press, Washington, DC). We conducted a five-year radio-telemetry study of 186 adult Wood Turtles, during which up to ~55 turtles were radio-tracked in each year. Our study area was comprised of 22 discrete stream segments along 19 streams and large rivers in the Connecticut (42.300°N, 72.600°W), Housatonic (42.233°N, 73.400°W), and Merrimack (43.800°N, 71.667°W) watersheds in Massachusetts and New Hampshire. We observed feeding behavior on 555 occasions between April 2004 and September 2008, and determined the food item on 395 occasions. On 90 occasions, we observed Wood Turtles eating the green leaves of plants, which included the following groups (number of observations; * denotes invasive species meeting the criteria of "invasive"

or "likely invasive"; Massachusetts Invasive Plant Advisory Group 2005, http://www.mass.gov/dfwele/dfw/nhesp/conservation/pdf/invasive_plant_list.pdf): Ostrich Fern (*Matteuccia struthiopteris*) (2), Bracken (*Pteridium aquilinum*) (5), unidentified sedge (*Carex* sp.) (1), unidentified grass (2), Reed Canary Grass (*Phalaris arundinacea*) (1*), Trout Lily (*Erythronium americanum*) (2), Painted Trillium (*Trillium undulatum*) (1), Bishop's Goutweed (*Aegopodium podagraria*) (1*), Jack-in-the-Pulpit (*Arisaema triphyllum*) (2), Common Milkweed (*Asclepias syriaca*) (2), Oriental Bittersweet (*Celastrus orbicularis*) (1), Spotted Joe-pye Weed (*Eupatorium maculatum*) (1), Bedstraw (*Galium* sp.) (2), hawkweed (*Hieracium* sp.) (1), Jewelweed (*Impatiens capensis*) (30), Wood Sorrel (*Oxalis montata*)(1), Japanese Knotweed (*Polygonum cuspidatum*) (1*), raspberry (*Rubus* sp.) (1), Raspberry (*Rubus idaeus*) (2), Sheep Sorrel (*Rumex acetosella*) (1), Meadowsweet (*Spiraea alba*) (1), Dandelion (*Taraxacum officinale*) (5), Red Clover (*Trifolium pratense*) (2), violet (*Viola* sp.) (3). Wood Turtles were observed eating the following fruits: Corn (*Zea mays*) (1), strawberry (*Fragaria* sp.)(13), apple (*Malus* sp.) (1), unknown raspberry (*Rubus* sp.) (5), Blackberry (*Rubus* cf. *allegheniensis*) (2), dewberry (*Rubus* cf. *hispidus*) (1), Raspberry (*Rubus idaeus*) (3), grape (*Vitis* spp.) (2).

Additional food items taken included egg masses of Spotted Salamander (*Ambystoma maculatum*) (1), trout (Salmonidae) and other fish remains (2), an unidentified bird eaten as carrion (1), fungi including, but not limited to, the genera *Russula* and *Lactarius* (27), and slugs (221) and other invertebrates (25). The tendency for slug remains to remain visible on the beak probably accounts for the high rate of observation. Substrate and surface debris taken incidentally included cobwebs (1), dirt (4), feathers (1), dead graminoids (6), dead leaves (15), mud (2), Hemlock (*Tsuga canadensis*) and White Pine (*Pinus strobus*) needles (6), and sand (1).

We obtained permission to radio-track turtles from the Massachusetts Division of Fisheries and Wildlife (permit #138.08SCRA), the New Hampshire Department of Fish and Game (by letter of authorization), and the U.S. Department of Agriculture – White Mountain National Forest (by letter of authorization). Our field methods were approved by the University of Massachusetts Institutional Animal Care and Use Committee (protocol #24-02-01; #27-02-02). We gratefully acknowledge the assistance of Renée LeBeuf in identifying the fungi species.

Submitted by **MICHAEL T. JONES**, Organismic and Evolutionary Biology, Department of Biology, University of Massachusetts, Amherst, Massachusetts 01003, USA (e-mail: mtjones@bio.umass.edu); and **PAUL R. SIEVERT**, U.S. Geological Survey, Massachusetts Cooperative Fish and Wildlife Research Unit, Department of Natural Resources Conservation, University of Massachusetts, Amherst, Massachusetts 01003, USA (e-mail: psievert@nrc.umass.edu).

GLYPTEMYS INSCULPTA (Wood Turtle). **REPRODUCTION AND DIET.** Here we report an instance of cannabilistic oophagy in a radio-equipped adult *Glyptemys insculpta* in the Connecticut River Watershed, Southampton, Massachusetts (Hampshire County) (42.233°N, 72.667°W). This event was observed during the course of a five-year radio-telemetry study of Wood Turtles in Massachusetts and New Hampshire. When our field technician located the turtle on 11 May 2005, a freshly deposited Wood Turtle egg was found on the ground immediately behind the turtle. The egg was removed from the site and incubated in the lab; it failed to initiate development. The turtle was radio-located two days later and was found eating the contents of a broken turtle egg, which we believe was also deposited by this turtle. At this time, the turtle was palpated to determine whether she was gravid, and no eggs were felt in either oviduct. On 29 May, this turtle was again palpated, and eggs were detected in both oviducts. She nested during the evening of May 31, the first of 32 radio-equipped female Wood Turtles to nest in that year (the median nesting date in 2005 was 10 June). Her nest consisted of seven eggs, one of which hatched successfully. The remaining six eggs apparently did not initiate development. Additionally, we observed egg deposition outside of the nest chamber (i.e., exposed on the ground) by another radio-equipped, free-ranging wild Wood Turtle (# 722) in West Stockbridge, Massachusetts, on 29 May 2008. While several species of terrestrial emydids have been reported to feed upon avian eggs (e.g., *G. insculpta*, *Terrapene ornata*, *Terrapene carolina*) (Legler 1960. Univ. Kansas Publ. Mus. Natur. Hist. 11:669; Ernst et al. 1994. Turtles of the United States and Canada. Smithsonian Inst. Press, Washington, DC), and cannibalistic oophagy has been reported in a captive *T. carolina* (Ernst et al. 1994, *op. cit*.), cannibalistic oophagy appears to be a rare occurrence in free-ranging turtles; we did not find reference to this behavior in other species.

We obtained permssion to radio-track turtles from the Massachusetts Division of Fisheries and Wildlife (permit 138.08SCRA), and our field methods were approved by the University of Massachusetts Institutional Animal Care and Use Committee (protocol 24-02-01, 27-02-02).

JONES**, Organismic and Evolutionary Biology, Department of Biology, University of Massachusetts, Amherst, Massachusetts 01003, USA (e-mail: mtjones@bio.umass.edu); and **PAUL R. SIEVERT**, U.S. Geological Survey, Massachusetts Cooperative Fish and Wildlife Research Unit, Department of Natural Resources Conservation, University of Massachusetts, Amherst, Massachusetts 01003, USA (e-mail: psievert@nrc.umass.edu).

GLYPTEMYS MUHLENBERGII (Bog Turtle). **MORTALITY**. On 20 June 2008, we found the intact, but desiccated carcass of a male *Glyptemys muhlenbergii* (carapace length = 92 mm; deposited in Campbell Museum, Clemson University, CUSC 2367) along the Metro-North railway line near Wingdale, Dutchess County, New York, USA. The carcass was found where the railroad traverses a freshwater marsh dominated by *Typha* sp. and *Phragmites communis*. The condition of the carcass suggested that death occurred within the previous month when the turtle became trapped between two rails of an abandoned spur line and overheated. Kornilev et al. (2006. Herpetol. Rev. 37:145–148) demonstrated that Eastern Box Turtles (*Terrapene carolina*) usually cannot climb over rails, and once trapped between railroad tracks, overheat and approach lethal body temperatures in a short time even on relatively mild days. Owing to their smaller adult body size, it is likely that railroad tracks pose an insurmountable barrier to *G. muhlenbergii*, which probably also succumb to overheating more rapidly than *T. carolina*. Although railroad-induced mortality of *T. carolina* is documented

(Palmer and Braswell 1995. Reptiles of North Carolina. University of North Carolina Press, Chapel Hill. 412 pp.; Kornilev et al., *op. cit.*), to our knowledge this is the first report of a *G. muhlenbergii* death associated with railroad tracks. Henceforth, we recommend that railroads traversing potential habitat be regarded as a potential threat to *G. muhlenbergii* populations, particularly where road crossings provide easy access to tracks (Kornilev et al., *op. cit.*). We thank Lewis Medlock for field assistance.

GOPHERUS POLYPHEMUS (Gopher Tortoise), ***CTENOSAURA SIMILIS*** (Gray's Spiny-tailed Iguana). **PREDATION**. *Gopherus polyphemus* is currently listed as a threatened and protected species in the state of Florida (Mushinsky et al. 2006. *In* Meylan [ed.], Biology and Conservation of Florida Turtles, pp. 350–375. Chelonian Research Monographs 3). Documented natural predators of *Gopherus polyphemus* include the Raccoon (*Procyon lotor*), Gray Fox (*Urocyon cinereoargenteus*), Striped Skunk (*Mephitus mephitus*), Opposum (*Didelphis virginianus*), Armadillo (*Dasypus novemcinctus*), and crows (*Corvus* sp.) (Mushinsky et al., *op. cit.*), and the introduced Savannah Monitor (*Varanus exanthematicus*) (Owens et al. 2005. Herpetol. Rev. 36:57–58). Herein, we augment this list to include the nonindigenous Gray's Spiny-tailed Iguana (*Ctenosaura similis*).

In its native range of central and southern Mexico, the Yucatán Peninsula, and Central America, *C. similis* is known to consume a variety of plants and animals, including leaves, flowers, fruits, insects, spiders, crabs, fishes, rodents, hatchling sea turtles, lizards and their eggs, birds and their eggs, bats, as well as its own eggs and hatchlings (Montanucci 1968. Herpetologica 24:305–315; Fitch and Henderson 1978. Univ. Kansas Sci. Bull. 51:483–500; Alvarez del Toro 1982. Los Reptiles de Chiapas. Instituto de Historia Natural, Tuxtla Guiterrez. 248 pp.; Van Devender 1982. *In* Burghardt and Rand [eds.], Iguanas of the World, pp. 162–183. Noyes Publications, Park Ridge, New Jersey; Krysko et al. 2003. Florida Sci. 66:74–79). In its introduced range in Florida, *C. similis* has been documented consuming at least 24 native plants and 13 invertebrates, and 14 nonindigenous plants and 2 vertebrates (Krysko et al. 2009. Florida Sci. 72:48–58).

On 28 May 2008, in a residential area on northern Gasparilla Island, Charlotte Co., Florida (26.8094°N, 82.2815°W, datum WGS84, elev. < 1 m), we observed an adult (37.5 cm SVL, 1.54 kg) male *Ctenosaura similis* enter a *Gopherus polyphemus* burrow. Later that morning, as part of an ongoing iguana removal program on Gasparilla Island, this lizard was trapped and transferred to USDA's National Wildlife Research Center Florida Field Station. Stomach contents revealed various stems, leaves, and seeds, as well as several small bones and scutes from the plastron and carapace of a juvenile *G. polyphemus* (Fig. 1).

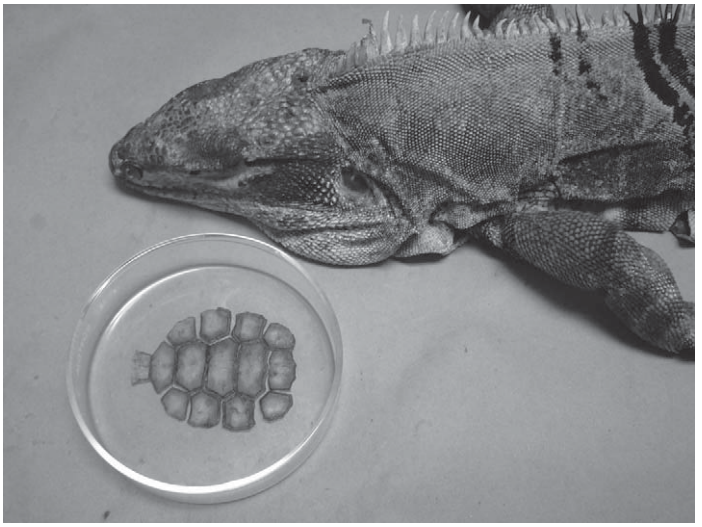

FIG. 1. Adult male *Ctenosaura similis* and scutes of the carapace of a juvenile *Gopherus polyphemus* recovered from its stomach.

Given the close proximity of *Ctenosaura similis* to *Gopherus polyphemus* burrows, ctenosaurs on Gasparilla Island undoubtedly encounter tortoises regularly. Although previous studies have noted the potential negative effects of ctenosaurs on Gopher Tortoises through burrow usurpation (Engeman et al. 2009. Herpetol. Rev. 40:84) and competition for food (Krysko et al. 2009, *op. cit.*), direct predation has not been previously documented. Invasive carnivorous reptiles represent potentially serious impacts to tortoise populations already imperiled by habitat degradation and native predators.

We thank M. L. Christie (Charlotte County Environmental & Extension Services), P. T. Hall (USDA Wildlife Services), and Gasparilla Island residents for their support.

HYDROMEDUSA MAXIMILIANI (Brazilian Snake-necked Turtle). **GROOMING BEHAVIOR.** Grooming behavior in chelid turtles of Australia and Asia is thought to facilitate removal of dead skin from the axilar and inguinal pockets and the tail and neck (Legler 1978. Can. J. Zool. 56:2449–2453; Legler and Georges 1993. *In* Glasby et al. [eds.], Fauna of Australia Series, pp. 1–27. Australian Government Publishing Service; Green 1996. Herpetofauna 26:46–47). Grooming behavior in Brazilian chelid turtles has apparently not been reported to date.

In February and October 2005 we studied four adult specimens of *H. Maximiliani* captured in Reserva Biológica Municipal Santa Cândida (21.6888889°S, 43.3444444°W, 770 m elev.), Juiz de Fora, Minas Gerais state, Brazil, under laboratory conditions. The behavioral observations were made on individual specimens

housed in an aquarium (110 × 39 × 40 cm) containing approximately 64 liters of water, using the focal animal method (Altmann 1974. Behaviour 49:227–267), during 30 min per specimen. All turtles were naturally infested by a turbellarian ectosymbiont *Temnocephala brevicornis* often associated with *H. maximiliani* (Damborenea and Cannon 2001. J. Nat. Hist. 35:1103–1118).

Grooming behavior was observed in all four specimens of *H. maximiliani*. This behavior resulted in removal of the ectosymbiont together with dead skin from the soft parts of the body, facilitated by the tomial edges of the turtle's jaws, in the axillary and inguinal pockets, sites of infestation of *T. brevicornis*.

The behavior most associated with removal of ectoparasites in freshwater turtles is aerial basking (Janzen et al. 1992. J. Herpetol. 26:217–221). Atmospheric or terrestrial basking is a common phenomenon in many species of freshwater turtles, and functions include elevation of body temperature (to enhance the capacity for activity, digestion, reproduction, vitamin D synthesis, and acceleration of egg development in adult females) and drying of the body surface to retard or remove fungi, algae, bacterial and ectoparasites (Cagle 1950. Ecol. Monogr. 20:31–54; Boyer 1965. Ecology 46:99–118; McAuliffe 1977. J. Parasitol. 63:580–581; Crawford et al. 1983. Ecology 64:989–999; Chessman 1987. Herpetologica 43:301–306; Janzen et al., *op. cit.*; Manning and Grigg 1997. Copeia 1997:579–584). However, basking has not been studied or reported in some taxa of freshwater turtles, and particularly, data on this behavior in some species of Pleurodira are scarce, being limited to observations of captive specimens (Miller 1979. Herpetologica 34:39–42). The Australian chelids *Chelodina expansa* and *C. longicollis* reportedly bask only occasionally (Webb 1978. Herpetologica 34:39–42).

H. maximiliani seldom leaves the water for basking (Souza 2004. Reptilia 40:47–51), thus grooming behavior could be an alternative strategy for removal of the ectosymbiont *T. brevicornis*. This behavior could aid a non-atmospherical basking turtle in keeping the skin in good condition and may be an adaptation to a highly aquatic mode of life (Legler, *op. cit.*). A relationship may exist between an almost completely aquatic mode of life, the absence of basking, and the occurrence of autogrooming in *C. expansa* and *Rheodytes* sp. (Legler and Georges, *op. cit.*). Grooming is common in captive *Rheodytes* sp. and *C. expansa* and serves to remove the cornified layer of the soft skin, wherever the head can reach (Legler and Georges, *op. cit.*). This report demonstrates the use of this behavior for removal of the ectosymbiont *T. brevicornis* in *H. maximiliani*.

This work was licensed by IBAMA (Process nº 02015.003546/04-11), and was performed under the principles adopted by COBEA (Colégio Brasileiro de Experimentação Animal), which were approved by the Committee of Ethics in Animal Experimentation (Pro-Rectory of Research) of the Universidade Federal de Juiz de Fora, in a meeting which took place on 04/12/2004 (Protocol nº 011/2005-CEA).

PHRYNOPS GEOFFROANUS (Geoffroy`s Side Necked Turtle). **NEST PREDATION**. There are apparently to date no published reports of predation on *Phrynops geoffroanus* nests in nature. Here we report *P. geoffroanus* nest predation by a teiid lizard, *Tupinambis teguixin*, on the Guaporé River on the border of Brazil and Bolivia. In July 2008, during seasonally falling water levels, we sought *P. geoffroanus* nests on the banks of the Guaporé River. From 600 to 1000 h daily we surveyed the river from the border region in Brazil (12.238ºS, 64.4637ºW; WGS84) to Versalles village in Bolivia (12.4396°S, 63.9271°W). The position of each nest was recorded by GPS and the total number of the eggs (predated and not predated) was also noted. Of the 39 nests found, only three were not predated by *Tupinambis teguxin*. Identification of the nest predator was confirmed by several methods: direct observation of the predation event, by the tracks made around the predated nest or characteristic marks made in the soil when the nest was excavated by the lizards, and/or the tooth marks on the egg shells remaining. *Tupinambis teguxin* was the only large carnivorous lizard seen active in the nesting area; tracks made were too large to be those of an *Ameiva*, another potential lizard nest predator indigenous to the area. This high predation rate may be related to the fact that as seasonal flood waters recede, *P. geoffroanus* is the first species to lay eggs on the emerging river banks. In this part of the Amazon, deforestation has increased recently due to land clearing for cattle ranching and illegal harvest of forest products, particularly lumber. Consequently this lizard is forced to live in the sparse riparian forest habitat, which may in turn affect the availability of its normal prey. Food may be difficult to find during high water; thus as soon as the water levels fall, *P. geoffroanus* eggs may offer the lizards an easily obtained resource.

High population densities and the efficient foraging behavior of *T. teguxin* may have significant consequences for survival of this turtle species on the Guaporé River. Further studies are needed on the effects of deforestation on this lizard's habits and turtle nest predation levels. *P. geoffroanus* is one of the few turtle species that is not widely consumed by humans in this region; consumption of its meat supposedly has caused an allergic reaction in some people, perhaps as a result of its consumption of toxic mushrooms which grow on floating logs and tree trunks in the flooded forest (Vogt 2008. Tartarugas da Amazônia. Grafica Biblos, Lima, Peru. 104 pp.). In addition, the bright orange color of this turtle's plastron suggests to some people that the meat is poisonous. Future studies should assess both the population status of this turtle species and the effects of habitat loss on the lizard species that may be its primary nest predator.

Submitted by **LARISSA SCHNEIDER (**e-mail: laribio@terra.com.br), **CAMILA R. FERRARA**, and **RICHARD C. VOGT** (e-mail: vogt@inpa.gov.br), Instituto Nacional de Pesquisas da Amazônia (INPA), Caixa Postal 478, CEP 69011-970, Manaus, Amazonas, Brazil.

TERRAPENE CAROLINA TRIUNGUIS (Three-toed Box Turtle). **ANOMALOUS SCUTATION**. Modal carapacial scutation for *Terrapene* is: 1 nuchal, 5 vertebrals, 4 pairs of costals, and 12 pairs of marginals (Dodd 2001. North American Box Turtles. University of Okalahoma Press, Norman). We have examined the carapacial scutation of 3430 *T. c. triunguis* hatchlings and found only three with a reduced number of vertebrals (each one had just four vertebral scutes). Thus a reduction in the number of vertebral scutes in *T. c. triunguis* is apparently rare.

On 18 July 2007, an adult female *T. c. triunguis* was found at Black Bayou Lake National Wildlife Refuge, Louisiana, USA. She had only one vertebral scute, the most posterior one (Fig. 1). We judged her age to be 30+ years, as her scutes were almost smooth with little trace of growth lines (Schwartz et al. 1984. The Three-toed Box Turtle in Central Missouri, Part II: A Nineteen Year Study of Home Range, Movements and Population. Dept. of Conservation, Jefferson City, Missouri). The highly atypical vertebral scutation appeared to be congenital, as opposed to injury induced, and this specimen appeared to be in good health. The fifth vertebral can be seen to be unusually narrow on the anterior end and there is midline contact between all four enlarged pairs of costal scutes; otherwise her carapacial scutation was typical in number.

We thank Gay Brantley, Bob Eisenstadt, Kelby Ouchley, Sean Miller, Robert Barham, the Black Bayou Lake National Wildlife Refuge, and the Louisiana Department of Wildlife and Fisheries for support. Work was done under Louisiana Scientific Collecting Permit No. LNHP-07-019.

CARR**, Department of Biology and Museum of Natural History, University of Louisiana at Monroe, Monroe, Louisiana 71209-0520, USA (e-mail: carr@ulm.edu).

TRACHEMYS DORBIGNI (Brazilian Slider). **MORPHOLOGY.** A kyphotic adult male *Trachemys dorbigni* (Fig. 1) was captured on 6 September 2004 in Delta do Jacuí State Park, Rio Grande do Sul, Brazil (-30.0311111°S, 51.2519444°W). The specimen had the following maximum dimensions: carapace length = 178.3 mm, carapace width = 138.7 mm, plastral length = 158.6 mm, plastral width = 104.8 mm, and the kyphotic shell height was 85.3 mm.

The highest point of the carapace was at the second vertebral shield. Besides the kyphotic deformity of the carapace, several anomalies in the epidermal shields were recorded (Bujes & Verrastro 2007. Supernumerary epidermal shields and carapace variation in Orbigny's Slider Turtles, *Trachemys dorbigni* (Testudines, Emydidae). Revista Brasileira de Zoologia 24: 666-672.). Out of 57 *T. dorbigni* (13 males, 37 females, 7 unsexed) captured at this site, only this specimen had kyphosis.

Kyphosis ("hump-back") in turtles is defined as a column deformity dorsally convex to the sagital plane of the animal. Hypothesized causes include temperature variations in the nest during embryonic development (Glazebrook and Campbell 1990. Dis. Aquatic Org. 9:83–95), premature shell fusion (Saumure 2001. Chelon. Conserv. Biol. 4:159), or yolk retraction problems (Williams 1957. Herpetologica 13:236). However, there are records of captive-held animals that have acquired the deformity as a result of metabolic bone diseases, and of wild turtles that were victims of unidentified metabolic pathologies (Gerlach 2004. Afr. J. Herpetol. 53:77–85). Thus, the reason for the occurrence of kyphosis in chelonians is unknown.

Kyphosis and related shield deformations are reported in the literature for marine turtles including *Chelonia mydas* (Rhodin

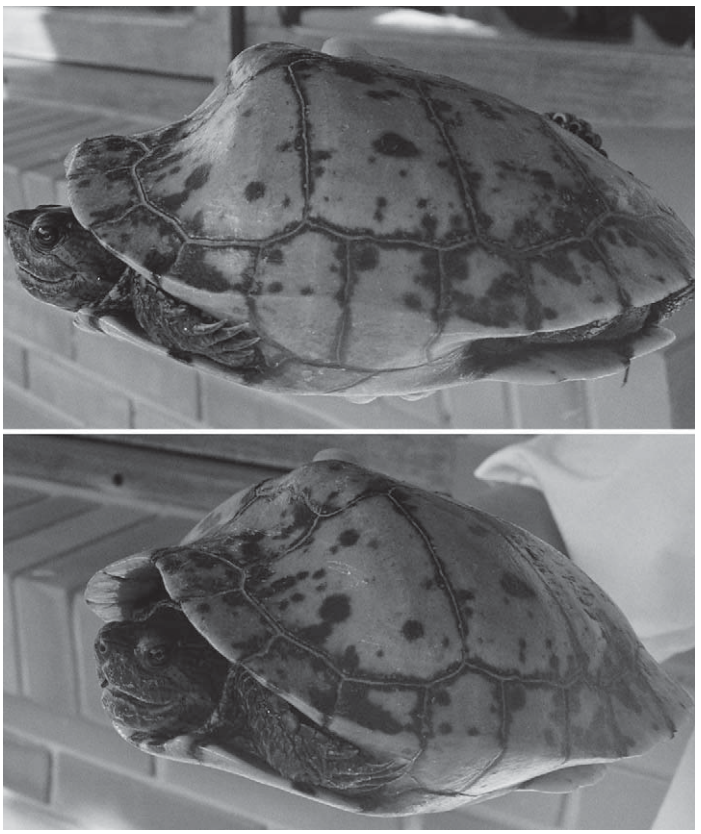

FIG. 1. Kyphotic adult male *Trachemys dorbigni* from Delta do Jacuí State Park, Rio Grande do Sul, Brazil.

et al. 1984, Brit. J. Herpetol. 6:369–373), and *Caretta caretta* (Drennen 1990. Mar. Turt. Newsl. 48:19–20), and in *Sternotherus odoratus* (Saumure 2001, *op. cit.*; Iverson 2007. Herpetol. Rev. 38:334), *Trachemys scripta elegans* (Tucker et al 2007, Herpetol. Rev. 38:337–338), *Apalone spinifera* (Burke 1994. Herpetol. Rev. 25:23), *Chrysemys (= Trachemys) scripta yaquia* (Plymale et al. 1978. Southwest. Nat. 23:457–461), and other freshwater turtle species (Stuart 1996. Bull. Chicago Herpetol. Soc. 31:60–61; Bell et al 2006. Environ. Pollution 142:457–465). This type of pathology is reported to date in five families, 12 genera, and 21 species, thus potentially occurring occasionally in all chelonian species (Plymale et al. 1978, *op. cit.*). This is the first report of kyphosis in *Trachemys dorbigni*.

SQUAMATA — LIZARDS

CNEMIDOPHORUS OCELLIFER (Whiptail Lizard)**. PREDATION.** *Cnemidophorus ocellifer* is a common lizard that is widespread in Brazil, excluding Amazonia (Vanzolini et al. 1980. Répteis da Caatinga. Academia Brasileira de Ciências, Rio de Janeiro. 161 pp.). This species utilizes open habitats in the Cerrado bioregion, frequently associated with rocks (Mesquita and Colli 2003. J. Herpetol. 37:498–509). Several aspects of this species' biology are well known, but information on predators is scarce. Mato Grosso Pantanal, Morais and Pinho (2007. Herpetol. Rev. 38:453) recorded a Road Hawk (*Ruphornis magnirostris*) preying on a juvenile *C. ocellifer*. França et al. (2008. Copeia 2008:23–38) documented the colubrid *Liophis paucidens* with two *C. ocellifer* in its stomach in Cerrado at Brasília. Here, we add to the known predator set on *C. ocellifer* with observations of predation by another colubrid snake and a centipede.

On 23 July 2008 at 1201 h, we captured an adult Pampas Snake (*Phimophis guerini*; 716 mm SVL, 297 mm tail, 15 g) of unknown sex in Fazenda Floryl (14.04670ºS, 45.89124ºW, datum: SAD69; elev. 900 m), municipality of Jaborandi, Bahia, Brazil. This individual, captured in a 60-liter bucket pitfall trap, regurgitated a juvenile *C. ocellifer* (51 mm SVL, 85 mm tail, 9 g). Ingestion had occurred headfirst. *Phimophis guerini* is a moderate-sized fossorial colubrid that occurs in different Cerrado habitats (Vaz-Silva et al. 2007. Check List 3:338–345; Sawaya et al. 2008. Biota Neotrop. 8[2]:http://www.biotaneotropica.org.br/v8n2/en/abstract?inventory+bn01308022008) and feeds on lizards (França and Araújo 2007. Braz. J. Biol. 67:33–40; Sawaya et al., *op. cit.*). França et al. (*op. cit.*) recorded a gymnophthalmid lizard eaten by a *P. guerini*, but this is the first record of predation by *P. guerini* on *C. ocellifer*.

On 29 January 2009 ca. 1100 h in the same area of the aforementioned predation event, we observed an adult centipede, *Scolopendra viridicornis* (size not measured) feeding on a juvenile male *C. ocellifer*. The abdominal region of the *C. ocellifer* was punctured and its contents had been completely consumed by the centipede. Centipedes of the genus *Scolopendra* are known to prey on anurans (Carpenter and Gillingham 1984. Caribb. J. Sci. 20:71–72), snakes (Easterla 1975. Southwest. Nat. 20:411), rodents (Clark 1979. J. Mammal. 60:654), bats (Molinari et al. 2005. Caribb. J. Sci. 41:340–346), and lizards (Butler 1970. West. Aust. Nat. II:146). This is the first record of *S. viridicornis* preying on *C. ocellifer*.

We thank Fazenda Floryl/Jatobá for assistance and IBAMA for capture permit #11596.

KENTROPYX STRIATA (NCN) and ***LEPOSOMA HEXALEPIS***. (Six-scaled Tegu). **INTERSPECIFIC INTERACTION**. The genus *Kentropyx* comprises eight heliothermic teiid species that have active feeding habits and inhabit savannas or forest environments, generally near water (Gallagher and Dixon 1992. Boll. Mus. Reg. Sci. Nat. Torino 10:125–171). Saurophagy has been recorded only for three species of *Kentropyx*; *K. calcarata* on *Iphisa elegans* (Hoogmoed 1973. Biogeographica 4:1–419), *K. pelviceps* on *Anolis trachyderma* (Duellman 1978. Misc. Publ. Mus. Nat. Hist. Univ. Kansas 65:1–352), and a specimen of *K. striata* for which remains of an unidentified lizard were found in its gut (Vitt and Carvalho 1992. Can. J. Zool. 70:1995–2006). Here, we report predation by *K. striata* on the microteiid, *Leposoma hexalepis*.

During field work at 1010 h on 13 February 2006 at a location along road from Puerto Ayacucho to Gavilán 12 km S of Puerto Ayacucho, Estado Amazonas, Venezuela, (5.57°N, 67.53°W, datum: La Canoa; elev. ~80 m), we observed an adult male *K. striata* (89.9 mm SVL) attempting to swallow an adult female *L. hexalepis* (33.9 mm SVL) on leaf litter in a small patch of secondary forest along a small creek. Air temperature was 31.4ºC; relative humidity was 65%. The lizards were collected and preserved before the *K. striata* could swallow the *L. hexalepis*; both were deposited in the Museo de Historia Natural La Salle, (*K. striata* MHNLS 17696, *L. hexalepis* MHNLS 17695). The *Leposoma* was unscarred.

Kentropix striata, which actively forages on tree branches or in leaf litter, feeds mostly on spiders, frogs, and even fruits (Gallagher and Dixon, *op. cit.*; Manzanilla and Natera 1997. Herpetol. Rev. 28:50), whereas *L. hexalepis* is non-heliothermic species that actively forages in litter (Molina et al. 2002. Herpetologica 58:485–491). Saurophagy among members of the genus *Kentropix* seems infrequent (Vitt 1991. Can. J. Zool. Vol. 69:2791–2799; Vitt and Carvalho, *op. cit.*), but *K. striata* may have the opportunity to prey with some frequency on *L. hexalepis* in this locality because of the abundance of the latter. Vitt and Carvalho (*op. cit.*) found that *Ameiva ameiva* often prey on *K. striata*; the latter in turn feed on other lizards, as in our observation, implies that trophic interactions among lizards comprise an important part of the food web in these ecosystems.

We acknowledge the funding provided by the National Science Foundation (DEB-0416160) and the Instituto Bioclon to Eric N.

Smith. Collection was made under permit 01-03-03-2050 (Gilson Rivas), and 01-03-03-1146 (Fernando J. M. Rojas-Runjaic) by the Ministerio del Ambiente (MinAmb) through Fundación La Salle de Ciencias Naturales, Caracas.

SCELOPORUS UNDULATUS (Eastern Fence Lizard). **DIET**. The Eastern Fence Lizard feeds on diverse insects, though hymenopterans (especially formicids) and coleopterans comprise the majority of their diet (Lemos-Espinal et al. 2003. J. Herpetol. 37:722–725; McCauley 1939. Am. Mid. Nat. 22:150–153). Juvenile *Sceloporus* typically eat a higher proportion of smaller prey (e.g., ants) than do adults (DeMarco et al. 1985. Copeia 1985:1077–1080). To the best of our knowledge, no author has identified invertebrate prey to species for *S. undulatus*. Hence, here we describe an observation of a juvenile *S. undulatus* consuming an unusually large lepidopteran larva that we were able to identify to species.

At 1216 h on 10 October 2007, 200 m SE of the St. Francis National Forest Head Office, Lee County, Arkansas, USA (34.75828533°N, 90.72192372°W, 110 m elev.), we collected a juvenile *S. undulatus* (39 mm snout–vent length; 10 mm head width; 2.1 g) and placed it in a clean empty cloth bag for ca. 1 h. Upon removal from the bag and subsequent processing, the lizard regurgitated an intact *Pseudaletia unipuncta* larva (Lepidoptera: Noctuidae) 38 mm in length, 7 mm in diameter, and weighing 0.7 g (Fig. 1). This prey item was only 1 mm shorter than the body length of the lizard, and represented one third of its mass.

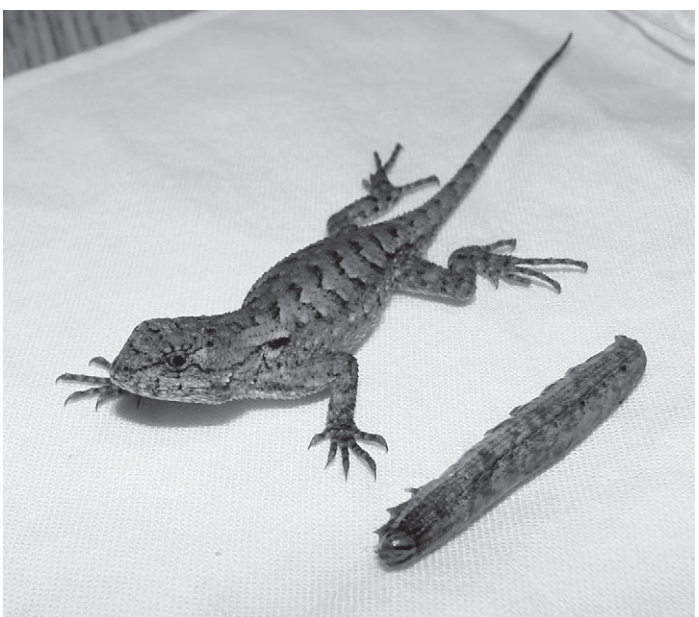

FIG. 1. Juvenile *Sceloporus undulatus* with a regurgitated Armyworm larva, *Pseudaletia unipuncta.*

This observation supports recent findings that lizards can take large prey, but gape width appears to restrict prey size (DeMarco et al. 1985. Copeia 1985:1077–1080; Shine and Thomas 2005. Oecologia 144:492–498). Consuming a prey item of this size may have increased the lizard's vulnerability to predation, but the return in energy obtained would be presumably high relative to the cost of pursuing, subduing, and swallowing (Pough and Andrews 1985. Ecology 66:1525–1533). The larval stage of *P. unipuncta* coincides with hatching of *S. undulatus* and may therefore represent an important seasonal prey source (Forbes 1954. The Lepidoptera of New York and Neighboring States. Cornell University, Ithaca, New York. 433 pp.).

We thank T. McCabe for identification of the *P. unipuncta*.

Submitted by **NICOLE A. FREIDENFELDS** (e-mail: naf11@psu.edu) and **TRACY LANGKILDE** (e-mail: tll30@psu.edu), Pennsylvania State University, 208 Mueller Laboratory, State College, Pennsylvania 16802, USA.

TUPINAMBIS MERIANAE (Common Tegu). **DIET**. Vertebrate predation on anurans is well known (Toledo et al. 2007. J. Zool. 271:170–177), and some reports cite lizards of the genus *Tupinambis* (Kiefer and Sazima 2002. Amphibia-Reptilia 23:105-108; Souza et al. 2002. Herpetol. Rev. 33:209). However, reports of *Tupinambis merianae* predation on anurans is limited to *Leptodactylus ocellatus* (Leptodactylidae) and *Rhinella schneideri* (Bufonidae) (Toledo et al., *op. cit.*; Silva and Hillesheim 2004. Herpetol. Rev. 35:399). Here, we add to available reports of *T. merianae* predation on anurans with a report of predation on the hylid frog *Scinax fuscovarius*.

At ca. 1300 h on 30 January 2008, we observed a juvenile (ca. 35 cm total length) *T. merianae* preying on an adult *S. fuscovarius* ca. 100 m NE of Sede Dam, near the small village of Rio Claro Farm, municipality of Lençóis Paulista, São Paulo State, Brazil (22.7708°S, 48.8767°W; datum: WGS84; elev. 635 m). The *S. fuscovarius* was captured by the tegu by the posterior part of the body. The tegu chewed on the frog with the latter's head and forelimbs exposed for ~1 min. The tegu pressed the treefrog to the substratum several times to assist swallowing. After completing ingestion, the tegu disappeared into nearby vegetation. The entire process lasted ~3 min.

Lizards of the genus *Tupinambis* are considered active foragers that cover large areas while foraging, mainly during the heat of the day. They are considered to have a generalist diet that includes eggs, fruits, invertebrates, and small vertebrates, among which anurans appear prominent (Pianka and Vitt 2003. Lizards: Windows to the Evolution of Diversity. University of California Press, Berkeley, California. 333 pp.). To our knowledge, this is the first report of *S. fuscovarius* as anuran prey by a lizard.

We thank Duratex, S.A. for research support.

SQUAMATA — SNAKES

APOSTOLEPIS CEARENSIS (Gomes' Burrowing snake). **DIET.** The diet of the small colubrid snake *Apostolepis cearensis* is poorly reported (Freitas 2003. Serpentes Brasileiras. Malha de Sapo Publicações e Consultorias, Lauro de Freitas, Bahia, Brazil. 160 pp.). On 24 August 2008, at 1400 h, we collected an adult *A. cearensis* (SVL = 255 mm; 4 g after prey removal) in a hen house, killed by a young chicken, near Pentecoste, Ceará, Brazil (3.82130°S, 39.33824°W, datum: WGS 84). Upon dissection, we found a *Tantilla melanocephala* that had been eaten headfirst by the *A. cearensis*. The head of the prey was partially digested (SVL ca. 215 mm; 3 g). The prey/predator mass ratio was high (0.75). The mass and length of the prey may have limited the movements of the predator, allowing the young chicken to kill it. This is the first report of *T. melanocephala* in the diet of *A. cearensis*. The snakes were deposited in the herpetological collection of Universidade Federal do Ceará (CHUFC 3019 and CHUFC 3058).

BITIS SCHNEIDERI (Namaqua Dwarf Adder). **DIET**. On 25 July 2008, a female *Bitis schneideri* (SVL = 214 mm; total length = 235 mm; 16.4 g) was found dead on the Kleinzee-Koingnaas road, Northern Cape Province, South Africa (30.1813°S, 17.2586°E, datum: WGS84). The damage to the snake exposed a recently ingested male *Bradypodion occidentale* (Namaqua Dwarf Chameleon; SVL = 80 mm; total length = 138 mm; 4.9 g). The chameleon had been ingested headfirst. Haacke (1975. Cimbebasia 4:115–128) recorded anurans (specifically of the genus *Breviceps*), geckos, skinks, and lacertid lizards in the diet of the species. This record represents the first known case of *B. schneideri* feeding on a chameleon. These two species inhabit sparsely vegetated Succulent Karoo Sandveld, and habitat structure forces chameleons to frequently cross the ground. Given that *B. schneideri* show sit-and-wait feeding habits, they are likely to be fairly opportunistic in their prey choice. Thus, though novel, this record is not surprising.

COLUBER CONSTRICTOR (North American Racer). **DEFENSIVE BEHAVIOR.** Many prey species have predator-specific responses that may go unobserved when a human is perceived as the threat. For example, horned lizards are more likely to squirt blood from their eyes when approached by a canid than when approached by a human (Middendorf and Sherbrooke 1992. Copeia 1992:519–527). On 12 October 2007, one of us (PWG) found a *Coluber c. constrictor* (total length ca. 1 m) in a wooded residential area in Aiken, South Carolina, USA. The snake was lying limp on the ground with two domestic House Cats (*Felis catus*), each ca. 50 cm away, looking at the snake, which appeared to be dead. We picked the snake up, and it hung limply for 10 seconds until we observed it flicking its tongue, indicating that it was alive. The snake was released 2 m away from the cats and immediately fled approximately three additional meters into a pile of logs. The following day, another observer (Carolyn C. Gibbons) saw a *C. constrictor* of the same size (possibly the same individual) lying in pine straw ca. 30 m from the release site of the previous day. The snake was limp and its head was beneath its body. One of the same cats was looking at it. The cat was picked up and removed, and the snake was nudged. It immediately became active and crawled rapidly into a nearby brush pile.

Typical behavior of racers when pursued by humans is to continue moving to escape, often climbing into vines, bushes, or trees and, if cornered, the species often assuming a defensive pose with mouth open and striking repeatedly (Ernst and Ernst 2003. Snakes of the United States and Canada. Smithsonian, Washington DC; Gibbons and Dorcas 2005. Snakes of the Southeast. Univ. of Georgia Press, Athens). A single observation of death feigning was reported by Lynch (1978. Blue Jay 36:92–93) for *C. c. flaviventris* in Saskatchewan.

Our interpretation of the observed phenomenon is that a snake defensive behavior was revealed that may be a prevalent response to felids that are more agile and likely to capture the snake than are humans. Such predator-specific responses might not be invoked when a human is perceived by the snake to be the primary threat. Thus, death-feigning might be much more prevalent among some snake species, even common species like *C. constrictor*, than is typically observed by humans.

We thank Michael E. Dorcas for comments on the original manuscript.

CROTALUS POLYSTICTUS (Mexican Lance-headed Rattlesnake). **MAXIMUM ELEVATION**. We observed 25 *Crotalus polystictus* (11 males:14 females) near Acambay, Estado de México, México (19.862º N, 99.802º W, NAD83) between 25 June and 21 August 2007. All snakes were encountered at elevations of 2715–2739 m. Previous to these encounters, *C. polystictus* was known to inhabit a vertical distribution of 1450–2600 m (Campbell and Lamar 2004. Venomous Reptiles of the Western Hemisphere. Cornell University Press, Ithaca, New York. 870 pp.). Habitat was similar to other areas where we have observed *C. polystictus* in the Estado de México, consisting of relatively level, seasonally mesic grassland.

ratorio de Herpetología, Apartado Postal - 513, San Nicolás de los Garza, Nuevo León, C. P. 66450, México; and **ALAN KARDON**, San Antonio Zoological Gardens, 3903 N. St. Marys Street, San Antonio, Texas 78212, USA.

CROTALUS TRISERIATUS (Mexican Dusky Rattlesnake). **CANNIBALISM**. Cannibalism is widespread among snakes, and is an important element of the ecology of many species (Polis and Myers 1985. J. Herpetol. 19:99–107). Cannibalism has been observed in several species of rattlesnakes (Mitchell 1986. Cannibalism in Reptiles: A Worldwide Review. SSAR Herpetol. Circ. 15. 37 pp.; Campbell and Lamar 2004. The Venomous Reptiles of the Western Hemisphere. Cornell University Press, Ithaca, New York. 870 pp.). In almost all cases involving wild snakes, prey items were young animals (neonates or juveniles) (Mitchell, *op. cit.*; Campbell and Lamar, *op. cit.*). To our knowledge, cannibalism has not been reported in *Crotalus triseriatus*. Here, we describe cannibalism of an adult *C. triseriatus*. On 1 August 2007 at 1228 h, one of us (EMD) encountered an adult male *C. triseriatus* (480 mm SVL, 56.5 mm tail length) basking among bunchgrass in the municipality of San José del Rincón, Estado de México, México (19.668ºN, 100.185ºW, NAD83) at a elevation of 2824 m asl. The snake contained a very large, obvious food bolus, weighed 218.4 g, and was retained in captivity until defecation.

On 1 August 2007, the snake deposited a fecal sample that contained ventral and keeled dorsal scales as well as vertebral bones from a snake, a second sample was obtained on 2 August and contained additional vertebral bones and a section of skin consistent with the dorsal pattern of *C. triseriatus*. Two additional fecal samples contained scales and vertebral bones, On 19 August the snake deposited a fifth and final fecal sample which included a rattle with 4 intact segments measuring 4.2, 4.2, 4.1, and 4.1 mm in width. The snake weighed 165.7 g after defecating, 52.7 g less than when captured. *Crotalus triseriatus* is the only rattlesnake we have observed at this site. The only other rattlesnake which might occur nearby (based on geographic proximity and habitat type) is *C. molossus*, a species with much larger rattles, even as juveniles.

Based on the size of rattle segments, the *C. triseriatus* ingested likely was ca. 400–450 mm SVL (Campbell and Lamar, *op. cit.*; pers. obs.), only slightly smaller than the snake that consumed it. Although we have no evidence from which to infer a cause of death, we mention that the snake was encountered at a site frequently traversed by local inhabitants, and from where they describe killing many *C. triseriatus*. We consider it possible that the smaller individual was killed by humans and later consumed as carrion by the larger snake.

Submitted by **ESTRELLA MOCIÑO-DELOYA** (e-mail: allertsemoci@yahoo.com), and **KIRK SETSER,** Departamento de Biología Animal, Facultad de Ciencias, Universidad de Granada, C.P. E-18071, Granada, España.

CROTALUS TRISERIATUS (Mexican Dusky Rattlesnake). **REPRODUCTION.** On 8 October 2007, one of us (KS) encountered an adult female *Crotalus triseriatus* (SVL 521 mm, tail 40 mm, mass 174 g) near San José del Rincón, Estado de México (19.668ºN, 100.207ºW; NAD83) within mixed pine-oak woodland and bunchgrass at an elevation of 3091 m. On 1 November 2007, at which time it weighed 182 g, this snake was transported to the Houston Zoo, where she was subsequently maintained. On the night of 26 December 2007, this snake gave birth to 12 live, healthy neonates as well as a single unfertilized ovum. Neonates were weighed on 28 December (3.9, 4.3, 4.4, 4.4, 4.4, 4.5, 4.6, 4.6, 4.6, 4.8, 4.8, and 4.9 g); the unfertilized ovum was not weighed. Mean neonate mass was 4.5 g, total clutch mass (exclusive of the ovum) was 54.2 g. The female weighed 155 g immediately following parturition. Relative clutch mass (calculated using the female's weight on 1 November) was 0.30. The female fed readily throughout her pregnancy, including taking a juvenile *Mus musculus* on 26 December 2007.

Few data on reproductive phenology are available for *C. triseriatus*. Campbell and Lamar (2004. The Venomous Reptiles of the Western Hemisphere. Cornell University Press, Ithica, New York 870 pp.) summarize data from three wild litters, all born in July, and an additional litter born to a captive female on 30 October. Ramírez-Bautista et al. (1995. Herpetol. Rev. 26:12–13) present data on embryos contained by three gestating females collected between July and September. Available data from three central Mexican highland congeners (*C. aquilus*, *C. polystictus*, and *C. transversus*) suggest that these species typically give birth during summer months (Campbell and Lamar, *op. cit.*; pers. obs.). The paucity of data makes it difficult to evaluate the phenology of the event we describe; however, we suggest that it is probable that exposure to a captive environment induced this female to accelerate development of her litter. It seems unlikely that wild female *C. triseriatus* give birth during winter months or produce multiple litters per year. We also note that a recent report of a *C. aquilus* litter born in March to a captive gravid female collected on Cerro del Tenayo, Estado de México might represent a similar phenomenon (Correa-Sanchez and Rivera-Velázquez 2007. Herpetol. Rev. 38:205).

DIADOPHIS PUNCTATUS (Ringneck Snake). **OPHIOPHAGY**. *Diadophis punctatus* is known to consume a variety of invertebrates and small vertebrates, including snakes. However, the diet of the Mexican Ringneck Snake, *D. punctatus dugesi* in central México is not well known. We are aware of just a single published record (Sánchez-Herrera 1980. Bull. Maryland Herpetol. Soc. 16:9–18), describing a captive *D. p. dugesi* from the Distrito Federal that ate a *Conopsis lineata*.

Garter snakes (*Thamnophis* species) have commonly been recorded in the diet of *D. punctatus* in other areas of North America. Prey species have included *T. couchii, T. hammondii, T. ordinoides*,

and *T. sirtalis* (Ernst and Ernst 2003. Snakes of the United States and Canada. Smithsonian Books, Washington D.C.; Wiseman et al. 2007. Herpetol. Rev. 38:344–345; O'Donnell et al. 2007. Toxicon 50:810–815).

Here we report two additional observations of *Thamnophis* predation by *D. punctatus*. At 1000 h on 25 June 2007, one of us (AMH) collected an adult female *D. p. dugesi* (522 mm SVL, 87 mm tail length, 52.0 g including food bolus). The snake was found basking in a dry concrete canal near San Pedro de los Metates, Municipio de Acambay, Estado de México (19.905ºN, 99.878ºW, NAD83; ca. 2500 m elev.). We palpated an obvious food bolus to the snake's mouth revealing that the snake had recently consumed a small male *T. scaliger* (estimated at ca. 250 mm total length). The prey item was repalped to the snake's stomach; the *Diadophis* was maintained in captivity for ca. 1 month. Following several defecations, the snake weighed 39.1 g when released on 23 July 2007.

At 1334 h on 31 July 2008, one of us (KS) collected an adult male *D. p. dugesi* (340 mm SVL, 82 mm tail length, 18.3 g). The snake was found loosely coiled on bare soil between clumps of bunchgrass (zacatón) near La Estancia, Municipio de Acambay, Estado de México (19.862ºN, 99.803ºW; ca. 2725 m elev.). A few hours after capture, this snake defecated remains of a snake skin identifiable as *Thamnophis*. We were unable to identify the remains to species; however, *T. eques, T. melanogaster, T. scalaris,* and *T. scaliger* have been observed at this site.

Submitted by **ANDRÉS ALBERTO MÉNDOZA-HERNÁNDEZ**, Museo de Zoología de la Facultad de Ciencias, Universidad Nacional Autónoma de México, A.P. 70-399, C.P. 04510, México D.F. PYTHON MOLURUS BIVITTATUS (Burmese Python). **CLUTCH SIZE.** Through instances of pet release or escape, a reproducing population of *Python molurus bivittatus*, native to Southeast Asia, has recently become established in and around Everglades National Park, Florida, USA (Snow et al. 2007. *In* Henderson and Powell [eds.], Biology of the Boas and Pythons, pp. 416–438. Eagle Mountain Publishing, Utah). On 2 March 2007, an adult female *P. m. bivittatus* (EVER 055842; SVL = 4240 mm; total length = 4710 mm; 56.69 kg) was captured near Ficus Pond (25.3749ºN, 80.8274ºW, datum: WGS 1984) in Everglades National Park, Florida, USA. This specimen contained 85 large vitellogenic follicles (44.4–53.5 mm diameter) and 7.18 kg of fat bodies. Of these follicles, 48 were located in the right ovary (weight 2.49 kg) and 37 in the left ovary (weight 1.90 kg). A previous study reports a mean clutch size for *P. m. bivittatus* in Florida of 35.75 ± 3.35 (N = 8; range 19–46; Brien et al. 2007. Herpetol. Rev. 38:342). This finding of 85 follicles marks the largest recorded clutch size for *P. m. bivittatus* found in Florida.

SALVADORA BAIRDI (Baird's Patch-nosed Snake). **DIET.** To our knowledge, no prey items have been recorded from *Salvadora bairdi*. Field guides list prey items of *S. bairdi* as amphibians, lizards, and small mammals (Díaz and Díaz 2005. Anfibios y Reptiles de Aguascalientes. CONABIO, México, Distrito Federal, México 318 pp.), and principally diurnal lizards (Uribe-Peña et al. 1999. Anfibios y Reptiles de las Serranías del Distrito Federal, México. Instituto de Biología, México, Distrito Federal, México 119 pp.). However, these accounts do not appear to be based on published records or museum specimens and lack detail. Here we report predation by *S. bairdi* on an adult field mouse (*Reithrodontomys* or *Peromyscus* sp.). On 28 May 2003, we observed a young *S. bairdi* attempting to eat an adult field mouse along a dry irrigation canal. Cornfields dominated the surrounding agricultural matrix of a broad volcanic valley at 2520 m elev. (Municipio de Atlacomulco, Estado de México, México). When encountered, the snake was holding the dead mouse in its jaws, as well as with a loose loop of its body. The rear third of the snake was hidden from sight within a rodent burrow. We attempted to hand capture the snake, however it escaped down the rodent burrow. We estimate the snake's total length to have been ca. 80 cm.

Submitted by **KIRK SETSER (**e-mail: kwsetser@gmail.com)**, ESTRELLA MOCIÑO-DELOYA**, Departamento de Biología Animal, Facultad de Ciencias, Universidad de Granada, C.P. E-18071, Granada, España; **DAVID LAZCANO**, Universidad Autónoma de Nuevo León, Facultad de Ciencias Biológicas, Laboratorio de Herpetología, Apartado Postal - 513, San Nicolás de los Garza, Nuevo León, C. P. 66450, México; and **ALAN KARDON**, San Antonio Zoological Gardens, 3903 N. St. Marys Street, San Antonio, Texas 78212, USA.

THAMNOPHIS SCALARIS (Mexican Alpine Blotched Garter Snake). **OPHIOPHAGY**. *Thamnophis scalaris* is known to eat earthworms, amphibians, lizards, and rodents, and there is a single report of predation upon a neonate *Crotalus triseratus* (Manjarrez et al. 2007. Southwest. Nat. 52:258–262).

Here we report an additional observation of ophiophagy by *T. scalaris*. One of us (MF) collected a large adult male *T. scalaris* (483 mm SVL, 102 mm tail length, tail tip missing, 67.0 g after regurgitation) on 14 July 2008 near Acambay, Estado de México, México (19.863ºN, 99.803ºW, NAD83; 2720 m elev.). Within hours of capture, this snake voluntarily regurgitated an adult male *Thamnophis scaliger* (363 mm SVL, 93 mm tail length, 32.3 g; Fig. 1) which had been ingested head first. We estimate that approximately 10–15% of the consumed snake's body mass had been lost to digestion. We released the *T. scalaris* at the capture site; the *T. scaliger* was deposited in the Colección de Anfibios y Reptiles

FIG. 1. Adult male *Thamnophis scalaris* with a recently regurgitated, partially digested adult male *Thamnophis scaliger*.

THAMNOPHIS SCALIGER (Mesa Central Blotched Garter Snake). **MAXIMUM ELEVATION**. We obtained a partially digested adult male *Thamnophis scaliger* (363 mm SVL, 93 mm tail length, 32.3 g) that was regurgitated by a *Thamnophis scalaris* collected on 14 July 2008 near Acambay, Estado de México, México (19.863ºN, 99.800ºW, NAD83) (Mociño-Deloya et al. 2009. Herpetol. Rev. 40:442–443). The *T. scaliger* was deposited in the Colección de Anfibios y Reptiles del Museo de Zoología de la Facultad de Ciencias, Universidad Nacional Autónoma de México (MZFC 22105). We observed a second male *T. scaliger* (316 mm SVL, 77 mm tail length, 22.0 g) at the same site on 24 July 2008. Both snakes were encountered in a broad, flat, montane valley lying at ca. 2720 m elev. Previous to these encounters, *T. scaliger* was known to inhabit a vertical distribution of 2288–2575 m (Rossman et al. 1996. The Garter Snakes: Evolution and Ecology. Univ. Oklahoma Press, Norman. 331 pp.). Habitat in this valley is similar to other areas where we have observed *T. scaliger* in the Estado de México, consisting of seasonally mesic grassland and agricultural fields.

Submitted by **ESTRELLA MOCIÑO-DELOYA** (e-mail: allertsemoci@yahoo.com), **KIRK SETSER, SENDA REGUERA**, **MÓNICA FERICHE,** and **JUAN M. PLEGUEZUELOS,** Departamento de Biología Animal, Facultad de Ciencias, Universidad de Granada, C.P. E-18071, Granada, España.

GEOGRAPHIC DISTRIBUTION

Instructions for contributors to Geographic Distribution appear in Volume 40, Number 1 (March 2009, p. 106). Please note that the responsibility for checking literature for previously documented range extensions lies with authors. Do not submit range extension reports unless a thorough literature review has been completed.

CAUDATA – SALAMANDERS

AMBYSTOMA OPACUM (Marbled Salamander). USA: TENNESSEE: MARSHALL CO.: (35.6700ºN, 86.7856ºW, NAD83). 21 April 2009. Michael Anderson. Verified by B. T. Miller. Numerous larvae observed in pond, one reared through metamorphosis. Deposited in the Herpetology Collection at Middle Tennessee State University (MTSU 423C). First record for county and establishes species in the interior of the Central Basin ca. 48 km from previous site in Rutherford County (Redmond and Scott 1996. Atlas of Amphibians in Tennessee. Misc. Publ. No. 12. Center for Field Biology, Austin Peay State University, Clarksville, Tennessee. 94 pp. Internet version [http://www.apsu.edu/amatlas] contains links to information regarding Tennessee distribution of amphibians recorded since 1996; accessed 21 April 2009).

Submitted by **MICHAEL A. ANDERSON** and **DANIEL ESTABROOKS,** Department of Biology, Middle Tennessee State University, Murfreesboro, Tennessee 37132, USA.

AMBYSTOMA TIGRINUM (Eastern Tiger Salamander). USA: GEORGIA: WALKER CO.: Drag Fold Cave (34.611111°N, 85.459722°W; datum NAD83). March 2009. Jonny Prouty and Brian Killingbeck. UF 155378. Verified by Kenneth L. Krysko. First county record and first Georgia record outside of the Coastal Plain. Extends range ca. 75 km SSE of nearest record (Franklin County, Tennessee; Redmond and Scott 1996. Atlas of Amphibians in Tennessee. Austin Peay State University. Misc. Publ. No. 12. 94 pp.) and 240 km NNW of nearest Georgia record (Chattahoochee Co.; Jensen et al. 2008. Amphibians and Reptiles of Georgia. University of Georgia Press, Athens. 575 pp.) One adult photographed at the bottom of the cave's vertical pit entrance, presumably after falling in.

Submitted by **JOHN B. JENSEN**, Georgia Department of Natural Resources, Nongame Conservation Section, 116 Rum Creek Dr., Forsyth, Georgia 31029, USA; e-mail: john.jensen@gadnr.org.

EURYCEA CIRRIGERA (Southern Two-Lined Salamander). USA: INDIANA: PIKE CO.: Patoka River National Wildlife Refuge and Management Area. (38.38977°N, 87.29393°W; NAD 83, Zone 16). 12 February 2009. Lindsey Landowski. Verified by Chris Phillips. Illinois Natural History Survey (INHS 2009k). This capture provides a new county record for Indiana (Minton 2001. Amphibians and Reptiles of Indiana. 2nd ed., revised. Indiana Academy of Science. vii–404 pp.). Several individuals were found near the mouth of a spring. This species was previously thought to be absent from the Wabash lowlands region of southwestern Indiana.

Submitted by **LINDSEY LANDOWSKI**, US Fish and Wildlife Service, Patoka River National Wildlife Refuge, 510 1/2 West Morton Street, P.O. Box 217, Oakland City, Indiana 47660, USA; e-mail: Lindsey_Landowski@fws.gov.

EURYCEA GUTTOLINEATA (Three-lined Salamander). USA: GEORGIA: Madison Co.: Eugene Odum Spring Hollow property, 0.6 km NE of intersection of Hudson River Church Rd. and Wesley Chapel Rd. (34.201441°N, 83.304608°W; WGS 84). 03 May 2009. Mark O. Milby and Andrew M. Durso. Verified by Kenneth L. Krysko. FLMNH 155681. New county record (Jensen et al. 2008. Amphibians and Reptiles of Georgia. University of Georgia Press, Athens. 575 pp.). An adult *E. guttolineata* was found on a log in a streambank at ca. 0815 h. This record is ca. 22.1 km NE of a 1953 record from Athens-Clarke County, Georgia (GMNH 233).

Submitted by **ANDREW M. DURSO** (e-mail: amdurso@gmail.com) and **MARK O. MILBY (**e-mail: markmilby@gmail.com), University of Georgia, Odum School of Ecology, Athens, Georgia 30602, USA.

EURYCEA LONGICAUDA MELANOPLEURA (Dark-Sided Salamander). USA: ARKANSAS: Cleburne Co.: near Heber Springs (35.45494ºN, 91.95382ºW; WGS84; elev. 103 m). 04 May 2009. Thomas J. Belford. Verified by William E. Duellman. University of Kansas Natural History Museum (KUDA 005367). Six specimens were found in a rocky draw next to a small stream. First county record (Trauth et al. 2004 The Amphibians and Reptiles of Arkansas. Univ. of Arkansas Press, Fayetteville. 421 pp.), ca. 49 km SE of nearest record in Stone County.

Submitted by **THOMAS J, BELFORD**, 701 West Academy Avenue, Searcy, Arkansas 72143, USA; e-mail: thomasbelfordinraq@yahoo.com.

EURYCEA LUCIFUGA (Cave Salamander). USA: ARKANSAS: Cleburne Co.: near Heber Springs (35.45513ºN 91.95355ºW; WGS84; elev. 126 m). 04 May 2009. Thomas J. Belford. Verified by William E. Duellman. University of Kansas Natural History Museum (KUDA 005369). Two specimens were found in a rocky draw next to a small stream. Both specimens were observed at the entrance of what appeared to be a small crevice. First county record (Trauth et al. 2004 The Amphibians and Reptiles of Arkansas. Univ. of Arkansas Press, Fayetteville. 421 pp.), ca. 56 km SE of near known record in Stone County.

Submitted by **THOMAS J, BELFORD**, 701 West Academy Avenue, Searcy, Arkansas 72143, USA; e-mail: thomasbelfordinraq@yahoo.com.

NOTOPHTHALMUS VIRIDESCENS LOUISIANENSIS (Central Newt). USA: ARKANSAS: Faulkner Co.: near Woolly Hollow State Park, 7.1 miles S of AR-65 (35.28900ºN, 92.28250ºW; WGS84; elev. 159 m). 01 Jun 2009. Thomas J. Belford . Verified by William E. Duellman. University of Kansas Natural History Museum (KUDA 007614). Single specimen was found beneath a moss covered log on the forest floor. First county record (Trauth et al. 2004 The Amphibians and Reptiles of Arkansas. Univ. of Arkansas Press, Fayetteville. 421 pp.), extending range ca. 45 km from nearest known record in Conway County.

Submitted by **THOMAS J, BELFORD**, 701 West Academy Avenue, Searcy, Arkansas 72143, USA; e-mail: thomasbelfordinraq@yahoo.com.

NOTOPHTHALMUS V. VIRIDESCENS (Red-spotted Newt). USA: OHIO: Belmont Co.: Wayne Township. Raven Rock (39.88036°N, 81.04077°W; WGS 84). 04 April 2006. Jeffrey G. Davis and Greg Lipps Jr. Cincinnati Museum Center (CMC 8957–8958). Shelby Co.: Washington Township. Lockington Preserve (40.21596ºN, 84.25667ºW; WGS 84). 12 August 2008. Jeffrey G. Davis and Greg Lipps Jr. CMC 11283. All specimens verified by John W. Ferner. New county records (Pfingsten and Matson 2003. Ohio Salamander Atlas. Ohio Biol. Surv. Misc. Contrib. No. 9, Columbus).

NOTOPHTHALMUS VIRIDESCENS (Eastern Newt). USA: INDIANA: Pike Co.: Patoka River National Wildlife Refuge and Management Area (38.34905°N, 87.12464°W; NAD 83). 15 April 2009. Angela Garcia, Sarabeth Klueh, and Alisha Maves. Verified by Chris Phillips. Illinois Natural History Survey (INHS 2009m). New county record (Minton 2001. Amphibians and Reptiles of Indiana. 2nd ed., revised. Indiana Academy of Science. vii–404 pp.).

Submitted by **ANGELA GARCIA** and **SARABETH KLUEH** (e-mail: sklueh@dnr.in.gov), Wildlife Diversity Section, Indiana Department of Natural Resources, Division of Fish and Wildlife, 553 E. Miller Drive, Bloomington, Indiana 47401, USA; **LINDSEY LANDOWSKI** (e-mail: Lindsey_Landowski@fws.gov) and **ALISHA MAVES,** US Fish and Wildlife Service, Patoka River National Wildlife Refuge, 510 1/2 West Morton Street, P.O. BOX 217, Oakland City, Indiana 47660, USA.

NOTOTRITON BRODIEI (NCN). HONDURAS: CORTÉS: Parque Nacional Cusuco, Danto Camp (15.530290ºN, 88.276323ºW; 15.514672ºN, 88.271379ºW; WGS84), 1540–1590 m elev. 6–13 July 2008. Michael Wall**.** Verified by David B. Wake. MVZ 258034–36. First records for Honduras and extends range about 50 km NE of the only other locality for this species, the type locality at Izabal, Guatemala, in the Sierra de Caral, Morales (Campbell and Smith 1998. Sci. Pap. Nat. Hist. Mus., Univ. Kansas 6:1–8). The salamanders were collected in pitfall traps located in lower montane wet forest within a remote protected region of Cusuco National Park, which may serve as a stronghold for this species barring further habitat destruction.

ANURA – FROGS

ANAXYRUS AMERICANUS (American Toad). USA: INDIANA: Sullivan Co.: Fairbanks Township: 0.74 km E of Wabash River (39.2047°N, 87.575°W; NAD 83, Zone 16). 27 April 2009. Sarabeth Klueh, Angela Garcia, and Nathan Engbrecht. Verified by Chris Phillips. Illinois Natural History Survey (INHS 2009.p). New

county record for Indiana (Minton 2001. Amphibians and Reptiles of Indiana. 2nd ed., revised. Indiana Academy of Science. vii–404 pp.). Adults were found on road. This species occurs commonly throughout most of Indiana but appears to be largely absent from a pocket of counties in the southwest part of the state (Minton, *op. cit.*). This record partially fills a gap in the range of this species in southwest Indiana.

Submitted by **SARABETH KLUEH** (e-mail: sklueh@dnr.in.gov) and **ANGELA GARCIA**, Wildlife Diversity Section, Indiana Department of Natural Resources Division of Fish and Wildlife, 553 E. Miller Drive, Bloomington, Indiana 47401, USA; and **NATHAN ENGBRECHT**, 135 Holmstedt Hall, Indiana University School of Medicine-Terre Haute, Indiana State University, Terre Haute, Indiana 47809, USA (e-mail: nengbrecht@indstate.edu).

BOMBINA ORIENTALIS (Oriental Fire-bellied Toad). REPUBLIC OF KOREA: JEJU ISLAND: Jeju Province: Hallasan National Park (33.3125361°N, 126.5493444°E; Google Earth). 15 May 2009. P. Fidenci. Verified by Hallie Brignall. California Academy of Sciences photo vouchers (CAS-HPV 55–56). First record for Jeju Island (Song 2007. A Field Guide Book of Amphibians and Reptiles in the Korean National Park. National Park Research Institute, Annual Report No. 2007-3. KNPS, Namwon. 77 pp.). Four adults observed on backwater pools along a tributary of Hallansan River.

DENDROPSOPHUS MARMORATUS. BRAZIL: MATO GROSSO: Municipality of Sinop (11.866667ºS, 55.483333ºW; datum: Córrego Alegre), Gleba Bandeirantes, Fazenda Sant'ana. October 1976. H. Cunha. Verified by S. P. de Carvalho e Silva. Departamento de Zoologia, Universidade Federal do Rio de Janeiro (ZUFRJ 10556–567). Previously known in Brazil from Marmelo (State of Rondonia) and Jacareacanga (State of Pará) (Bokermann 1964. Senck. Biol. 45:243–254). New state record, extends the range ca. 230 km S and 250 km E from localities previously known (Bokermann, *op. cit.*).

Submitted by **MARCIA DOS REIS GOMES**, Universidade Federal do Rio de Janeiro, Departamento de Zoologia, caixa postal 68.044, CEP 21944-970, Cidade Universitária, Rio de Janeiro, Brazil; and **OSWALDO LUIZ PEIXOTO**, Universidade Federal Rural do Rio de Janeiro, Instituto de Biologia, km 7, Rodovia BR 465, Seropedica, Rio de Janeiro, Brazil 23890-000 (e-mail: pedra10@yahoo.com).

GASTROTHECA PULCHRA: BRAZIL: PERNAMBUCO: Municipality of Jaqueira: Private Reserve Frei Caneca (08.722500ºS, 35.841667ºW, WGS 84, elev. 631 m). 25 October 2008. S. P. Lima dos Santos and E. Maranhão dos Santos. Verified by U. Caramaschi. Coleção Herpetologica da Universidade Federal Rural de Pernambuco, Unidade Acadêmica de Serra Talhada, Serra Talhada, Pernambuco, Brazil (CHUFRPE 970, adult specimen SVL 36.8 mm). Previously known only from the type locality: Reserve Biological of Pau Brasil (CEPLAC), Municipality of Porto Seguro, Macote, Ilheus and Itamari, State of Bahia, Brazil (Caramaschi and Rodrigues 2007. Bol. Mus. Nac., N.S., Zool., Rio de Janeiro, 525:1–19); Amargosa and Elíseo Medrado municipality, State Bahia, Brazil (Freitas et al. 2009. Herpetol. Rev. 40:233–234). First state record, extends the known distribution ca. 918 km NE from type locality and 563 km NE from Elíseo Medrado municipality.

Submitted by **SUENY PALOMA LIMA DOS SANTOS,** Universidade Federal de Pernambuco, Centro de Ciências Biológicas Av. Prof. Moraes Rego, 1235 - Cidade Universitária, 50670-901, Recife, PE, Brazil; and **EDNILZA MARANHÃO DOS SANTOS**, Unidade Acadêmica de Serra Talhada, Universidade Federal Rural de Pernambuco, 56900-000, Serra Talhada, PE, Brazil.

GASTROPHRYNE OLIVACEA (Western Narrow-mouthed Toad). USA: TEXAS: Guadalupe Co.: 160 m N intersection Old Seguin Road with Long Branch Creek, along the banks of the creek (29.792472°N, 97.93575°W, WGS84). 09 September 2009. Michael Vandewege and Amber Harper. Verified by James R.

Dixon. Texas Cooperative Wildlife Collection (TCWC 94267). One adult (19.8 mm SUL, 1.6 g) found after rains. New county record (Dixon 2000. Amphibians and Reptiles of Texas 2nd ed. Texas A&M University Press, College Station, Texas. 421 pp.).

Submitted by **MICHAEL W. VANDEWEGE** (e-mail: mike.vandewege@txstate.edu), **AMBER HARPER**, **VINCENT R. FARALLO**, and **MICHAEL R.J. FORSTNER**, Department of Biology, Texas State University, San Marcos, Texas 78666, USA (e-mail: MF@txstate.edu).

HYLA CINEREA (Green Treefrog). USA: ARKANSAS: CLEBURNE CO.: Dry Mountain Road 0.78 miles NW of Wilburn (35.51588ºN 91.89280ºW; WGS84; elev. 105 m). 04 May 2009. Thomas J. Belford. Verified by William E. Duellman. University of Kansas Natural History Museum (KUDA 005371). Adult specimen was found on the roadside during a thunderstorm. First county record (Trauth et al. 2004. The Amphibians and Reptiles of Arkansas. Univ. of Arkansas Press, Fayetteville. 421 pp.), extending range ca. 22.8 km from nearest record in White County.

Submitted by **THOMAS J, BELFORD**, 701 West Academy Avenue, Searcy, Arkansas 72143, USA; e-mail: thomasbelfordini raq@yahoo.com.

KALOULA PULCHRA (Asian Painted Frog). PHILIPPINES: PALAWAN ISLAND: Municipality Puerto Princesa: Barangay, Bancao Bancao (9.734425°N, 118.7648528°E; Google Earth). 05 February 2007. P. Fidenci. Verified by Hallie Brignall. California Academy of Sciences photo vouchers (CAS-HPV 57–59). First record for Palawan Island. Known records for the Philippines in Luzon (Diesmos et al. 2006. J. Env. Sci. Manage. Philippines 9:41–53). 36 adults and 11 metamorphs observed at night along ditches and grassland in Puerto Princesa City. Introduced species in the Philippines.

Submitted by **PIERRE FIDENCI**, Endangered Species International, 79 Brady St., San Francisco, California 94108, USA; e-mail: pfidenci@endangeredspeciesinternational.org.

LITHOBATES* (=*RANA*) *BLAIRI (Plains Leopard Frog). USA: INDIANA: VIGO CO.: 3.8 km SW of Prairieton (39.358909°N, 87.516249°W; NAD 83). 16 October 2008. Nathan Engbrecht and John Crawford. Verified by Chris Phillips. Illinois Natural History Survey (INHS 2009.n.). New county record (Minton 2001. Amphibians and Reptiles of Indiana. 2nd ed., revised. Indiana Academy of Science. 404 pp.) Captured in minnow trap. *Lithobates blairi* is currently listed as a species of special concern in Indiana, but is a candidate for being listed as a state endangered species (Indiana DNR Amphibian and Reptile Technical Advisory Committee-2008). Occurrence records for *L. blairi* in Indiana are scarce with only five vouchered localities (Minton, *op. cit.).* This represents the first documented occurrence of this species in Indiana since 1978 and extends the current known range of the species eastward in west-central Indiana.

Submitted by **NATHAN J. ENGBRECHT** (e-mail: nengbrecht@indstate.edu), **JOHN A. CRAWFORD**, and **MICHAEL J. LANNOO**, Indiana University School of Medicine-TH, Holmstedt Hall, Rm 135, Terre Haute, Indiana 47809, USA.

LITHOBATES YAVAPAIENSIS (Yavapai Leopard Frog). MÉXICO: CHIHUAHUA: Municipio de Temosachi: 1) along Río Tutuaca at Rancho Nogal, 16.5 air km N Yepachi (28.56134°N, 108.35596°W to 28.56887°N, 108.36528°W; WGS84), 1640 m elev. 14 June 2006. MSB 75152–153 (two adults); MSB 75148–151 (four post-metamorphic individuals, 27–31 mm SUL); MSB 75124 (lot of five tadpoles). 7.7 road km N Yepachi, tributary to Río Yepachi (28.47368°N, 108.38462°W; WGS84), 1729 m elev. 15 June 2006. MSB 75125 (lot of four pre-metamorphic tadpoles. R. D. Jennings and C. W. Painter. All verified by Mike Sredl. First records from Chihuahua (Lemos-Espinal and Smith 2007. Anfibios y Reptiles del Estado de Chihuahua, México. Univ. Nac. Autón. de México; Comis. Nac. Conoc. y Uso de la Biodiv., México, D.F. xiii + 613 pp.). Specimens were found in backwater habitats and in off-channel pools. Specimens were collected under authority of Mexico's Secretaría De Medio Ambiente y Recursos Naturales Permit SGPA/DGVS/01442/06.

Submitted by **RANDY D. JENNINGS**, Western New Mexico University, P.O. Box 680, Silver City, New Mexico 88062, USA (e-mail: jenningsr@wnmu.edu); and **CHARLES W. PAINTER,** New Mexico Department of Game and Fish, One Wildlife Way, P.O. Box 25112, Santa Fe, New Mexico 87507, USA (e-mail: charles.painter@state.nm.us).

PHASMAHYLA GUTTATA. BRAZIL: ESPÍRITO SANTO: Municipality of Atílio Vivacqua: Serra das Torres (21.001194°S, 41.216472°W; WGS84, elev. 600 m). J. C. F. Oliveira, L. Coco, F. F. de Deus, R. Pagotto, and E. S. da Silva. 10 June 2009. Verified by J. P. Pombal Jr and D. Baêta. Museu Nacional, Rio de Janeiro (MNRJ 58975). This species, endemic to the Brazilian Atlantic Rainforest, was previously known to range from Morretes (25.476944ºS, 48.833889ºW) in the state of Paraná to Santa Maria Madalena (21.878611ºS, 41.903889ºW) in the state of Rio de Janeiro (Cruz et al. 2008. S. Am. J. Herpetol. 3:187–195). The present note provides the first record for the state of Espírito Santo and the northernmost for the species, extending its distribution ca. 120 km N from Santa Maria Madalena.

Submitted by **JANE C. F. OLIVEIRA, LIVIA COCO, FLÁVIO F. DE DEUS, RENATA PAGOTTO, ELIEL SOARES DA SILVA, CARLOS FREDERICO D. ROCHA,** and **DAVOR VRCIBRADIC,** Departamento de Ecologia, Universidade do Estado do Rio de Janeiro, Rua São Francisco Xavier 524, Maracanã, 20550-011, Rio de Janeiro, RJ, Brazil.

PHYSALAEMUS SIGNIFER (Octavio's Robber Frog). BRAZIL: ESPÍRITO SANTO: Matilde, municipality of Alfredo Chaves (20.330306ºS, 40.480560ºW; datum: Córrego Alegre; 632 m elev.). 22 July 2008. R. B. Dantas. Verified by G. M. Prado. Zoology Collection, Museu de Biologia Mello Leitão, Santa Teresa, Espírito Santo, Brazil (MBML 6736–39). Previously known from the states of Bahia, Rio de Janeiro, and São Paulo (Bokermann 1962. An. Acad. Brasil. Cienc. 34:563–568; Cochran 1955. Bull. U.S. Natl. Mus. 206:351; Silvano and Pimenta CD-ROM, Ilhéus, IESB/CI/CABS/UFMG/UNICAMP; Wogel et al. 2002. Iheringia, Sér. Zool. 92[2]). First state record extends range ca. 317 km N from Saquarema municipality, Rio de Janeiro state (Wogel et al., *op. cit.*) and ca. 612 km S from Una municipality, Bahia state (Silvano and Pimenta, *op. cit.*).

Submitted by **RODRIGO BARBOSA FERREIRA,** Museu de Biologia Mello Leitão, Av. José Ruschi, N 4, CEP 29.650-000, Santa Teresa – Espírito Santo, Brazil (e-mail: rodrigoecologia@yahoo.com.br); **ROBERTO DE BARROS DANTAS,** Museu de Biologia Mello Leitão, Av. PSEUDACRIS ORNATA (Ornate Chorus Frog). USA: ALABAMA: Lowndes Co.: Chorus of calling males recorded at flooded vernal pool in pasture, 0.37 km S. of Lowndes County Rd. 40, 3 km N of White Hall (32.324712°N, 86.700823°W; WGS 84). 10 January 2009. S. Graham and K. Gray. Verified by Craig Guyer. AHAP-D 198 (audio file). New county record. This record fills a distribution gap for this species, and is approximately equidistant between historical localities for this species to the south in Butler Co. (~ 70 km), to the east in Macon Co. (~ 100 km), and to the north in Bibb and Chilton counties (~ 80 km; Mount 1975. Amphibians and Reptiles of Alabama. Auburn University Agricultural Experiment Station, Auburn Printing Co., Auburn, Alabama. 347 pp.).

Submitted by **SEAN P. GRAHAM** and **KATHERINE M. GRAY**, Department of Biological Sciences, 331 Funchess Hall, Auburn University, Alabama 36849, USA (e-mail: grahasp@auburn.edu).

RANITOMEYA BIOLAT (Bamboo Poison Frog). BRAZIL: ACRE: Open forest with bamboo (*Guadua weberbaueri*) in Fazenda Experimental Catuaba "Plot Control" (10.0822ºS, 67.06258º W; datum WGS84, elev. 180 m). 10 February 2005. P. R. Melo Sampaio. Verified by R. Schulte. Herpetological Collection, Universidade Federal do Acre, Rio Branco, Acre, Brazil (UFAC 4157–58). These specimens were found in leaf litter in "tabocal" habitat, 0800–1100 h. Species previously known from the Tambopata Region, Madre de Dios, Peru (Doan and Arriaga 2002. Biotropica 34[1]:101–117; Morales 1992. Carib. J. Sci. 28[3–4]:191–199; Waldram 2008. J. Herpetol. 42:232–237) and Department of Pando, Bolivia (Maldonado and Reichle 2007. Kempffiana 3[1]:14–17). First country record, extends the known distribution ca. 450 km NE from type locality in Peru (Morales, *op. cit.*)

Submitted by **PAULO ROBERTO MELO SAMPAIO**, Laboratório de Herpetologia (HerPet), Universidade Federal do Acre, BR-364 km 04, Campus Universitário Áulio Gélio Alves de Souza, Distrito Industrial, CEP: 69.915-900, Rio Branco, Acre, Brazil (e-mail: herpeton@gmail.com); and **MOISÉS BARBOSA DE SOUZA**, Universidade Federal do Acre - Centro de Ciências Biológicas e da Natureza (CCBN), BR-364 km 04, Campus Universitário Áulio Gélio Alves de Souza, Distrito Industrial, CEP: 69.915-900, Rio Branco, Acre, Brazil (e-mail: moisebs@terra.com.br).

RHACOPHORUS BIPUNCTATUS (Twin-spotted Tree Frog). BANGLADESH: HABIGANJ DISTRICT: Satchari National Park (24.1166667ºN, 91.4166667ºE; 195–210 m elev.). 06 March 2009. Sharif A. Mukul. Verified by Guin Wogan. Digital image deposited at USDZ, Raffles Museum of Biodiversity Research, National University of Singapore (ZRC [IMG] 1.29). Taxonomy revised (see Bordoloi et al. 2007. Zootaxa 1653:9) since first report from country as *R. htunwini* (Chakma 2007. Herpetol. Rev. 38:478). First verified record for Sylhet Division (northeastern evergreen forests). Nearest population reported from Kaptai National Park, Chittagong Division, > 200 km S of present locality (Chakma 2007, *op. cit.*). Nearest extraterritorial records include Assam (Bordoloi et al. 2007, *op. cit.*; ~ 300 km N), Nagaland (Ao et al. 2003. Zoo's Print J. 18:1124; > 500 km NE), Manipur (Devi and Singh 2006. J. Exp. Zool. India 9:317–324; ~ 400 km E) in India, and Rakhine State (Wilkinson et al. 2005. Proc. California Acad. Sci. 56[4]:42–52; ~ 1200 km S) in Myanmar. Adult found before sunset on forested trail, ca. 1.5 km from old Dhaka-Sylhet highway, and heavily used for firewood collection by local villagers. Habitat includes several *Acacia* plantations with major undergrowth of *Phrynium*, *Lantana*, *Amomum*, *Mikenia*, and *Macaranga*.

Submitted by **A. H. M. CHELUS FIMBRIATUS (Matamata Turtle). BRAZIL: AMAZONAS: Santa Isabel do Rio Negro (0.3335º S; 65.3116º W; WGS84). Collected in Jaradi River with trammel nets. 18 Jan 2006. L. Schneider, R. C. Vogt, L. B. Santos-Junior, C.R. Ferrara. Verified by L. Bonora. Coleção de Repteis e Anfibios, Instituto Nacional de Pesquisas da Amazonia, Manaus, Amazonas, Brazil (INPAH 18506 and 18507). *Chelus* ranges throughout the Orinoco and Amazon River basins of Venezuela, Colombia, Ecuador, Peru, northern Bolivia, Surinam, French Guiana, and Brazil (Vogt 2008. Amazon Turtles. Grafica Biblos, Lima, Peru. 104 pp.). The nearest locality record is at the mouth of Rio Branco (1.468ºS; 61.548ºW; WGS84), on the border of Amazonas State and Roraima State, 400 km to the southeast (Hartline 1967; cited in Pritchard and Trebbau 1984. The Turtles of Venezuela. Society for the Study of Amphibians and Reptiles, Oxford, Ohio. 403 pp.). The present record for the Jaradi River, in the upper Rio Negro Basin, begins to fill in the 331,662 km^2 gap in the distribution between San Gabriel de Cachoeira, Brazil and the hydrographic basin of Venezuela and Guyana.

Submitted by **LARISSA SCHNEIDER** (e-mail: laribio@terra.com.br), **RICHARD C. VOGT**, **LADISLAU B. SANTOS-JUNIOR,** and **CAMILA R. FERRARA**, Instituto Nacional de Pesquisas da Amazônia (INPA), Caixa Postal 478, CEP 69011-970, Manaus, Amazonas, Brazil.

CHELYDRA SERPENTINA SERPENTINA (Eastern Snapping Turtle). USA: TEXAS: Hidalgo Co.: Male turtle (7.6 kg) captured in a pond at Frontera Audubon (26.14691°N, 97.98856°W; NAD 83). 30 May 2009. Brian E. Dickerson, Amanda D. Schultz, and Donald J. Brown. Verified by Toby Hibbits. Texas Cooperative Wildlife Collection (TCWC 93912), Texas A&M University. MRJF observed a *Chelydra s. serpentina* in Harlingen, Texas in 1983 but was unable to capture the turtle. During preparation for this record we were informed that additional *Chelydra* have been observed in the last ten years from both Hidalgo and Cameron counties (P. Burchfield, pers. comm.). Although the potential for anthropogenic dispersal cannot be ignored, in context, this individual and the other reports of this species in the area are evidence of an established wild population in extreme south Texas. Historically, the lack of surface water south of the Nueces River would likely have provided a barrier to dispersal for the species. However, modern drainage and livestock pond systems in this area are now very extensive. Trapping was conducted for the Texas Parks and Wildlife Department freshwater turtle assessment (permit SPR-0102-191). New county record (Dixon 2000. Amphibians and Reptiles of Texas. 2nd Edition. Texas A&M Univ. Press, College Station, 421 pp.).

FORSTNER (**e-mail: mf@txstate.edu), Department of Biology, Texas State University-San Marcos, San Marcos, Texas 78666, USA; and **JAMES R. DIXON**, Department of Wildlife and Fisheries Sciences, Texas A&M University, College Station, Texas 77843, USA.

CHRYSEMYS PICTA (Painted Turtle). USA: GEORGIA: Wilkes Co.: Washington, Newtown Road, 1.6 km N Jane Hill Road

(33.84235°N, 82.81744°W, WGS84; elev. 138 m). 23 April 2009. Justin T. Oguni. Verified by Kenneth L. Krysko. Florida Museum of Natural History (photographic voucher UF 155280). New county record (Jensen et al. 2008. Amphibians and Reptiles of Georgia. University of Georgia Press, Athens. 575 pp.). Found AOR at 1636 h over a creek surrounded by undeveloped forest adjacent to cattle pastures.

Submitted by **JUSTIN T. OGUNI**, College of Veterinary Medicine, University of Georgia, Athens, Georgia 30602, USA; e-mail: goonie16@gmail.com.

CUORA AMBOINENSIS (Malayan Box Turtle). PHILIPPINES: BATAS ISLAND: Palawan Province: Taytay Municipality: along unnamed creek (11.1810028°N, 119.6140111°E; Google Earth). 02 March 2008. P. Fidenci. Verified by Hallie Brignall. California Academy of Sciences photo vouchers (CAS-HPV 60–61). First records for Batas Island (Diesmos et al. 2008. Chelon. Conserv. Biol. 7:157–177). Six adults observed along seasonal creek.

Submitted by **PIERRE FIDENCI**, Endangered Species International, 79 Brady St., San Francisco, California 94103, USA; e-mail: pfidenci@endangeredspeciesinternational.org.

GRAPTEMYS GEOGRAPHICA (Northern Map Turtle). USA: NORTH CAROLINA: Cherokee Co.: 7.6 km WSW of Violet, Hiwassee River below Apalachia Lake Dam, just E of Tennessee state line (35.1681°N, 84.2959°W, WGS84). 22–23 June 2009. Jeffrey C. Beane, L. Todd Pusser, and Robert A. Davis. Verified by William M. Palmer. North Carolina State Museum of Natural Sciences (NCSM 75934, 75935, 75943 [3 males collected 22 June 2009]; 75936 [female collected 23 June 2009]; several additional individuals were observed and photographed]. New county record and first vouchered records for North Carolina (Palmer and Braswell 1995. Reptiles of North Carolina. University of North Carolina Press, Chapel Hill. 412 pp.). Extends range ca. 32 km ENE and ca. 42 km SSE of nearest records in Georgia and Tennessee, respectively (Iverson 1992. A Revised Checklist with Distribution Maps of Turtles of the World. Privately published, Richmond, Indiana. xiii + 363 pp.; Jensen et al. [eds.] 2008. Amphibians and Reptiles of Georgia. University of Georgia Press, Athens. xviii + 575 pp.).

We thank Gabrielle J. Graeter and Kendrick C. Weeks of the North Carolina Wildlife Resources Commission for assistance in documenting this population, and the Tennessee Valley Authority for allowing access to their reservations.

Submitted by **JEFFREY C. BEANE**, North Carolina State Museum of Natural Sciences, Research Laboratory, MSC# 1626, Raleigh, North Carolina 27699-1626, USA (e-mail: jeff.beane@ncdenr.gov); **L. DAVIS**, 11320 Peed Dead End Road, Raleigh, North Carolina 27614, USA (e-mail: radavis413@msn.com).

KINOSTERNON SUBRUBRUM (Eastern Mud Turtle). USA: GEORGIA: Madison Co.: Eugene Odum Spring Hollow property impoundment, 0.45 km NE of intersection of Hudson River Church Rd. and Wesley Chapel Rd. (34.200065°N, 83.304924°W; WGS 84). 02 May 2009. Andrew M. Durso. Verified by Kenneth L. Krysko. Florida Museum of Natural History (FLMNH 155676). New county record (Jensen et al. 2008. Amphibians and Reptiles of Georgia. University of Georgia Press, Athens. 575 pp.). An adult *K. subrubrum* was captured in a hoop trap baited with canned sardines in soybean oil. This record is ca. 22.1 km NE of a 1952 record from Athens-Clarke County, Georgia (GMNH 39).

Submitted by **ANDREW M. DURSO**, University of Georgia, Odum School of Ecology, Athens, Georgia 30602, USA; e-mail: amdurso@gmail.com.

KINOSTERNON SUBRUBRUM (Eastern Mud Turtle). USA: GEORGIA: Wilkes Co.: Washington, Newtown Road, 1.6 km N Jane Hill Road (33.84235°N, 82.81744°W, WGS84; elev. 138 m). 28 April 2009. Justin T. Oguni. Verified by Kenneth L. Krysko. Florida Museum of Natural History (photographic voucher UF 155279). New county record (Jensen et al. 2008. Amphibians and Reptiles of Georgia. University of Georgia Press, Athens. 575 pp.). Found AOR at 1636 h over a creek surrounded by undeveloped forest adjacent to cattle pastures.

Submitted by **JUSTIN T. OGUNI**, College of Veterinary Medicine, University of Georgia, Athens, Georgia 30602, USA; e-mail: goonie16@gmail.com.

RHINOCLEMMYS PUNCTULARIA (Spot-legged Turtle). BRAZIL: PARÁ: Porto de Moz. Approximately 3 km from the Xingu River in chácara do Elias (02.18194ºS, 52.2861ºW; WGS84). Captured on the forest floor at 1030 h. 02 Dec 2008. L. Schneider, A. A. Kuniy, R. C. Vogt. Verified by E. Hingst Zaher. Coleção de Repteis e Anfibios, Museu de Zoologia da Univesidade de São Paulo, Sao Paulo, Brazil (MZUSP 4365). The known range of this species is concentrated along the coastal plain of Venezuela, the Guianas, and northern Brazil to the state of Maranhão (Rueda-Almonacid et al. 2007. Las Tortugas y los Crocodilianos de los Países Andinos del Trópico. Serie de Guías Tropicales de Campo 6. Conservación Internacional. Editora Panamericana, Formas e Impresos. Bogotá, Colombia, 538 pp.). This is the first record for the Xingú basin, the fourth largest drainage of the Amazon Basin (Vogt 2008. Tartarugas da Amazônia, Grafica Biblos, Lima, Peru. 104 pp.). The closest previous record (MZUSP 2207) was in Corcovado, Pará (51.65ºS, 50.008ºW; WGS84) (Pritchard and Trebbau 1984. The Turtles of Venezuela. Society for the Study of Amphibians and Reptiles, Oxford, Ohio. 403 pp.). This new record extends the range for this species 360 km S in the Amazon Basin.

Submitted by **LARISSA SCHNEIDER** (e-mail: laribio@terra.com.br), **ADRIANA A. KUNIY**, and **RICHARD C. VOGT**, Instituto Nacional de Pesquisas da Amazônia (INPA), Caixa Postal 478, CEP 69011-970, Manaus, Amazonas, Brazil.

STERNOTHERUS ODORATUS (Eastern Musk Turtle). USA: GEORGIA: Madison Co.: Eugene Odum Spring Hollow property impoundment, 0.45 km NE of intersection of Hudson River Church Rd. and Wesley Chapel Rd. (34.200065°N, 83.304924°W; WGS 84). 02 May 2009. Andrew M. Durso. Verified by Kenneth L. Krysko. Florida Museum of Natural History (FLMNH 155677–155678. New county record (Jensen et al. 2008. Amphibians and Reptiles of Georgia. University of Georgia Press, Athens. 575 pp.). An adult *S. odoratus* was captured in a hoop trap baited with canned sardines in soybean oil. Additionally, a juvenile *S. odoratus* was captured in an unbaited minnow trap. These records are ca. 12.1 km NE of

a 2000 record from Jackson County, Georgia (GHA 04242).

Submitted by **ANDREW M. DURSO**, University of Georgia, Odum School of Ecology, Athens, Georgia 30602, USA; e-mail: amdurso@gmail.com.

STERNOTHERUS ODORATUS (Eastern Musk Turtle). USA: OHIO: GALLIA CO.: Raccoon Township. Tycoon Lake Wildlife Area (38.92051ºN, 82.35867ºW; WGS 84). 03 June 2001. Jeffrey G. Davis and Paul J. Krusling. Verified by John W. Ferner. Cincinnati Museum Center (CMC 11022). New county record (Wynn and Moody 2006. Ohio Turtle, Lizard, and Snake Atlas. Ohio Biol. Surv. Misc. Contrib. No. 10, Columbus).

Submitted by **JEFFREY G. DAVIS (**e-mail: anura@fuse.net) and **PAUL J. KRUSLING (**e-mail: pkrusling@fuse.net), Cincinnati Museum Center – Fredrick and Amye Geier Research and Collections Center, 1301 Western Avenue, Cincinnati, Ohio 45203-1130, USA.

TRACHEMYS SCRIPTA (Pond Slider Turtle). USA: GEORGIA: ELBERT CO.: Elberton, SR 79, 0.72 km S Cooter Creek Road (33.98314ºN, 82.63454ºW; WGS84; elev. 127 m). 28 April 2008. Justin T. Oguni. Verified by Kenneth L. Krysko. Florida Museum of Natural History (photographic voucher UF 155281). New county record (Jensen et al. 2008. Amphibians and Reptiles of Georgia. University of Georgia Press, Athens. 575 pp.). Found AOR at 1650 h in undeveloped forest.

Submitted by **JUSTIN T. OGUNI**, College of Veterinary Medicine, University of Georgia, Athens, Georgia 30602, USA; e-mail: goonie16@gmail.com.

SQUAMATA – LIZARDS

ABRONIA DEPPEI (Deppe's Arboreal Alligator Lizard). MÉXICO: MICHOACÁN: Municipality of Zitacuaro: Molcajete Mountain, 3 km S of Lazaro Cardenas (19.3946°N, 100.3586°W; WGS84), 2360 m elev. Eric Centenero Alcalá. Verified by Uri García Vázquez. Museo de Zoología Luis Herrera de la Facultad de Ciencias de la UNAM (MZFC 22673). First state record for genus and species, extending the known range ca. 34 km W from Valle de Bravo, México (Flores-Villela and Sanchez-Herrera 2003. Herpetologica 59:524–531). The specimen was found on a tree in oak forest

Submitted by **ERIC CENTENERO-ALCALÁ**, Laboratorio de Ecología, Unidad de Biotecnología y Prototipos, Facultad de Estudios Superiores Iztacala, Universidad Nacional Autónoma de México. Av. de los Barrios s/n, Los Reyes Ixtacala, Tlalnepantla, México, C.P. 54090 (e-mail: eca_46@hotmail.com); **VÍCTOR HUGO JIMÉNEZ-ARCOS**, Laboratorio de Herpetología, Instituto de Biología, Universidad Nacional Autónoma de México. 3er Circuito exterior s/n, Ciudad Universitaria, Coyoacán, México, D.F. ANOLIS INSIGNIS (Giant Banded Anole). COSTA RICA: GUANACASTE: Trail to top (Sendero Derrumbe) of Cerro Cacao (10.929166°N, 85.466016°W; WGS84), 1270 m. elev. 13 March 2009. G. Köhler and J. Sunyer. Verified by Sebastian Lotzkat. Senckenberg Forschungsinstitut und Naturmuseum (SMF 89790). Northwesternmost record within the known range of this species, with the closest reported locality being near Bijagua, ca. 50 km to the southeast (Savage and Talbot 1978. Copeia 1978:480–492; Savage 2002. The Amphibians and Reptiles of Costa Rica. Univ. Chicago Press, Chicago, Illinois. 934 pp.). The lizard was found in an area containing premontane moist forest.

Submitted by **GUNTHER KÖHLER** and **JAVIER SUNYER,** Senckenberg Forschungsinstitut und Naturmuseum, Senckenberganlage 25, 60325 Frankfurt a.M., Germany (e-mail: gkoehler@senckenberg.de).

ANOLIS NEBULOSUS (Clouded Anole). MÉXICO: GUANAJUATO: Municipality of Yuriria: Cerro La Angostura (20.28083ºN, 101.10805ºW; WGS84), 1824 m elev. 22 May 2006. Marina Sánchez Luna and Adriana J. González Hernández. Verified by Adrian Nieto Montes de Oca. Colección Nacional de Anfibios y Reptiles, Instituto de Biología, Universidad Nacional Autónoma de México (IBH 21960–64). First state records, extending the range of the species 146.5 km NE from closest known locality at Nuevo Urecho, Michoacán (González and Garza 2006. *In* Ramírez-Bautista et al. [eds.], Inventarios Herpetofaunísticos de México: Avances en el Conocimiento de su Biodiversidad, pp. 140–151. Publ. Soc. Herpetol. Mexicana No. 3, México, D.F.). The lizards were found on trees in remnant tropical deciduous forest. Field work was supported by Fondos Mixtos de Conacyt-Concyteg, grant number 04-07-A-051.

Submitted by **MARINA SÁNCHEZ-LUNA**, Facultad de Agrobiología, Universidad Autónoma de Tlaxcala, Carretera Autopista Tlaxcala-San Martin, San Felipe Ixtacuixtla, Tlaxcala, México; and **ADRIANA J. GONZÁLEZ-HERNÁNDEZ, ELISA CABRERA-GUZMÁN**, and **VÍCTOR H. REYNOSO (**e-mail: vreynoso@ibiologia.unam.mx), Colección Nacional de Anfibios y Reptiles, Instituto de Biología, Departamento de Zoología, Universidad Nacional Autónoma de México, Circuito Exterior Ciudad Universitaria, México D.F., C.P. 04510.

ANOLIS PORCATUS (Cuban Green Anole). ARUBA: Radisson Aruba Resort in southwest Aruba (12.56864ºN, 70.04664ºW; WGS84). 18 January 2009. R. Andrew Odum and Facundo Franken. Verified by Gregory Schneider. University of Michigan Museum of Zoology (UMMZ 239619). First record for Aruba (van Buurt 2006. Applied Herpetol. 3:307–321) and was most likely introduced from Cuba with a shipment of palm trees during construction of the resort. It was found in garden vegetation along with numerous other adults and juveniles, indicating an established population.

Submitted by **R. ANDREW ODUM**, Toledo Zoological Society, Toledo, Ohio 43614, USA (e-mail: Andrew.Odum@toledozoo.org); and **GERARD VAN BUURT**, Curacao, Netherlands Antilles (e-mail: gvanbuurt@gmail.com).

ASPIDOSCELIS SEXLINEATA (Six-lined Racerunner). USA: NEBRASKA: STANTON CO.: 3.2 km S, 4.8 mi E Stanton (41.9279°N, 97.1661°W; NAD83). 14 July 2008. Greg D. Wright and Keith Geluso. Verified by Travis Taggart. Sternberg Museum of

Natural History (MHP 14308, photographic voucher). First county record. Represents a 72 km range extension into northeastern Nebraska from records reported from Platte County (Lynch 1985. Trans. Nebraska Acad. Sci. 13:33–57; University of Nebraska State Museum, Lincoln, UNSM ZM 3265–3266).

Submitted by **GREG D. WRIGHT** and **KEITH GELUSO (**e-mail: gelusok1@unk.edu), Department of Biology, University of Nebraska—Kearney, Kearney, Nebraska 68849, USA.

CALOTES EMMA (Spiny-headed Forest Lizard). BANGLADESH: HABIGANJ DISTRICT: Satchari National Park (24.1166667ºN, 91.4166667ºE; no datum available; 195–210 m elev.). 08 May 2009. Sharif A. Mukul. Verified by Aaron M. Bauer. Photograph deposited at USDZ, Raffles Museum of Biodiversity Research, National University of Singapore (ZRC [IMG] 2.101). First verified locality for Habiganj District. Cited for Bangladesh with a possibility of misidentification with *C. jerdoni* (Ahsan 1998. Proceeding of the International Conference on the Biology and Conservation of the Amphibians and Reptiles of South Asia, Sri Lanka, pp. 9–17). Mentioned in a herpetofaunal checklist without voucher specimen, photograph, or locality information (Khan 2004. Cobra 57:1–31). Nearest record outside Bangladesh is from Dampa Tiger Reserve (~100 km southeast) in Mizoram, India (Pawar and Birand 2001. A Survey of Amphibians, Reptiles, and Birds in Northeast India. CERC Tech. Rep. No. 6, Centre for Ecological Research and Conservation, Mysore, India). An adult and a juvenile found preying on ants in a *Tectona grandis* plantation with a mixture of *Artocarpus chaplasha*, *A. lakoocha*, and *Ficus* sp. vegetation. Undergrowth includes *Calamus*, *Lantana*, *Mikenia*, *Micromelum*, and *Alpinia*. A preserved specimen (CAS 94323) in California Academy of Sciences was collected from Lawachara Forest under Moulvibazar District (~50 km northeast) in 1961, which has been overlooked for many years (IUCN 2000. Red Book of Threatened Amphibians and Reptiles of Bangladesh. Dhaka, Bangladesh. 95 pp.).

Submitted by **A. H. M. ALI REZA**, Department of Natural Resources Management, Texas Tech University, Lubbock, Texas 79409, USA & Department of Zoology, Jahangirnagar University, Dhaka 1342, Bangladesh (e-mail: wild_reza@yahoo.com); and **SHARIF A. MUKUL**, Department of Forestry and Environmental Science, Shahjalal University of Science and Technology, Sylhet 3114, Bangladesh (e-mail: sharif_a_mukul@yahoo.com).

COLEONYX ELEGANS (Yucatan Banded Gecko). MÉXICO: PUEBLA: Municipality of Coyuca de Andrade: El Sauce (98.1088°N, 18.4289°W, WGS 24), 1693 m elev. 6 October 2007. Carlos Hernández Jiménez. Verified by Edmundo Perez Ramos. Museo de Zoología, Facultad de Ciencias, Universidad Nacional Autónoma de México (MZFC ID1613). First record for municipality and second from Puebla, extending the known range in the state ca. 53 km (airline) from Huehuetlan el Chico (Canseco-Marquez et al. 2006. Herpetol. Rev. 37:495). The lizard was found in tropical deciduous forest.

Submited by **CARLOS A. HERNÁNDEZ-JIMÉNEZ** (e-mail: acaltetepon22@gmail.com); and **URI OMAR GARCÍA VÁZQUEZ**, Museo de Zoología, Facultad de Ciencias, Universidad Nacional Autónoma de México, A.P. 70-399. México, D.F. 04510, México.

CTENOSAURA ACANTHURA (Northeastern Spinytail Iguana). GUATEMALA: HUEHUETENANGO: Municipio de Nentón: Miramar, Finca El Zapotál (15.89722°N, 91.787222°W; WGS84), 700 m elev. 21 November 2007. M. Acevedo and Q. Dwyer. Verified by Enio Cano. Colecciones Zoológicas de Referencia, Museo de Historia Natural, Universidad de San Carlos de Guatemala (MHN-USAC 1130). First verified record for Guatemala, with the closest known localities being in adjacent Chiapas, México (Köhler 2008. Reptiles of Central America, 2nd ed. Herpeton, Verlag E. Köhler, Offenbach, Germany. 400 pp.). The previous record from Guatemala from the same general area reported herein, listed by Acevedo (2006. *In* E. Cano [ed.], Biodiversidad de Guatemala, Vol. 1, pp. 487–524. Univ. del Valle, Ciudad de Guatemala, Guatemala) was a sight record with no voucher specimen. The lizard was found in an area containing subtropical dry forest.

Submitted by **MANUEL ACEVEDO**, Centro de Documentación para la Conservación/Centro de Estudios Conservacionistas (CDC/CECON), Universidad de San Carlos de Guatemala, Avenida Reforma 0-63 zona 10, Ciudad de Guatemala, Guatemala (e-mail: manuelaceved@gmail.com); **MILAN VESELÝ**, Dept. HEMIDACTYLUS FLAVIVIRIDIS (Yellow-green House Gecko). INDIA: ASSAM: Kamrup District: Guwahati city: Arya Vidyapeeth College Zoological Museum (AVC) A0927. Fancy Bazar (26.1911944ºN, 91.7386139ºE; no datum available; 58 m elev.); AVC A0928, Gorchuk (26.1211944ºN, 91.7355278ºE; 47 m elev.). AVC A0929. Christanbasti (26.1593611ºN, 91.7865278ºE; 36 m elev.). J. Purkayastha. 2009. Verified by A. Das. Distributed throughout northern India and westwards, not extending to east of Bengal (Smith 1935. The Fauna of British India, Ceylon and Burma, Including the Whole of the Indo-Chinese Region. Vol. III. Sauria. Taylor and Francis, London. xiii + 440 pp + 1 pl.). Occurs exclusively in commercial sites, apparently through transportation.

First record for Assam State. High density in Fancy Bazar area appears to have adverse effect on *H. frenatus* population locally.

Submitted by **JAYADITYA PURKAYASTHA** and **MADHURIMA DAS**, Zoology Department (Herpetological Lab), Arya Vidyapeeth College, Guwahati 781 016, Assam, India; e-mail: sjaya_ditya@rediffmail.com

HEMIDACTYLUS FRENATUS (Common House Gecko). HONDURAS: ISLAS DE LA BAHIA: Cayo Cochino Pequeño (15.952261ºN, 86.499075ºW; WGS84), 1 m elev. 28 December 2008. P. J. Muelleman. Verified by Robert Powell. MPM Herp Photos P741–P743. First record for Cayo Cochino Pequeño (McCranie et al. 2005. Amphibians and Reptiles of the Bay Islands and Cayos Cochinos, Honduras. Bibliomania, Salt Lake City, Utah. xiv + 210 pp.). The closest record for this species, on Cayo Cochino Grande, was accounted for in an unpublished report submitted to the Honduran Coral Reef Foundation (HCRF) by Ferrari in 2002. The lizard was found clinging to a tree adjacent to the HCRF helicopter landing pad. We thank HCRF and Operation Wallacea for supporting our Cayos Cochinos herpetological research.

Submitted by **PETER J. MUELLEMAN (**e-mail: pjm563@truman.edu) and **CHAD E. HEMIDACTYLUS MABOUIA (Wood Slave). USA: FLORIDA: St. Lucie Co.: Fort Pierce, 2100 Elizabeth Avenue (27.40840ºN, 80.34595ºW). 11 May 2009. Ken Hibbard. Verified by Kenneth L. Krysko. Florida Museum of Natural History, University of Florida. UF 155444. First county record. One adult female, heavily infested with ectoparasitic pterygosomatid mites, collected from a porch screen of a residence at 2200 h. Three other *H. mabouia* were observed at this same locality at 2000 h on 13 May 2009; they are common in sections of the Fort Pierce area. This invasive African species is currently the most widespread and rapidly spreading nonindigenous gecko in southern and central Florida (Meshaka et al. 2004. The Exotic Amphibians and Reptiles of Florida. Krieger Publ. Co., Malabar, Florida; Krysko and Daniels 2005. Caribb. J. Sci. 41:28–36), with a more recently established population in northern peninsular Florida (Krysko and Somma 2007. Herpetol. Rev. 38:352).

Submitted by **LOUIS A. SOMMA**, Department of Biology, PO Box 118525, 220 Bartram Hall, University of Florida, Gainesville, Florida 32611, USA; e-mail: somma@ufl.edu.

HEMIDACTYLUS MABOUIA (Wood Slave). TURKS AND CAICOS ISLANDS: Salt Cay: Balfour Town behind beach (21.331°N, 71.214°W; WGS 84), 1 m elev. 04 August 2008. R. Graham Reynolds and Matthew L. Niemiller. APSU 18945 (photograph). Middle Caicos: Bambarra Town, Middle Caicos Conservation Centre (21.813°N, 71.724°W; WGS84), 20 m elev.). 10 August 2008. R. Graham Reynolds and Matthew L. Niemiller. APSU 18947 (photograph). Providenciales: west end of island (21.810°N, 72.297°W; WGS84), 15 m elev. 16 July 2008. R. Graham Reynolds. APSU 18946 (photograph). All verified by Bryan Naqqi Manco. New island records (Schwartz and Henderson 1991. Amphibians and Reptiles of the West Indies: Descriptions, Distributions, and Natural History. Univ. Florida Press. 720 pp.). This exotic species is well established on the above islands, as juveniles were observed on walls of lighted buildings and nests were found under rocks or boards.

Submitted by **R. GRAHAM REYNOLDS** (e-mail: rgraham@utk.edu) and **MATTHEW L. NIEMILLER (**e-mail: mniemill@utk.edu), Department of Ecology and Evolutionary Biology, University of Tennessee, Knoxville, Tennessee 37996, USA.

HEMIDACTYLUS TURCICUS (Mediterranean Gecko). MÉXICO: CHIHUAHUA: Municipality of Juárez: Instituto de Ciencias Biomédicas de la Universidad Autónoma de Ciudad Juárez (31.747353ºN, 106.442831ºW; WGS84), 1113 m elev. 08 August 2001. Ana Gatica-Colima. Verified by Héctor Gadsden. Sección Herpetológica, Colección Científica de Vertebrados, Universidad Autónoma de Ciudad Juárez (UACJ 310–312).

First record for the municipality. The only other record for Chihuahua is at La Perla, Camargo (Lemos et al. 2007. Anfibios y Reptiles del Estado de Chihuahua, México. UNAM-CONABIO, Tlanepantla, México, México. xiii + 613 pp.), 423 km SE of Ciudad Juárez. This species is well established on walls of buildings located on the UACJ campus in Ciudad Juárez and has been reported from directly across the Río Grande in El Paso, Texas (Price 1980. Herpetol. Rev. 11:39).

Submitted by **ANA GATICA-COLIMA** (e-mail: agatica@uacj.mx), **ALEJANDRA AGUIRRE-TERRONES**, and **CÉSAR MUÑOZ-RIVAS**, Programa de Biología, Laboratorio de Ecología y Biodiversidad Animal, Universidad Autónoma de Ciudad Juárez, Estocolmo y Anillo Envolvente y PRONAF, Juárez, Chihuahua, México, CP 32310.

HEMIDACTYLUS TURCICUS (Mediterranean Gecko). USA: ALABAMA: Jefferson Co.: Homewood. 06 November 2008. Kristin A. Bakkegard. Verified by Craig Guyer. AUM 34876. Captured by hand at Mamie Mell Smith Hall on Samford University campus (33.4666ºN, 86.7935ºW; datum WGS84). Juvenile, suggesting breeding population. Six adults seen outside Mamie Mell Smith Hall on 24 June 2009 (R. Donaldson, pers comm.). New county record (Mount 1975. Amphibians and Reptiles of Alabama. Auburn University Agricultural Experiment Station, Auburn, Alabama, 347 pp.). Search of 55 museum databases (HerpNET, http://www.herpnet.org/ accessed 06 July 09) show no voucher specimens for Jefferson Co., despite range maps indicating the potential presence of this species in Jefferson Co. (Conant and Collins 1998. A Field Guide to Reptiles and Amphibians of Eastern and Central North America, 3rd ed. expanded, Houghton Mifflin, Boston, Massachusetts. 616 pp.). Moves the known range of this species 96 miles N of nearest known record in Alabama (AUM 35803, 35808, 36034–36057, Lee Co.).

Submitted by **KRISTIN A. BAKKEGARD**, Department of Biological and Environmental Sciences, Samford University, Birmingham, Alabama 35229, USA; e-mail: kbakkega@samford.edu.

HEMIDACTYLUS TURCICUS (Mediterranean Gecko). USA: ALABAMA: MONTGOMERY CO.: Captured at private residence (2611 Wildwood Drive) within Montgomery city limits (32.342544°N, 86.266818°W; WGS 84). 12 May 2009. C. and A. Kohn. Verified by Craig Guyer. AHAP-D 205. New county record (Mount 1975. Amphibians and Reptiles of Alabama. Auburn University Agricultural Experiment Station, Auburn Printing Co., Auburn, Alabama. 347 pp.).

Submitted by **SEAN P. GRAHAM**, Auburn University Department of Biological Sciences, 331 Funchess Hall, Auburn University, Alabama 36849, USA (e-mail: grahasp@auburn.edu); **CHARLES KOHN,** and **ALEX KOHN,** 2611 Wildwood Drive Montgomery Alabama, USA.

HEMIDACTYLUS TURCICUS (Mediterranean Gecko). USA: GEORGIA: SEMINOLE CO.: Brick wall of northwest corridor Charterhouse Inn, Bainbridge, along US Hwy 27 (30.88955°N, 84.565433°W; WGS84/NAD83). 31 July 2009. R. Birkhead. Verified by Craig Guyer. AUM 34917. New county record. *H. turcicus* has been documented to the north in Baker County (Jensen et al. 2008. Amphibians and Reptiles of Georgia. University of Georgia Press, Athens, Georgia. 575 pp.), but no records exist from Florida counties immediately to the south (Gadsden or Leon counties.; Townsend and Krysko 2003. Florida Sci. 66:204–208). This hotel has been frequented by local and regional herpetologists (including J. Jensen) during annual *Macrochelys* sampling trips in nearby Spring Creek for the last ten+ years, yet this is the first *H. turcicus* specimen collected, suggesting that at least this building has been recently colonized by this species within that time. The sudden appearance of disjunct populations corresponds to the stratified distribution pattern for this species predicted along trucking routes by Townsend and Krysko (*op. cit.*) and Meshaka et al. (2006. Herpetol. Cons. Biol. 1[1]:45–50). Thanks to S. Graham for reviewing this note.

Submitted by **ROGER D. BIRKHEAD**, Alabama Science In Motion, Auburn University, Alabama 36849-5414, USA; e-mail: birkhrd@auburn.edu

HEMIDACTYLUS TURCICUS (Mediterranean Gecko). USA: TEXAS: BLANCO CO.: State Highway 281, 2.99 km N of County Road 32 (30.094278ºN, 98.423167ºW; NAD27). 25 February 2008. Romey Swanson, Vincent Farallo, Jeff Troy, and Glen Hood. Verified by Toby Hibbitts, Texas Cooperative Wildlife Collection (TCWC 93008). Several individuals were seen under lights and one sub-adult was captured by hand. This individual represents the first recorded occurrence of this species in Blanco County (Dixon 2000. Amphibians and Reptiles of Texas: with Keys, Taxonomic Synopses, Bibliography, and Distribution Maps. Texas A&M University Press, College Station. 421 pp.).

Submitted by **ROMEY L. SWANSON (**e-mail: rs56761@txstate.edu), **VINCENT R. FARALLO**, **JEFF R. TROY**, **GLEN R. HOOD**, and **MICHAEL R. J. FORSTNER,** Department of Biology, Texas State University, San Marcos, Texas 78666, USA.

LEPIDODACTYLUS LUGUBRIS (Mourning Gecko). COSTA RICA: LIMÓN: Cocles, Talamanca: Gandoca-Manzanillo Wildlife Refuge (09.63818°N, 82.70496°W; WGS84), 3 m elev. 27 June 2008. Charles R. Knapp. UCR 20511. Punta Uva, Talamanca: Gandoca-Manzanillo Wildlife Refuge (09.643806°N, 82.686639°W; WGS84), 1 m elev. 23 July 2008. Juan G. Abarca and Priscilla Alvarado. UCR 20512. Both verified by Gerardo Chaves. First records for the Atlantic versant of Costa Rica, but its occurrence there was expected (Savage 2002. The Amphibians and Reptiles of Costa Rica. Univ. of Chicago Press, Chicago, Illinois. 934 pp.). The gecko in Cocles was encountered in an open-aired building at the Iguana Verde Foundation. The one at Punta Uva was found on the beach under a coconut husk.

Submitted by **JUAN G. PLESTIODON FASCIATUS (Five-lined skink). USA: GEORGIA: MADISON CO.: Eugene Odum Spring Hollow property, 0.5 km NE of intersection of Hudson River Church Rd. and Wesley Chapel Rd. (34.199431°N, 83.303010°W; WGS 84). 02 May 2009. James Moree and Charles Stoudenmire. Verified by Kenneth L. Krysko. FLMNH 155680. New county record (Jensen et al. 2008. Amphibians and Reptiles of Georgia. University of Georgia Press, Athens. 575 pp.). This record is ca. 25.7 km NE of a 1952 record from Athens-Clarke County, Georgia (GMNH 28).

Submitted by **ANDREW M. DURSO**, University of Georgia, Odum School of Ecology, Athens, Georgia 30602, USA (e-mail: amdurso@gmail.com); **JAMES MOREE**, University of Georgia, Odum School of Ecology, Athens, Georgia 30602, USA (e-mail: jmoree@uga.edu); and **CHARLES STOUDENMIRE**, University of Georgia, Franklin College of Arts & Sciences, Athens, Georgia 30602, USA (e-mail: stoudey@uga.edu).

PLESTIODON MULTIVIRGATUS (Many-lined Skink). USA: NEBRASKA: VALLEY CO., 16.1 km N, 8 km E Ord (41.74043°N, 98.81868°W; NAD 83). 02 August 2008. Greg D. Wright and Keith Geluso. Verified by Travis Taggart. Sternberg Museum of Natural History, Hays, Kansas (MHP 14309, photographic voucher). First county record. Fills in gap along southern boundary of distribution in Nebraska (Lynch 1985. Trans. Nebraska Acad. Sci. 13:33–57). Known from adjacent Greeley County to the east (Lynch 1985. *op. cit.*). Individual was stripeless and had a tail partially regenerated. Stripeless individuals previously were known from Arthur, Brown, and Keith Counties (Lynch 1985, *op. cit.*).

Submitted by **GREG D. WRIGHT** and **KEITH GELUSO** Department of Biology, University of Nebraska—Kearney, Kearney, Nebraska 68849, USA; e-mail: gelusok1@unk.edu.

PODARCIS MURALIS (European Wall Lizard). USA: KENTUCKY: BOONE CO.: near confluence of Woolper Creek and the Ohio River (39.0198ºN, 84.8595ºW; WGS 84). October 2008. Scott Fennell. Verified by Jeffrey M. Goessling. Cincinnati Museum Center Herpetology Photographic Collection (CMC HP 5078 [digital file and print]). New county record (Ferner 2004. J. Kentucky Acad. Sci. 65[1]:1–4). An adult was found on rocks near shore. Anecdotal reports of others seen in area.

Submitted by **SCOTT FENNELL**, Center for Applied Ecol-

ogy, Northern Kentucky University, Highland Heights, Kentucky 41076, USA; and **JOHN W. FERNER**, Department of Biology, Thomas More College, Crestview Hills, Kentucky 41017, USA (e-mail: john.ferner@thomasmore.edu).

SCINCELLA GEMMINGERI (Forest Ground Skink). MÉXICO: CHIAPAS: Municipality of Villa Flores: 2.3 km N of Tierra y Libertad (16.2440ºN, 93.2678ºW; WGS84), 1095 m elev. 09 September 2006. Itzel Durán Fuentes and Edmundo Perez Ramos. Museo de Zoología, Facultad de Ciencias, UNAM (MZFC 22725–27). 3.3 km SE Tierra y Libertad (16.2276ºN, 93.30972ºW; WGS84), 1294 m elev. 08 September 2006. Uri Omar García Vázquez and Itzel Durán Fuentes. MZFC 22728–29. All verified by Luis Canseco Márquez. First records for Villa Flores and the Sierra Madre de Chiapas (in Chiapas), second series from the state, and extends the known range in Chiapas ca. 87 km (airline) SW from the Tuxtla Gutierrez-Cañon del Sumidero road, north of Tuxtla Gutierrez on the southern edge of the Northern Highlands region of Chiapas (Luna-Reyes et al. 2007. Herpetol. Rev. 30:353). The closest previously known locality is about 55 km NW at Rodulfo Figueroa, Oaxaca (MZFC 15558), which is also located in the Sierra Madre de Chiapas. All specimens were active during the day in pine forest.

Submitted by **URI OMAR GARCÍA-VÁZQUEZ** (e-mail: urigarcia@gmail.com), **EDMUNDO PÉREZ-RAMOS,** and **ITZEL DURÁN-FUENTES,** Laboratorio de Herpetología, Museo de Zoología, Facultad de Ciencias, UNAM, A.P. 70-399, México D.F. 04510, México.

SCINCUS MITRANUS (NCN). IRAN: KHUZESTAN PROVINCE: Kupal dunes, sand dunes 53 km E Ahvaz via Ahvaz-Haftgel Road (31.2731667ºN, 49.2365ºE; no datum available; 75 m elev.). 10 May 2001. T. J. Papenfuss. University of California, Berkeley, Museum of Vertebrate Zoology, MVZ 234488–91, 234535–8. First record for Iran. Habitat described by Anderson (1999. The Lizards of Iran. SSAR Contrib. Herpetol., Vol. 15. vii + 442 pp. Ithaca, New York). Species known from similar habitat in Saudi Arabia, UAE, and Oman. Occurrence at this locality is somewhat surprising, as *S. scincus conirostris* occurs in similar habitat 90 km to southeast. However, the two species are sympatric, if not syntopic, on the Arabian Peninsula. Specimens in agreement with those collected in UAE and with 110 specimens in the California Academy of Sciences, collected by John Gasperetti and others elsewhere on the Arabian Peninsula.

SQUAMATA – SNAKES

AGKISTRODON CONTORTRIX (Copperhead). USA: TENNESSEE: Cannon Co.: Burt Burgen Road at Cove Hill Road intersection (36.7311ºN, 86.1219ºW; NAD83). 24 June 2007. Brian T. Miller. Verified by M. L. Niemiller. Adult found dead on road. Deposited in the Herpetology Collection at Middle Tennessee State University (MTSU 181S). First record for county, which also decreases size of conspicuous gap in records reported for central Tennessee (Scott and Redmond 2008. Atlas of Reptiles in Tennessee. Center for Field Biology, Austin Peay State University, Clarksville, Tennessee. Available from http://www.apsu.edu/reptatlas; accessed 04 June 2009).

Submitted by **JOSHUA A. MILLER**, Sinks Miller Road, Bradyville, Tennessee 37026, USA; **JACOB H. MILLER**, Sinks Miller Road, Bradyville, Tennessee 37026, USA; and **JOYCE L. MILLER**, MIMIC, Middle Tennessee State University, Murfreesboro, Tennessee 37132, USA (e-mail: jlmiller@mtsu.edu).

AGKISTRODON PISCIVORUS (Cottonmouth). USA: TENNESSEE: Coffee Co.: Duck River (35.5ºN, 86.0ºW; datum WGS 84). 25 July 2008. Rob Colvin. Verified by Jack Sites. Brigham Young University, BYU 5379. Gloyd and Conant (1990. Snakes of the *Agkistrodon* Complex: A Monographic Review. Society for the Study of Amphibians and Reptiles, Oxford, Ohio. 614 pp.) and the Tennessee Reptile Atlas (http://www.apsu.edu/reptatlas/frames_file.htm, accessed 27 May 2009) report the occurrence of an isolated, potentially introduced population of *Agkistrodon piscivorus* in Coffee County but provide no documentation. We were unable to locate any museum specimens of *A. piscivorus* from Coffee County (http://www.herpnet.org, accessed 30 May 2009) and here report a new county record, a male, with a snout to vent length of 79.7 cm and mass of 600 g.

Collection was made under the authority of Tennessee Wildlife Resources Agency Scientific Collection Permit #3486. Tissue is available by request from the authors.

Submitted by **BRYAN HAMILTON,** 100 Great Basin National Park, Baker Nevada 89311, USA (e-mail: bryan_hamilton@nps.gov); and **ROBERT COLVIN,** Tennessee Wildlife Resources Agency, Region I, 200 Lowell Thomas Dr, Jackson, Tennessee 38301, USA.

AGKISTRODON PISCIVORUS LEUCOSTOMA (Western Cottonmouth). USA: ARKANSAS: Cleburne Co.: Near Brewer Road 3.37 miles NW of AR 225 (35.67192ºN, 92.15800ºW; WGS84; elev. 234 m). 13 Sep 2008. Thomas J. Belford. University of Kansas Natural History Museum (KUDA 6357). Verified by William E. Duellman. Single specimen was found thermoregulating near the opening of a den site. First county record; extends range 10.11 km from nearest known record in Van Buren County, Arkansas (Trauth et al. 2004. The Amphibians and Reptiles of Arkansas. Univ. of Arkansas Press, Fayetteville. 421 pp.).

Submitted by **THOMAS J. BELFORD**, 701 West Academy Avenue, Searcy, Arkansas 72143, USA; e-mail: thomasbelfordiniraq@yahoo.com.

AGKISTRODON PISCIVORUS PISCIVORUS (Eastern Cottonmouth). USA: SOUTH CAROLINA: Edgefield Co.: 15.5 km N of Edgefield, where SC Highway 25 crosses Turkey Creek. 100 m E of the SC Highway 25 bridge. 20 August 2006. Photographic record South Carolina State Museum 2006.39.1a, 1b (photographs by K. Knight). Verified by J. Camper. New county record (Gloyd

and Conant 1990. Snakes of the *Agkistrodon* Complex: A Monographic Review. SSAR Contrib. Herpetol., No. 6). Inland-most record for South Carolina, first record for the central Piedmont of the state, first record for Edgefield Co. A second, larger specimen was observed ca. 200 m downstream of the above locality on 27 August 2006.

Submitted by **JAMES L. KNIGHT**, South Carolina State Museum, 301 Gervais St., Columbia, South Carolina 29202, USA; e-mail: jim.knight@scmuseum.org.

CEMOPHORA COCCINEA (Scarletsnake). USA: GEORGIA: Bartow Co.: White, Macedonia Road, 1.0 mi SE Macedonia Camp Road (34.16937°N, 84.66865°W, WGS84; elev. 304 m). 07 July 2009. Justin T. Oguni. Verified by Kenneth L. Krysko. Florida Museum of Natural History (photographic voucher UF 155510). New county record (Jensen et al. 2008. Amphibians and Reptiles of Georgia. University of Georgia Press. 575 pp.). Found AOR at 2225 h surrounded by mixed pine-hardwood forest.

Submitted by **JUSTIN T. OGUNI**, College of Veterinary Medicine, University of Georgia, Athens, Georgia 30602, USA; e-mail: goonie16@gmail.com

CEMOPHORA COCCINEA COPEI (Northern Scarletsnake). USA: ARKANSAS: Cleburne Co.: Specimen was found near Pickens Mountain road 1.1 miles N of AR 310 (35.36305º N, 091 52.220ºW; WGS84; elev. 95 m). 05 Jun 2009. Thomas J. Belford and Madison K. Price. The University of Kansas Natural History Museum (KUDA 6829). Verified by William E. Duellman. Single specimen was found beneath a rock in cedar glade habitat. First county record; extends range 15.41 km from nearest known record in White County, Arkansas (Trauth et al. 2004. The Amphibians and Reptiles of Arkansas. Univ. Of Arkansas Press, Fayetteville. 421 pp.).

Submitted by **THOMAS J. BELFORD**, 701 West Academy Avenue, Searcy, Arkansas 72143, USA (e-mail: thomasbelford iniraq@yahoo.com); and **MADISON K. PRICE** 244 Pickens Mountain Road, Searcy, Arkansas 72143, USA.

CLONOPHIS KIRTLANDII (Kirtland's Snake). USA: ILLINOIS: DeKalb Co.: 2.4 km W of Sandwich. 08 October 1961. Juvenile specimen collected by Harlan D. Walley and deposited in the Michigan State University Museum. Verified by James Harding. MSUM HE.14207. This previously overlooked specimen represents a new county record (Phillips et al. 1999. Field Guide to Amphibians and Reptiles of Illinois. Illinios Natural History Survey. 300 pp.). Based on the timing and format of written records, this specimen probably came to the Michigan State University Museum via Dr. Marvin "Max" Hensley who taught herpetology at MSU and maintained a collection in the Department of Zoology. Following his retirement in 1986, herpetological specimens collected in the 1950s, 1960s, and early 1970s were transferred to the MSU Museum (Laura Abraczinska, MSU Museum, pers. comm.). In a conversation with RBK in spring 2008, Harlan Walley (since deceased) recalled collecting this specimen but was unsure how it ended up at MSU.

Submitted by **RICHARD B. KING**, Department of Biological Sciences, Northern Illinois University, DeKalb, Illinois 60115, USA.

COLUBER (= MASTICOPHIS) FLAGELLUM FLAGELLUM (Eastern Coachwhip). USA: ARKANSAS: Searcy Co.: vic. Mull, ~3 km S of jct AR 14 and Ramblewood Trail (36.052048°N, 92.594601°W; WGS 84). 11 June 2009. M. B. Connior. Verified by S. E. Trauth. Arkansas State University Museum of Zoology Herpetology Collection (ASUMZ 31369).. This female is a new county record partially filling a distributional hiatus among previous records in Marion, Baxter, and Stone counties in northern Arkansas (Trauth et al. 2004. The Amphibians and Reptiles of Arkansas. University of Arkansas Press, Fayetteville. 421 pp.).

Submitted by **MATTHEW B. CONNIOR**, Department of Biological Sciences, Arkansas State University, P.O. Box 599, State University, Arkansas 72467, USA; e-mail: matthew.connior@smail.astate.edu.

DIADOPHIS PUNCTATUS (Ring-necked Snake). USA: GEORGIA: Madison Co.: Eugene Odum Spring Hollow property, 0.5 km NE of intersection of Hudson River Church Rd. and Wesley Chapel Rd. (34.199431°N, 83.303010°W; WGS 84). 02 May 2009. Collected by JM and CS. Verified by Kenneth L. Krysko. FLMNH 155679. New county record (Jensen et al. 2008. Amphibians and Reptiles of Georgia. University of Georgia Press, Athens. 575 pp.). An adult *D. punctatus* was hand captured beneath a log at 1115 h. This record is ca. 29.5 km NE of a 1950 record from Athens-Clarke County, Georgia (GMNH 6870).

Submitted by **ANDREW M. DURSO** (e-mail: amdurso@gmail.com) and **JAMES MOREE**, University of Georgia, Odum School of Ecology, Athens, Georgia 30602, USA (e-mail: jmoree@uga.edu); and **CHARLES STOUDENMIRE**, University of Georgia, Franklin College of Arts & Sciences, Athens, Georgia 30602, USA (e-mail: stoudey@uga.edu).

DRYMARCHON CAUDOMACULATUS (Falcon Indigo Snake). COLOMBIA: DEPARTAMENTO DE GUAJIRA: Municipio de Uribia, Corregimiento de Nazareth, vereda Yorijaru 12.181°N 71.28°W (datum MAGNA-SIRGAS), 107 m elev. M. Fernandez. 12 July 2008. Colección de Herpetología, Museo de Historia Natural ANDES, Universidad de los Andes, Bogotá, Colombia (ANDES-R 169). Verified by W. Wüster. Previously known from Falcon and Zulia states, Venezuela (Wüster et al. 2001. Herpetol. J. 11:157–165; Infante Rivero et al. 2005. Herpetol. Rev. 36:203). First country record extends range ca. 200 airline km NW from Falcon and 280 airline km NW from Zulia state, Venezuela.

Submitted by **JUAN SALVADOR MENDOZA** and **MATEO FERNANDEZ LUCERO**, Museo de Historia Natural, Universidad de los Andes, Colección de Herpetología, Bogotá, Colombia.

EPICRATES MONENSIS GRANTI (Virgin Islands Treeboa). BRITISH VIRGIN ISLANDS: Great Camanoe Island: near boat dock on a stone wall in a drainage culvert (18.46293°N, 64.53426°W; NAD83), 50 m elev. 20 October 2008. Brittany S. Barker. Verified by J. Lazell. MPM-P 740 (photograph). First documented record for island. Lazell (1983. *In* Rhodin and Miyata [eds.], Advances in Herpetology and Evolutionary Biology: Essays in Honor of Ernest E. Williams, pp. 99–117. Mus. Comp. Zool., Harvard Univ., Cambridge, Massachusetts) reported a sight record, but without a voucher. The snake was found at night perched on the wall in an area surrounded by subtropical dry forest.

Financial support for this work was provided by The Conservation Agency through a grant from the Falconwood Foundation.

Submitted by **BRITTANY S. BARKER**, Department of Biology, University of New Mexico, Albuquerque, New Mexico 87131, USA (e-mail: barkerbr@unm.edu); **ROBERT W. HENDERSON**, Milwaukee Public Museum, Milwaukee, Wisconsin 53233, USA (e-mail: henderson@mpm.edu); and **ROBERT POWELL**, Avila University, Kansas City, Missouri 64145, USA (e-mail: Robert.Powell@avila.edu).

FARANCIA ABACURA REINWARDTII (Western Mudsnake). USA: ARKANSAS: CALHOUN CO.: ~3 km N of Ouachita River on US 167 (33.3724°N, 925101°W; WGS 84). 27 September 2009. M. B. Connior. Verified by S. E. Trauth. Arkansas State University Museum of Zoology Herpetology Collection (photo voucher ASUMZ 31375). DOR. This adult is a new county record filling a distributional hiatus among previous records in Dallas, Bradley, Ouachita, and Union counties in southern Arkansas (Trauth et al. 2004. The Amphibians and Reptiles of Arkansas. University of Arkansas Press, Fayetteville. 421 pp.).

Submitted by **MATTHEW B. CONNIOR,** Health and Natural Sciences, South Arkansas Community College, PO Box 7010, 300 South West Avenue, El Dorado, Arkansas 71731, USA; e-mail: mconnior@southark.edu.

HETERODON PLATIRHINOS (Eastern Hog-nosed Snake). USA: WISCONSIN: BUFFALO CO.: North of Fountain City (44.177489°N, 91.758078°W; datum WGS84). 13 June 2009. Verified by Erik Wild. Illinois Natural History Survey INHS 2009o (photograph). New county record. Fills gap in known range of species in Wisconsin (Casper 1996. Geographic Distributions of the Amphibians and Reptiles of Wisconsin. Milwaukee Public Museum, 87 pp.). Discovered in a residential development surrounded by disturbed sand prairie/fallow grassland at the base of bluff habitat.

Submitted by **JASON BECKER**, W522 State Road 35, Fountain City, Wisconsin, USA; **PATRICK THORSELL** and **LISA THORSELL**, S2887 Willow Lane, Fountain City, Wisconsin, USA; and **JOSHUA M. KAPFER**, Natural Resources Consulting, Inc., 209 Commerce Parkway, PO Box 128, Cottage Grove, Wisconsin 53527, USA.

LAMPROPELTIS GETULA (Common Kingsnake). USA: GEORGIA: MADISON CO.: A live adult found at 1400 h on a snowdrift at a private residence (34.075994°N, 83.363706°W; WGS 84). 03 March 2009. Shelby Jarrett and Carla Jarrett. Verified by Kenneth L. Krysko. FLMNH 155682. A DOR adult *L. getula* was found on GA-106, 0.17 km N of intersection with Ben Crawford Rd (34.092558°N, 83.312641°W; WGS 84). 02 May 2009. Andrew M. Durso. Verified by M. Elizabeth McGhee. GMNH 50117. New county records (Jensen et al. 2008. Amphibians and Reptiles of Georgia. University of Georgia Press, Athens. 575 pp.). These records are ca. 18.1 km NW and 15.3 km N of a 1952 record from Athens-Clarke County, Georgia (GMNH 116), respectively.

Submitted by **ANDREW M. DURSO**, University of Georgia, Odum School of Ecology, Athens, Georgia 30602, USA (e-mail: amdurso@gmail.com); **SHELBY JARRETT, CARLA JARRETT (**e-mail: cjarrett@uga.edu**),** and **JUSTIN T. OGUNI** (e-mail: goonie16@gmail.com), University of Georgia, College of Veterinary Medicine, Athens, Georgia 30602, USA.

LEPTOPHIS DEPRESSIROSTRIS (NCN). HONDURAS: GRACIAS A DIOS: Raudal Kiplatara, nuclear zone of Río Platano Biosphere Reserve (15.6150°N, 84.9608ºW; WGS 84), 270 m elev. 07 August 2003. Jorge A. Ferrari. Forschungsinstitut Senckenberg (SMF 86015). Pomokir, nuclear zone of Río Platano Biosphere Reserve (15.4885°N, 84.9535W; WGS 84), 200 m elev. 23 January 2004. Jorge A. Ferrari. SMF 86016. Both verified by Javier Sunyer. First records for Honduras (Köhler 2008. Reptiles of Central America. 2nd ed. Herpeton Verlag E. Köhler, Offenbach, Germany. 400 pp.); McCranie et al. 2006. The Amphibians and Reptiles of the Honduran Mosquitia. Krieger Publ. Co., Malabar, Florida. 291 pp.). The nearest record is about 160 km SSW in Reserva Biosfera Bosawas, Jinotega, Nicaragua (Köhler 2001. Anfibios y Reptiles de Nicaragua. Herpeton Verlag E. Köhler, Offenbach, Germany. 208 pp.).

Submitted by **GUNTHER KÖHLER,** Forschungsinstitut und Naturmuseum Senckenberg, Senckenberganlage 25, 60325 Frankfurt a.M., Germany (e-mail: gkoehler@senckenberg.de); and **JORGE A. FERRARI**, Organización de Rescate y Protección de Reptiles y Anfibios de Honduras, Apdo. Postal 30.724 Tocontin, Tegucigalpa, Honduras (e-mail: herpetoking@yahoo.com).

LEPTOPHIS DIPLOTROPIS (Pacific Coast Parrot Snake). MÉXICO: GUANAJUATO: Municipality of Yuriria: Cerro La Angostura (20.28083ºN, 101.10805ºW; WGS84), 1824 m elev. 22 May 2006. Marina Sánchez Luna and Adriana J. González Hernández. Verified by Edmundo Pérez Ramos. Colección Nacional de Anfibios y Reptiles, Instituto de Biología, Universidad Nacional Autónoma de México, México (IBH 21959). First state record, and extends the range of the species ca. 146 km NE from closest known locality at Nuevo Urecho, Michoacán (González and Garza 2006. *In* Ramírez-Bautista et al. [eds.], Inventarios Herpetofaunísticos de México: Avances en el Conocimiento de su Biodiversidad, pp. 140–151. Publ. Soc. Herpetol. Mexicana No. 3, México, D.F.). The snake was found in secondary vegetation next to a remnant patch of tropical deciduous forest. Project was supported by Fondos Mixtos de Conacyt-Concyteg, grant number 04-07-A-051.

Submitted by **MARINA SÁNCHEZ-LUNA**, Facultad de Agrobiología, Universidad Autónoma de Tlaxcala, Carretera Autopista Tlaxcala-San Martin, San Felipe Ixtacuixtla Tlaxcala, México; and **ADRIANA J. GONZÁLEZ-HERNÁNDEZ, ELISA CABRERA-GUZMÁN**, and **VÍCTOR H. REYNOSO (**e-mail: vreynoso@ibiologia.unam.mx), Colección Nacional de Anfibios y Reptiles, Instituto de Biología, Departamento de Zoología, Universidad Nacional Autónoma de México, Circuito Exterior Ciudad Universitaria, México D.F., C.P. 04510.

MICRUROIDES EURYXANTHUS (Sonoran Coral Snake). MÉXICO: CHIHUAHUA: Municipality of Urique: 7.2 km E of El Divisadero, near Río Urique (27.496389°N, 107.796°W; WGS84). 28 July 2008. Javier Guardado. Verified by Pablo Lavín. Seccion de Herpetología, Coleccion Científica de Vertebrados, Univesidad Autónoma de Ciudad Juárez, Colección digital (CCV-UACJ 12-29 08). First record for the municipality, extending the range 52.38 km N of Batopilas, Batopilas (Lemos Espinal and Smith 2007. Anfibios

y Reptiles del Estado de Chihuahua, México. UNAM-CONABIO. xii + 613 pp.). The snake was found at 1300 h laying on a rock near a small creek surrounded by gallery forest.

Submitted by **JAVIER GUARDADO** and **ANA GATICA-COLIMA (**e-mail: agatica@uacj.mx), Programa de Biología, Laboratorio de Ecología y Biodiversidad Animal, Universidad Autónoma de Ciudad Juárez, Estocolmo y Anillo Envolvente y PRONAF, CP. 32310, Juárez, Chihuahua, México.

NERODIA TAXISPILOTA (Brown Watersnake). USA: SOUTH CAROLINA: York Co.: DOR adult on West Oak Road ca. 1 km W. of Pennington Rd., about 1 km from Big Dutchman Creek, the nearest water source. 19 June 2001. Steven Fields. Verified by Jeff Camper. Cultural and Heritage Museum of York County 2009.015.001, photographic record. Additional sight records on file at the Cultural and Heritage Museum of York County. First record for York County (Gibbons and Dorcas 2004. North American Water Snakes: A Natural History. Univ. Oklahoma Press, Norman. 438 pp.).

Submitted by **STEVEN E. FIELDS**, Cultural and Heritage Museum of York County, Rock Hill, South Carolina 29732, USA; and **JAMES L. KNIGHT**, South Carolina State Museum, 301 Gervais Street, Columbia, South Carolina 29202, USA (e-mail: jim.knight@scmuseum.org).

NINIA ESPINALI (Espinal's Coffee Snake). HONDURAS: COMAYAGUA: Parque Nacional Cerro Azul Meámbar, from the western side of Cerro Azul on a steep slope ca. 200 m above the Río de Varsovia (14.826389°N, 87.883333°W; WGS84), 1660 m elev. 09 July 2008. Ileana R. Luque-M. and Josiah H. Townsend. Verified by Larry David Wilson. UF 155102. First record for the Department of Comayagua and easternmost locality for the species, extending the range ca. 85 km SSE of records in Parque Nacional Cusuco, Cortés, and ca. 75 km N of localities in the vicinity of Guajiquiro, La Paz (McCranie and Wilson 1995. J. Herpetol. 29:224–232). The snake was found crawling at night on a steep slope in an exposed root mass of a tree in lower montane wet forest.

Submitted by **ILEANA R. LUQUE-MONTES**, Instituto Regional de Biodiversidad (IRBio), Centro Zamorano de Biodiversidad, Escuela Agrícola Panamericana Zamorano, Honduras (e-mail: ileanaluquem@gmail.com); and **JOSIAH H. TOWNSEND**, School of Natural Resources and Environment, and Florida Museum of Natural History, University of Florida, Gainesville, Florida 32611-7800, USA (e-mail: jtwnsnd@ufl.edu).

OPHEODRYS AESTIVUS (Rough Greensnake). USA: GEORGIA: Oglethorpe Co.: Carlton, New Hope Vesta Road, 1.0 mi SE McCannon Road (33.93019°N, 82.90739°W, WGS84; elev. 144 m). 28 April 2009. Justin T. Oguni. Florida Museum of Natural History (photographic voucher UF 155271). New county record (Jensen et al. 2008. Amphibians and Reptiles of Georgia. University of Georgia Press, Athens. 575 pp.). Found AOR at 1610 h in undeveloped forest and temporary wetlands with small streams. Wilkes Co.: Tignall, CR 184, 4.8 km E Newtown Road (33.89546°N, 82.79621°W, WGS84; elev. 160 m). 13 May 2009. Justin T. Oguni. UF 155334, photographic voucher. New county record (Jensen, *op. cit*.) Found DOR at 1518 h in undeveloped forest. Both verified by Kenneth L. Krysko.

Submitted by **JUSTIN T. OGUNI**, College of Veterinary Medicine, University of Georgia, Athens, Georgia 30602, USA; e-mail: goonie16@gmail.com.

OPHEODRYS VERNALIS (Smooth Greensnake). USA: NEBRASKA: Webster Co.: Nebraska Highway 4, 3.5 km S, 5.25 km E Bladen (40.29232°N, 98.65855°W, NAD 83). 23 July 2008. Keith Geluso and Greg D. Wright. Verified by Travis Taggart. Sternberg Museum of Natural History, Hays, Kansas (MHP 14310, photographic voucher). First county record. Southernmost record in Nebraska, where it is documented from only four counties (Lynch 1985. Trans. Nebraska Acad. Sci. 13:33–57).

Submitted by **KEITH GELUSO** (e-mail: gelusok1@unk.edu), and **GREG D. WRIGHT**, Department of Biology, University of Nebraska—Kearney, Kearney, Nebraska 68849, USA.

OPHEODRYS VERNALIS (Smooth Greensnake). USA: OHIO: Greene Co.: Bath Township. Prairie Road (39.80587°N, 84.07247°W; WGS 84). 20 May 2009. William J. Letsche and Jeffrey G. Davis. Verified by John W. Ferner. Cincinnati Museum Center (CMC 11600). New county record and first record for this species in southwest Ohio since 1961 (Wynn and Moody 2006. Ohio Turtle, Lizard, and Snake Atlas. Ohio Biol. Surv. Misc. Contrib. No. 10, Columbus).

Submitted by **JEFFREY G. DAVIS**, Cincinnati Museum Center, Fredrick and Amye Geier Research and Collections Center, 1301 Western Avenue, Cincinnati, Ohio 45203-1130, USA (e-mail: anura@fuse.net); and **WILLIAM J. STORERIA DEKAYI (DeKay's Brownsnake). USA: OHIO: Gallia Co.: Greenfield Township. C, H, and D Road (38.8058°N, 82.5397°W; WGS 84). 04 April 2008. Jeffrey G. Davis and Paul J. Krusling. Verified by John W. Ferner. Cincinnati Museum Center (CMC 11022). New county record (Wynn and Moody 2006. Ohio Turtle, Lizard, and Snake Atlas. Ohio Biol. Surv. Misc. Contrib. No. 10, Columbus).

Submitted by **JEFFREY G. DAVIS (**e-mail: anura@fuse.net) and **PAUL J. KRUSLING** (e-mail: krusling@fuse.net), Cincinnati Museum Center – Fredrick and Amye Geier Research and Collections Center, 1301 Western Ave., Cincinnati, Ohio 45203-1130, USA.

STORERIA OCCIPITOMACULATA (Red-bellied Snake). USA: ARKANSAS: Cross Co.: near Village Creek State Park, 6.0 mi. S US 64 (35.1620167°N, 90.7205833°W; WGS84; elev. 97 m). 10 Jun 2009. Thomas J. Belford. Verified by William E. Duellman. University of Kansas Natural History Museum (KUDA 6907–08). First county record, extending range 35 km from nearest known record in St. Francis County, Arkansas (Trauth et al. 2004, The Amphibians and Reptiles of Arkansas. Univ. of Arkansas Press, Fayetteville. 421 pp.).

Submitted by, **THOMAS J. BELFORD**, 701 W Academy Avenue, Searcy, Arkansas 72143, USA; e-mail: thomasbelfordini raq@yahoo.com.

TANTILLA YAQUIA (Yaqui Black-headed Snake). MÉXICO: SONORA: Municipality of Guaymas: SW slope of the Sierra El Aguaje, 5.75 km (airline) N of San Carlos (27.983573°N, 111.083391°W; NAD27), 60 m elev. 18 December 2008. M. Bogan and L. Findley. Verified by Charles J. Cole. UAZ 57150-PSV (photo). First municipality record, extending the range ca. 222 km (airline) NW of the vicinity of Navojoa, Sonora (McDiarmid 1977. Cat. Amer. Amphib. Rept. 198.1–2) and 242 km (airline) WSW of Maycoba, Sonora (Lemos-Espinal et al. 2004. Bull. Chicago Herpetol. Soc. 39:206–213). This important biogeographical record marks first known observation of the species from Sonoran Desertscrub (*Acacia willardiana*, *Bursera microphylla*, *Parkinsonia [=Cercidium] microphylla*, and *Stenocereus thurberi*), and represents an isolated locality that is well removed from the main distribution of *T. yaquia* in the Sierra Madre Occidental region where it occurs in oak woodland, tropical deciduous forest, and thornscrub. The snake was discovered on an open, south-facing rocky hillside located about 15 m upslope from a subtropical riparian-lined canyon consisting of *Sabal uresana* and *Ficus petiolaris*.

Submitted by **MICHAEL T. BOGAN**, Department of Zoology, Oregon State University, 3029 Cordley Hall, Corvallis, Oregon 97331, USA; **LLOYD T. FINDLEY**, Centro de Investigación en Alimentación y Desarrollo-Unidad Guaymas, Carretera al Varadero Nacionál Km. 6.6, Guaymas, Sonora, Mexico 85480; and **ERIK F. ENDERSON**, Drylands Institute, PMB 405 2509 North Campbell Avenue, Tucson, Arizona 85719, USA (e-mail: erikenderson@msn.com).

THAMNOPHIS SAURITUS (Eastern Ribbonsnake). USA: GEORGIA: Elbert Co.: Elberton, River Road, 1.0 km W SR 79 (33.99865°N, 82.65883°W, WGS84; elev. 135 m). 08 May 2009. Justin T. Oguni. Verified by Kenneth L. Krysko. Florida Museum of Natural History (photographic voucher UF 155322). New county record (Jensen et al. 2008. Amphibians and Reptiles of Georgia. University of Georgia Press, Athens. 575 pp.). Found AOR at 2043 h in undeveloped forest with interspersed wetlands and small streams.

Submitted by **JUSTIN T. OGUNI**, College of Veterinary Medicine, University of Georgia, Athens, Georgia 30602, USA; e-mail: goonie16@gmail.com.

THAMNOPHIS SAURITIS (Eastern Ribbonsnake). USA: OHIO: Tuscarawas Co.: Wayne Township. Dundee Wilmont Road NW (40.59683°N, 81.61469°W; WGS 84). 13 July 2009. Greg Lipps Jr., Jeffrey G. Davis, and Ralph A. Pfingsten. Verified by John W. Ferner. Cincinnati Museum Center (CMC 11706). New county record (Wynn and Moody 2006. Ohio Turtle, Lizard, and Snake Atlas. Ohio Biol. Surv. Misc. Contrib. No. 10, Columbus).

Submitted by **JEFFREY G. DAVIS**, Cincinnati Museum Center – Fredrick and Amye Geier Research and Collections Center, 1301 Western Avenue, Cincinnati, Ohio 45203-1130, USA (e-mail: anura@fuse.net); **GREGORY J. LIPPS JR.,** 1473 County Road 5-2, Delta, Ohio 43515, USA (e-mail: GregLipps@aol.com); and **RALPH A. PFINGSTEN**, Cleveland Museum of Natural History, 1 Wade Oval, University Circle, Cleveland, Ohio 44106, USA (e-mail: RAP@wideopenwest.com).

TROPIDOPHIS MORENOI (NCN). CUBA: CIEGO DE ÁVILA: Bolivia Municipality: Loma de Cunagua (22.099658°N, 78.450001°W; WGS84). August or September 1999. O. Martínez. Photographic collection of the Centro de Investigaciones de Ecosistemas Costeros, Cayo Coco, Ciego de Ávila (CIEC 66). Morón Municipality: Alevinaje (22.118611°N, 78.599444°W; WGS84), 16 m elev. 14 December 2000. E. Socarrás. CIEC 67. Sabana-Camagüey Archipelago: Coco Key (22.498333°N, 78.461111°W; WGS84). 05 November 1996. O. Moreno. CIEC 150. All verified by L. V. Moreno. First records for Ciego de Ávila Province, and in the case of CIEC 150, for Coco Key and the Sabana-Camagüey Archipelago, extending the range 75.6 km E from Caguanes, the only other known record at the type locality in Sancti Spiritus Province (Hedges 2002. Bull. Nat. Hist. Mus. London [Zool.] 68:83–90. Three species of *Tropidophis* were previously known from Coco Key: T. *melanurus* (Estrada 1993. Poeyana 432:1–21); *T. pardalis* (Garrido 1976. Misc. Zool. 3:3–4); and *T. semicinctus* (Martinez-Reyes et al. 2005. Poeyana 493:1–11), so with the addition of *T. morenoi*, Coco Key contains the highest number of species among Cuban keys, being only surpassed by 12 species found on the mainland (Hedges, *op. cit*.).

Flores-Villela and Pérez-Mendoza (2006) presented a compilation of literature citations addressing the herpetofauna of each of the 32 states in México, therein indicating that Tamaulipas was one of the most, if not the most, data deficient states in México. Ongoing field surveys in Tamaulipas continue to produce noteworthy records and included herein is significant distributional information on 23 species, including four new state records. The information presented is expressed in the same manner as established in Farr et al. (2007), with the addition of the museum abbreviation: University of Texas, Arlington, Digital Collection (UTADC). In addition to literature sources and our own field observations, approximately 12,000 museum records (of which about 39% have been examined by us) from the state were considered when creating the following species accounts and are specified in parentheses in the text as having been examined, or not examined, by the authors. The vegetation associations used here (and generally in Farr et al. 2007) are derived from Martin (1958), which in turn are equivalent to eight of the 12 vegetation zones in México recognized by Leopold (1950). We use the term "Chihuahuan Desert scrub" to describe the primary vegetation type found in the municipality of Tula and areas at lower elevations in the municipalities of Bustamante and Miquihuana. Locality coordinates and elevations of our original field data were determined using a GPS device, but those of museum and literature records are expressed in the manner established by Farr et al. (2007) using topographic maps; both used map datum WGS84. The standard English and scientific names follow Liner and Casas-Andreu (2008). The state of Tamaulipas is divided into 43 municipalities (equivalent to U.S. counties) and the capital of each is a city or town bearing the same name. In the following text, when referring to municipalities, they are specified as such (i.e., Municipio Tula or municipality of Tula) and the capital community is referred to only by its name (e.g., Tula).

Caudata

Pseudoeurycea cephalica (Chunky False Brook Salamander). Municipio Tula/Ocampo (near border): near Lagunas Las Hondas, 24 km SE of Tula (22.8125°N, 99.558333°W), 1206.3 m elev. 24 August 2006. William Farr. Verified by Fernando Mendoza-Quijano. UANL 6461. Southernmost record for the species in Tamaulipas, extending its range 44 km SW from the closest reported locality (Martin 1958) at Agua Linda [23.066667°N, 99.233333°W], 1800 m elev. in the Sierra de Guatemala (= El Cielo International Biosphere Reserve). Two additional individuals were observed at this locality and all were found in or under dead logs in humid oak forest. Additionally, we have observed *P. cephalica* (and *P. scandens*) at an intermediate locality near Mexican Hwy 66 in humid oak forest, 15 km E of Tula (22.930833°N, 99.586111°W, 1376.4 m elev.) in the municipality of Tula. Martin (1958) reported a hiatus in the distribution of *P. cephalica* (and *P. belli*) between populations in the cloud forest of the Sierra de Guatemala, Tamaulipas, and northern Hidalgo, a distance of *ca.* 220 km (and *P. belli* populations near Xilitla, San Luis Potosí). The locality recorded here closes this gap by 20%. Wake and Lynch (1976) inferred the distribution of the genus (*P. cephalica* and/or *P. belli* by implication) to be continuous without supporting localities. Approximately 35 km to the south across the state line in San Luis Potosí, there is an unpublished record of *P. cephalica* (MVZ 138037, not examined by us), from Municipio Ciudad del Maíz: Mexican Hwy 80, 3.3 mi [5.3 km] E (by road) of Ciudad del Maíz (22.437063°N, 99.580134°W), 1371.6 m elev., and Johnson et al. (1978) also recorded *P. scandans* (= *P. scandens*) in San Luis Potosí: 27.7 km NE Ciudad del Maíz [22.466667°N, 99.516667°W, 1200–1400 m elev.] in the same area, collectively closing this gap by 36%. Further collecting is needed in the Sierra Madre Oriental of southeastern San Luis Potosí to determine the precise distribution of *P. cephalica* (and *P. belli* and *P. scandens*) in that state, and to determine if the Tamaulipas/San Luis Potosí populations are in fact isolated from the Hidalgo and southern populations.

Anura

Anaxyrus cognatus (Great Plains Toad). Municipio Tula: Near Ejido San Pablo 15 km SW of Tula (22.903056°N, 99.823056°W), 1064 m elev. 12 October 2007. William L. Farr. Verified by Fernando Mendoza-Quijano. UANL 6462–63. First state records, easternmost locality reported in México, and a range extension of ca. 60–70 km SE of the nearest site in Nuevo León (Krupa 1990). Additional specimens were observed AOR at and near this locality on this same night. The vegetation in the area is Chihuahuan Desert scrub.

Anaxyrus debilis (Green Toad). Municipio Xicoténcatl: 16 km E of Xicoténcatl on the road to Fortín Agrario (23.041667°N, 98.793056°W), 138.9 m elev. 18 September 2006. Toby Hibbitts, William Farr, and James R. Dixon. Verified by Fernando Mendoza-Quijano. UANL 6464–65. These records extend the range ca. 160 km S on the coastal plain of Tamaulipas (Savage 1954). The map in Savage (1954) included only one locality from Tamaulipas (a literature record from the central coast) and only shaded areas north of that locality; most subsequent sources (e.g., Conant and Collins 1998; IUCN 2006; Morafka 1977) follow this distribution pattern. Savage (1954) also speculated that the toad may range into extreme northern Veracruz, as did Sanders and Smith (1951) without supporting localities for the area south of 6 mi. [9.6 km, road?] SW of Jiménez [24.15333°N, 98.552778°W, 111 m elev.] in central Tamaulipas. We are unaware of any confirmed records from extreme northern Veracruz, or adjacent areas of San Luis

Potosí east of the Sierra Madre Oriental, but its occurrence there seems plausible based on habitat associations. We are aware of 48 additional museum records from 16 localities within Tamaulipas deposited subsequent to Savage (1954) (26 specimens from nine localities were examined by us), and those and personal observations from throughout the coastal plain confirm previous contentions of an extended southward distribution.

The two toads were collected from a small chorus observed in a roadside ditch after an early evening rain. The area is predominantly sugarcane fields with some elements of tropical thorn scrub and thorn forest. Martin (1958) speculated that this region of the state, which was predominantly sugarcane fields even then, may originally have included extensive grassland.

Gastrophryne elegans (Elegant Narrow-mouthed Toad). Municipio Ocampo: 4.5 km. N of Ocampo on the road to El Tigre (22.885833°N, 99.335°W), 348 m elev. 13 October 2007. William Farr. Verified by Fernando Mendoza-Quijano. UANL 6466. This is the second record from the state, first municipality record, and a 154 km range extension W from Rancho Los Colorados, 26 km NE Aldama [22.908333°N, 97.841667°W, 5 m elev.] in the municipality of Aldama (Sampablo-Brito and Dixon 1998). The species occurs in isolated and disjunct populations on the Atlantic versant of México southward to Honduras, and collectively, the records from Tamaulipas are isolated from the nearest confirmed locality ca. 280 km to the south in central Veracruz (Nelson 1972). We have observed *G. elegans*, sometimes in large choruses, in the municipalities of Aldama, Antiguo Morelos and Ocampo, all positioned on the Gulf Coastal Plain in the southern end of the state. Its occurrence should be anticipated in some of the adjacent municipalities (Altamira, El Mante, Gonzalez, Nuevo Morelos, and Tampico) in-between and south of the confirmed localities in the state. The toad reported here was found under a dead log in tropical deciduous forest.

Hypopachus variolosus (Sheep Frog). Municipio Reynosa: 30 km SW of junction of Hwy 40 and Hwy 2 in Reynosa (25.868333°N, 98.459167°W), 109 m elev. 8 October 2007. William Farr. Verified by Michael R. J. Forstner. UTADC 1943. This verified record fills a distributional gap of ca. 200 km between the south Texas population and the closest Mexican population in central Tamaulipas (AmphibiaWeb 2009; Conant and Collins 1998; Judd and Irwin 2005; Santos-Barrera et al. 2008). Nelson (1974) did not discuss or identify a distributional gap in this species' range in Tamaulipas, and in fact included a locality from this region, 28 km NNW of San Fernando (TCWC), although no museum number was given. It was probably TCWC 27722 from [Municipio San Fernando] 17.6 mi [28.3 km] NNE, 6.5 mi [10.45 km] (road miles) NNW of San Fernando [25.125°N, 98.155556°W] collected by C. A. Ketchersid and J. R. Dixon on 31 August 1968 (examined by authors). Additionally, we observed a chorus of *H. variolosus* in the municipality of Méndez, 5 km N of La Noria (25.461667°N, 98.226667°W, 60 m elev.). The lack of records from northern Tamaulipas probably reflects a collecting bias or prior extirpation of populations in this largely agricultural area, rather than a natural hiatus in the species' distribution. The frog was caught AOR after a rain in thorn scrub habitat.

Lithobates catesbeianus (American Bullfrog). Municipio El Mante: Near Tantoyuquita, 45 km SE of Ciudad Mante (22.550278°N, 98.574722°W), 25.2 m elev. 17 October 2007. William Farr. Verified by Fernando Mendoza-Quijano. UANL 6467. Municipio González: near López Rayón, 32 km S of González (22.5325°N, 98.397778°W), 46.8 m elev. 17 October 2007. William Farr. Verified by Michael R. J. Forstner. UTADC 1946. Municipio Gómez Farías: in an irrigation canal, 8 km S of Gómez Farías (22.973611°N, 99.122778°W), 102.3 m elev. 23 May 2005. William Farr, Adam Ferguson and David Rodríguez. Verified by Michael R. J. Forstner. UTADC 1945. New municipality records for each, and range extensions of 74 km NW, 56 km NW, and 145 km NW, respectively, from the vicinity of Altamira [22.358333°N, 99.12778°W, ca, 15 m elev.] (Morafka 1977). The vegetation types south of Gómez Farías are tropical deciduous and gallery forest, and the predominant vegetation type in the municipalities of González and El Mante localities is tropical thorn scrub, with some marshlands in low areas.

The distribution of *L. catesbeianus* in northeastern México and its purported range in Tamaulipas and the neighboring states of Nuevo León and Coahuila has not been carefully examined or well documented. Numerous publications and other sources, including Bury and Whelan (1984), IUCN (2006), and partial maps in Conant and Collins (1998) and Stebbins (2003) imply the distribution is widespread and continuous in Tamaulipas east of the Sierra Madre Oriental from the Río Grande to northern Veracruz. However, Morafka (1977), depicting the only map to record actual localities, showed one isolated site for the state in the vicinity of Altamira north of Tampico. Field surveys, literature, and museum records available to us confirm that Morafka (1977) is most accurate. All locality records known to us are discussed below.

Jean Louis Berlandier, *fide* Smith et al. (2003), noted *L. catesbeianus* in the vicinity of the Río Grande and Matamoros sometime between 1829 and 1851 in unpublished manuscripts now archived in the Smithsonian Institution. Kellogg (1932) appears to have published the first confirmed record of the species in Tamaulipas and stated the range as "probably" the coastal lowlands of Tamaulipas and northern Veracruz, but only documented two localities for México (mapped in Morafka 1977): Altamira, Tamaulipas (USNM 47114, verified by Steve Gotte) collected by Nelson and Goldman in 1898 and near Cadereyta, Nuevo León (USNM 3340), which included three larva and two adults (not examined by us); the adults were later recatalogued as USNM 344032–344033, collected by Couch in 1853. It appears that many subsequent authors accepted this presumed distribution without question. Only four additional museum records of *L. catesbeianus* from the state are known to us and all are from the municipality of Altamira (not examined by authors): AMNH A-165003, 1.6 mi. [2.5 km] NW Tres Marias; KU 51349–51350, 4 mi. [6.4 km] S Altamira; and OKMNH 26471, 9.0 mi. [14.5 km] N Tampico. Although expressed differently, the KU and OKMNH localities are approximately the same [22.358333°N, 97.891667°W, ca. 15 m elev.] and roughly correspond to the one Tamaulipas locality referred to in Morafka (1977) and Kellogg (1932). The AMNH locality is located 21 km NW of there [22.488889°N, 98.031944°W]. In field surveys, we have occasionally encountered *L. catesbeianus* along the Texas border only a few kilometers south of the Río Grande in the northwest "panhandle" region of Tamaulipas. We also observed a few others and photographed one individual on 23 May 2005 in irrigation canals 8 km S of Gómez Farías. Locals informed us that

those frogs had ether escaped or were released after failed attempts to farm them in the area. Martin's (1958) comprehensive surveys of the region did not record the species, so it can be assumed the introductions took place after his field surveys ended in 1953. Also, at least 12 bullfrogs were observed in roadside ditches, ponds, marshes, canals, and AOR at various localities on 17 October 2007 in the municipalities of González and El Mante.

With a distributional gap of over 375 km between records from the municipality of Altamira and observations from near the Río Grande and Matamoros from Berlandier's and our current surveys, we wonder if the Altamira population may have been introduced there as well, and whether our new records for the species in the adjacent municipalities of González and El Mante reflect dispersal northward and westward from that area. Nelson and Goldman's 1898 record (Kellogg 1932) seems early for the introduction of an alien species, however commercial frog farming dates back at least to 1914 (Randel 1914). Alternatively, the isolated and disjunct records for *L. catesbeianus* from northeastern México, including Berlandier's report from Saltillo, Coahuila (Smith et al. 2003), could represent relict populations from a formerly wider distribution; *Sistrurus catenatus* exhibits a similar distributional pattern in northeastern México.

We are unaware of any records from Nuevo León other than the Couch record (Kellogg 1932) cited above. Although we have not performed an exhaustive search of literature for that state we did query 23 institutions for records (ANSP, APSU, CAS, CM, CU, DMNH, UF, FMNH, KU, LACM, LSUS, MPM, MSUM, OKMNH, SRSU, TNHC, UANL, UAZ, UCM, UIMNH, UMMZ, USNM, UTEP), and these, as well as current queries of HerpNET, and many years of collecting and field experience by one of us (DL), yielded no additional localities for that state other than the Couch (Kellogg 1932) record cited above. Similarly, Smith et al. (2003) noted major distributional discrepancies between what is commonly indicated in current literature for Coahuila versus actual localities; the species was not included among that state's herpetofauna by Lemos Espinal and Smith (2007a).

Testudines

Trachemys venusta (Meso-American Slider). Municipio Camargo: below the overflow spillway of Presa R. Marte Gómez, 14.5 km SW of Camargo (26.225°N, 98.902778°W), 70.2 m elev. 21 May 2005. William Farr, Adam Ferguson, and David Rodríguez. Verified by Michael R. J. Forstner. UTADC 1947–50. On the road from El Azúcar to Santa Gertrudis 17 km SE of Camargo (26.1675°N, 98.764167°W), 45 m elev. 14 May 2006. William Farr. Verified by Michael R. J. Forstner. UTADC 1951–53. New municipality records, northernmost localities for the species, and range extensions in Tamaulipas of ca. 139 km and 126 km NW, respectively, from the nearest record, 4.5 mi. [7.2 km] N of Santa Teresa (Seidel et al. 1999); recorded in Auth et al. (2000) as 4 mi. [6.4 km] N of Santa Teresa [Municipio San Fernando (25.335833°N, 97.875°W), 9 m elev.]. Both localities are in thorn scrub and located in the Río Grande drainage.
